Medical Action and Uses.—The acid and aromatic taste of this plant and its odor, resembling that of angelica, depend upon its essential oil, and to the stimulating operation of this oil nearly all the medicinal virtues of the medicine are due. It is but little used at the present day, but it was formerly prescribed in various conditions of local or general debility. Among these were the *typhoid state* of fevers and inflammations, *intermittent fever*, *delirium tremens*, and some forms of *dropsy*, *atonic dyspepsia*, *flatulent colic*, *hysteria*, and *asthma*; and locally it was used as a masticatory to relieve *toothache* and *paralysis* of the tongue or palate and as a stimulant of unhealthy ulcers. It may be administered in an infusion made with from 5 to 10 parts of the root and 100 parts of hot water.

Imperatoria Ostruthium, *Linne*: root-stock, natural size; and transverse section, natural size and magnified.

INDIGO.—INDIGO.

Indicum, *Pigmentum indicum*.—*Indigo*, Fr., G.

A blue dye-stuff extracted from different species of *Indigofera*. Bentley and Trimen. *Med. Plants*, 72.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—The genus consists of herbaceous or suffruticose plants which are indigenous to and cultivated in tropical and subtropical countries. The most important species are *Indigofera tinctoria*, *Linne* (s. l. *indica*, *Lamarck*), *I. Anil*, *Linne*, and *I. argentea*, *Linne* (s. l. *glauca*, *Lamarck*, *I. cærulea*, *Rosburgh*). The genus *Baptisia* appears to yield a similar coloring matter. Indigo is also obtained from *Isatis tinctoria*, *Linne* (*Nat. Ord.* Crucifere), the *woad*, indigenous to Europe, and from *Polygonum tinctorium*, *Linne* (*Nat. Ord.* Polygonaceæ), which is a native of China.

Preparation.—The plants are immersed in water until fermentation has set in, whereby the chromogene is dissolved. When the liquid has assumed a sherry color it is drawn off and briskly stirred, so as to bring it freely into contact with air. As the chromogene becomes oxidized the newly-formed coloring matter, which is insoluble in water, subsides. The supernatant liquid is then decanted, and the deposit heated to boiling to arrest fermentation, after which the precipitate is collected, pressed, and dried. Nearly 1,000,000 pounds of indigo were imported into the United States in 1876, and over 3,000,000 pounds in 1882.

Properties.—Indigo is met with in porous, hard, but brittle lumps or cubical cakes, which are inodorous, tasteless, and of a deep-blue color, assuming a coppery lustre when scratched or rubbed with a hard body; inferior qualities are of a dull hue, with a greenish or grayish tint, dense, firm, and not brittle. It is insoluble in the ordinary solvents, dissolves freely in concentrated sulphuric acid, and when rapidly heated sublimes partly in purple-colored vapors which condense into copper-colored needles. The color of indigo is altered by oxidizing and deoxidizing agents.

Constituents.—Indigo contains variable quantities of inorganic substances; when of good quality it yields about 7 per cent. of ash. It contains the proteid *indigo-gluten*, which is soluble in warm diluted acids, and the coloring principles *indigo-brown*, soluble in caustic alkalies, and *indigo-red* or *indigo-resin*, which is taken up by boiling alcohol

after the indigo has been previously exhausted with dilute acids and alkalies. But the most important principle is *indigo-blue* or *indigotin*, of which good indigo contains between 50 and 60 or 70 per cent., and which is not contained in the plants, but is formed from a colorless syrupy bitterish compound called *indican*, $C_{26}H_{33}NO_{18}$. During the treatment described above indican is split into a saccharine body, *indigluvin*, $C_6H_{10}O_6$, and indigotin, $C_{16}H_{10}N_2O_2$. On mixing 2 or 3 parts of finely-powdered indigo, 6 parts of slaked lime, 4 parts of ferrous sulphate, and 450 parts of boiling water the blue color disappears, and the yellow solution contains *indigo-white*, $C_{16}H_{12}N_2O_2$, which may be obtained as a white crystalline powder on adding the clear solution to an excess of boiled dilute hydrochloric acid with the precaution to avoid all contact with the air; if access of air be permitted during the latter part of this process, indigotin is regenerated and deposited in the form of a deep-blue powder. By oxidation of indigotin with nitric acid, *isatin*, $C_{16}H_{10}N_2O_4$, is obtained, forming yellowish-red shining, bitter prisms which are soluble in alcohol, hot water, and alkalies, and on distillation with potassa yield *aniline*.

Soluble indigo, or *sulphate of indigo*, is prepared by gradually adding 1 part of powdered indigo to 5 parts of Nordhausen sulphuric acid or 8 parts of oil of vitriol, and preventing a rise of temperature by immersing the vessel in cold water. In the course of 2 or 3 days it becomes a dark-blue pasty mass, the solution of which in about 2 parts of water is *liquid blue*. The solution of indigo in sulphuric acid contains two compounds—*sulpho-purpuric acid* or *indigo-purple*, $C_{16}H_9N_2O_2.HSO_3$, and *sulphindigotic* or *sulphocarmic acid*, $C_{16}H_8N_2O_2(HSO_3)_2$; the first one of these is insoluble in dilute acids, in which the second remains dissolved, and is obtained pure by transferring it from its dilute solution to wool and dissolving it from the latter by means of a weak alkali. Its salts are amorphous; those with potassium and sodium are sold in commerce as *indigo-carmine*, and are usually obtained by adding a potassium or sodium salt to a solution of sulphate of indigo, washing the precipitate with a solution of the same salt, and expressing; the product is soluble in pure water.

Artificial Indigo.—The synthetical preparation of indigo has been the subject of research for a series of years, and was finally accomplished by Prof. Adolf Baeyer (1878) by converting toluol, through a number of intermediate products, into isatin, and finally into indigotin. This elaborate process not promising commercial success, a more direct one, which is now in successful operation, was devised by the same chemist, starting with cinnamic acid prepared from coal-tar. It is converted by nitric acid into *nitro-cinnamic acid*, $C_6H_5(NO_2)C_2H_2COOH$; this with bromine yields *nitrodibrom-cinnamic acid*, $C_6H_4(NO_2)C_2H_2Br_2COOH$, which, by the action of caustic alkali, parts with bromine and hydrogen and leaves *orthonitrophenyl-propionic acid*, $C_6H_4(NO_2)C_2COOH$. On heating this with an alkaline solution of grape-sugar, which acts as a reducing agent, oxygen and carbonic dioxide are eliminated, and indigotin ($C_{16}H_{10}N_2O_2$) is produced.

Valuation.—This is based upon determining approximately the amount of indigotin contained in indigo by the process given above, or by adding chlorine ($KClO_3$ and HCl) to finely-powdered indigo until the blue color has been destroyed. The richer it is in indigotin the larger will be the amount of chlorine necessary to effect decolorization.

Adulteration.—Indigo may be adulterated with water, which the better qualities readily absorb; when dried at $100^\circ C.$ ($212^\circ F.$) it should lose not over 6 per cent. in weight. The best qualities of indigo leave from 4 to 8 per cent. of ash when incinerated; a larger percentage indicates admixture of inorganic matter. Gum or starch, if present, forms with hot water a mucilaginous liquid or paste, and if treated with strong sulphuric acid is carbonized, coloring the indigo black. Adulteration with Prussian blue is detected with caustic potassa or soda, which does not alter indigo, but liberates from Prussian blue ferric hydrate, while potassium or sodium ferrocyanide remains in solution.

Pharmaceutical Uses.—Besides its uses in the arts for dyeing, a solution of indigo is employed as a test for determining the presence of nitric acid, chlorine, etc.

Medical Action and Uses.—During the experiments made many years ago with indigo in the treatment of *epilepsy*, it was given in very large doses, and, as a consequence, deranged the digestive organs, causing vomiting and purging, with debility and some nervous disorder. In some instances the urine and sweat acquired a bluish color. There is not the slightest ground for believing that it exhibits curative virtues in epilepsy or in any other disease. Its dose is usually stated to be from 5 to 15 grains and upward.

INFUSA, U. S., Br., P. G.

Infusions, E., Fr.; Infusés, Fr.; Infusionen, Aufgüsse, G.

Infusions are aqueous solutions of the soluble principles of vegetable or animal drugs obtained by maceration or digestion in hot or cold water, and differ from decoctions only in the lower degree of heat employed in their preparation. Substances containing volatile or other principles which would be dissipated or injured by boiling are particularly adapted for this purpose. Except in a few cases in which percolation is directed, the pharmacopœial infusions are prepared by pouring boiling or cold water upon the material and allowing them to remain in contact for a definite length of time, at the expiration of which the solution is poured upon a strainer, and the solid material expressed to recover the liquid absorbed by it. A convenient apparatus, well adapted for making these preparations, is Squire's infusion-pot: this consists of a jar A, with a projecting ledge near the top, which supports a strainer, B or D, containing the material to be exhausted; the jar is closed by a well-fitting cover, C. The advantages of this contrivance are—that the material is exhausted by circulatory displacement, the liquid, as it becomes charged with the soluble ingredients descending to the bottom, giving place to fresh portions of less saturated menstruum, and that no further straining is required should care have been taken not to use too fine a powder.

The drugs are best adapted for exhaustion with water if cut into thin slices by a suitable knife, so that they may be easily permeated by the liquid; when cutting is inadmissible they should be bruised to a coarse powder. Ligneous drugs, however, should be in a fine or moderately fine powder, which is also best adapted for most of those which may be made by percolation.

The time directed for the maceration with boiling water is, in the U. S. Pharmacopœia, usually 2 hours, and in the British Pharmacopœia 15 or 30 minutes, which is in most cases sufficient.

The strength of the infusions of the British Pharmacopœia is usually such that the virtues of 1 part of the drug are represented by 20 or 40 parts of the infusion; the simple infusions for which special directions are given in the U. S. Pharmacopœia are made in the proportion of $1\frac{1}{2}$, 4, or 6 parts to 100 parts by weight. The French Codex classifies these preparations according to their strength, and designates such, 100 or 200 parts of which represent 1 part of the drug, as *tisanes*, *ptisanæ*; they are made either by maceration, infusion, or decoction, and are intended to be used freely. *Bouillons* are similar preparations made from lean meat, with or without the addition of aromatics and other substances. *Apozèmes* are infusions or decoctions differing from tisanes only in being more concentrated.

Infusions are not intended to be kept, except for a very limited period. Exposed to air, as they necessarily must be in the sick chamber through the vial containing them being opened from time to time, decomposition must ensue after a day or two, and may be retarded somewhat only by keeping the vessel in a cool place, or, better still, on ice. When desirable to have a larger quantity prepared the liquid may be preserved by *Appert's method*: it is put into convenient-sized vials, which are heated by a water-bath gradually to the boiling-point, and stopped at that temperature. However, considering that infusions are rarely made by the pharmacist, but are usually prepared by the attendants of the patient, and may be frequently made as required, there is little necessity for such a course or for any of the various contrivances that have been proposed for obviating fermentation and other changes in infusions. But for the physician it may be useful to know that most of the infusions may be prepared in a more concentrated form, or reduced in volume by evaporation at a moderate heat, and then be kept unaltered for a considerable time by the addition of one-third their volume of alcohol. Dissolving $\frac{1}{2}$ grain of salicylic acid in each fluidounce of the infusion will have a similar preservative effect.

Nearly all the infusions will yield precipitates or become discolored with the salts of

FIG. 159.

Squire's Infusion-Pot.

iron, lead, mercury, silver, and other heavy metals, and are therefore incompatible with them.

The U. S. Pharmacopœia has adopted the plan of the German Pharmacopœia in ordering all infusions, unless otherwise directed by the physician, and with the exception of five specially enumerated, to be made of 1 part of material to 10 parts of infusion, according to the following directions: "An ordinary infusion, the strength of which is not directed by the physician nor specified by the pharmacopœia, shall be prepared by the following formula: Take of the substance, coarsely comminuted, 10 parts; boiling water 100 parts; water a sufficient quantity; to make 100 parts. Put the substance into a suitable vessel provided with a cover, pour upon it the boiling water, cover the vessel tightly, and let it stand 2 hours. Then strain, and pass enough water through the strainer to make the infusion weigh 100 parts. *Caution.*—The strength of infusions of energetic or powerful substances should be specially prescribed by the physician."

The Pharmacopœia omits to direct the expression of the drug after infusion, but it is evident that bulky herbs and flowers, which are best adapted to this process, would retain a considerable proportion of the liquid, which cannot be washed out simply by passing water through the strainer to make up the deficiency in weight. Allowing from 20 to 25 per cent. of the weight of the drug to be dissolved on an average by the boiling water, the 40 oz. av. of infusion obtained from 4 oz. of drug will measure 38 fluidounces; accordingly,

	$\frac{1}{4}$	$\frac{1}{2}$	$\frac{3}{4}$	1	1 $\frac{1}{2}$	2	2 $\frac{1}{2}$	3	3 $\frac{1}{2}$	4 oz. av. of drug
will make	2 $\frac{3}{8}$	4 $\frac{3}{4}$	7 $\frac{1}{8}$	9 $\frac{1}{2}$	14 $\frac{1}{4}$	19	23 $\frac{1}{4}$	28 $\frac{1}{2}$	33 $\frac{1}{4}$	38 fluidounces
of infusion, or there will be required										
for 1	2	3	4	5	6	8	10	12	16 fluidounces	
46	92	138	184	230	276	368	460	552	736 grains of drug.	

The general directions for infusion given by the German Pharmacopœia are nearly identical with the above, from which they differ only in this, that the mixture of drug and boiling water is heated for 5 minutes in a vapor-bath of boiling water, occasionally stirred, allowed to cool, and strained. The *concentrated* and *highly-concentrated infusions*, made respectively with 1 $\frac{1}{2}$ and 2 parts of drug to 10 parts of infusion, are no longer recognized.

INFUSUM ANTHEMIDIS, *Br.*—INFUSION OF CHAMOMILE.

Infusum chamomillæ romanæ.—*Tisane de chamomille romaine*, Fr.; *Römisch-Kamillenthe*, G.

Preparation.—Take of Chamomile-Flowers $\frac{1}{2}$ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—*Br.*

A fluidounce of this infusion represents 15 grains U. S. 1870. 22 grains *Br.*, or 46 grains of chamomile, if made by the general formula above.

Medical Uses.—The *dose* of this infusion is about a wine-glassful (Gm. 64) before meals; it is more apt to agree with the stomach when made with cold water. The infusion, when warm, is an efficient and gentle emetic.

INFUSUM AURANTII, *Br.*—INFUSION OF ORANGE-PEEL.

Tisane d'écorce d'orange, Fr.; *Pomeranzenschalen-Aufguss*, G.

Preparation.—Take of Bitter Orange-Peel, cut small, $\frac{1}{2}$ ounce; Boiling Distilled water 10 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—*Br.*

Medical Action and Uses.—This infusion may be prescribed to allay pain and flatulence in *colic* and as a vehicle for other medicines, particularly magnesia. *Dose*, 1 or 2 fluidounces (Gm. 32–64).

INFUSUM AURANTII COMPOSITUM, *Br.*—COMPOUND INFUSION OF ORANGE-PEEL.

Tisane d'écorce d'orange composée, Fr.; *Pomeranzen- und Citronenschalen-Aufguss*, G.

Preparation.—Take of Bitter Orange-Peel, cut small, $\frac{1}{2}$ ounce; Fresh Lemon-Peel, cut small, 56 grains; Cloves, bruised, 28 grains; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—*Br.*

Medical Action and Uses.—The compound infusion of orange-peel is a grateful carminative, appropriate in *flatulence* and also in slight *diarrhœa* caused by indigestion. *Dose*, 1 or 2 fluidounces (Gm. 32–64).

INFUSUM BRAYERÆ, *U. S.*—INFUSION OF BRAYERA.

Infusum cusso, Br.—*Infusion of kouso*, E.; *Apozème de couso*, Fr.; *Kossotrank*, G.

Preparation.—Brayera, in No. 20 powder, 6 parts ($\frac{1}{2}$ oz. av.); Boiling Water 100 parts ($\frac{8}{3}$ oz. av. or 8 fluidounces). Pour the boiling water upon the brayera, and let it macerate in a covered vessel until cool. This infusion should be dispensed without straining.—*U. S.*

Kouso, in coarse powder, $\frac{1}{2}$ ounce; boiling distilled water 8 fluidounces. Infuse in a covered vessel for 15 minutes, without straining.—*Br.* Kouso 20 Gm.; boiling water 150 Gm.—*F. Cod.*

Medical Uses.—About 4 fluidounces (Gm. 130) form the appropriate *dose* used in the treatment of *tape-worm*.

INFUSUM BUCHU, *Br.*—INFUSION OF BUCHU.

Infusum diosmæ s. barosmæ.—*Tisane de bucco*, Fr.; *Buchuaufguss*, G.

Preparation.—Take of Buchu-Leaves, bruised, $\frac{1}{2}$ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

A fluidounce of this infusion represents 22 grains *Br.*, 30 grains *U. S.* 1870, or 46 grains of buchu if made by the general formula given above.

Medical Uses.—This preparation contains all the virtues of buchu, and is preferable to more concentrated forms of the medicine. *Dose*, 1 to 2 fluidounces (Gm. 32–64). It is usual to make an infusion with equal proportions of buchu and uva ursi.

INFUSUM CALUMBÆ, *Br.*—INFUSION OF CALUMBA.

Infusion of columbo, E.; *Tisane de colombo*, Fr.; *Kolombo-Infusion*, G.

Preparation.—Take of Calumba-Root, cut small, $\frac{1}{2}$ ounce; Cold Distilled Water 10 fluidounces. Macerate in a covered vessel for 30 minutes, and strain.—*Br.*

The infusion made with hot water is much more mucilaginous and unsightly than if made with cold water, either by maceration or percolation. Each fluidounce represents 15 grains *U. S.* 1870, 22 grains *Br.*, or 46 grains if made by the above general formula.

Medical Uses.—This is probably the most useful preparation of columbo if made with due precautions. *Dose*, a wine-glassful (Gm. 64) before meals.

INFUSUM CARYOPHYLLI, *Br.*—INFUSION OF CLOVES.

Tisane de girofle, Fr.; *Gewürznelken-Infusion*, G.

Preparation.—Take of Cloves, bruised, $\frac{1}{4}$ ounce; Boiling Distilled Water 10 fluidounces. Macerate in a covered vessel for 30 minutes, and strain.—*Br.*

1 fluidounce of this infusion represents $7\frac{1}{2}$ grains *U. S.* 1870, 11 grains *Br.*, and if made ready by the general formula, 46 grains.

Medical Uses.—Infusion of cloves is used to allay flatulent colic and nausea from exhaustion. *Dose*, a tablespoonful (Gm. 16).

INFUSUM CASCARILLÆ, *Br.*—INFUSION OF CASCARILLA.

Tisane de cascarrille, Fr.; *Kaskarilla-Aufguss*, G.

Preparation.—Take of Cascarilla-Bark, in No. 20 powder, 1 ounce; Boiling Distilled Water 10 fluidounces (Imperial measure). Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

This is of precisely the strength as indicated by the general formula on page 816; made by the Pharmacopœia of 1870, it was two-thirds this strength.

Medical Uses.—Cascarilla is best administered in this form. It may be given in *doses* of 2 fluidounces (Gm. 64) two or three times a day.

INFUSUM CATECHU, *Br.*—INFUSION OF CATECHU.

Infusum catechu compositum, U. S. 1870.—*Compound infusion of catechu*, E.; *Tisane de cachou composée*, Fr.; *Catechuaufguss mit Zimmt*, G.

Preparation.—Take of Pale Catechu, in coarse powder, 160 grains; Cinnamon-Bark, bruised, 30 grains; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

This infusion, made by the U. S. P. 1870, was practically identical with the preceding. Made by the present general formula, it would be three times the above strength.

Medical Uses.—The addition of cinnamon to catechu in this preparation increases its astringency, and renders it stimulant and anodyne at the same time. It is a convenient remedy for diarrhœa with flatulent colic, provided the bowels are free from irritating ingesta. *Dose*, from 1 to 3 fluidounces (Gm. 32–96).

INFUSUM CHIRATÆ, *Br.*—INFUSION OF CHIRETTA.

Tisane de chirette, Fr.; *Chiretta-Thee*, G.

Preparation.—Take of Chiretta, cut small, $\frac{1}{4}$ ounce; Distilled Water, at 120° F., 10 ounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

Medical Uses.—This infusion resembles that of quassia in its qualities, and may be used where simple bitters are needed, in the *dose* of 2 or 3 fluidounces (Gm. 64–96).

INFUSUM CINCHONÆ, *U. S.*—INFUSION OF CINCHONA.

Infusum cinchonæ acidum, *Br.*—*Acid infusion of cinchona*, E.; *Tisane acidulée de quinquina*, Fr.; *Saurer China-Aufguss*, G.

Preparation.—Cinchona, in No. 40 powder, 6 parts (1 oz. av.); Aromatic Sulphuric Acid 1 part (73 grains or 72 minims); Water a sufficient quantity; to make 100 parts. Mix the acid with 50 parts ($8\frac{1}{2}$ oz. av. or 8 fluidounces) of water, and moisten the powder with 3 parts ($\frac{1}{2}$ oz. av.) of the mixture; pack it firmly in a conical glass percolator, and gradually pour upon it first the remainder of the mixture, and afterward water until the infusion weighs 100 parts (16 $\frac{2}{3}$ oz. av. or 1 pint). When no variety of cinchona is specified by the physician directing this infusion, use yellow cinchona.—*U. S.*

Red cinchona-bark, in No. 20 powder, $\frac{1}{2}$ oz. (1 part); aromatic sulphuric acid 1 fl. drachm ($\frac{1}{4}$ fl. part); boiling distilled water 10 fl. oz. (20 fl. parts). Infuse in a covered vessel for 1 hour and strain.—*Br.*

The first process, if well conducted, obtains all the alkaloids of the bark in a soluble condition, and is, in point of fact, simply a solution of the sulphates of these alkaloids slightly weaker than that made by the Pharmacopœia of 1870. The second process will yield a very similar preparation, the straining being effected when cold. The chief difference between the two preparations is that in the former any good variety of cinchona may be employed, while for the latter red bark from cultivated plants is used.

Infusum cinchonæ flavæ, *Br.* 1867, was made with boiling water, no acid having been used. Such infusions, if strained while hot, will become turbid; and if strained after cooling are clear, but retain merely those alkaloids which in the natural combination are soluble in cold water.

Medical Uses.—The infusion of cinchona is used only as a tonic, and not as an anti-periodic, and may be prescribed in the *dose* of 2 fluidounces (Gm. 64) three times a day.

INFUSUM CUSPARIÆ, *Br.*—INFUSION OF CUSPARIA.

Infusum angusturæ, U. S. 1870.—*Infusion of cusparia*, E.; *Tisane d'angusture*, Fr.; *Angustura-Infusion*, G.

Preparation.—Take of Cusparia-Bark, No. 40 powder, $\frac{1}{2}$ ounce; Distilled Water, at 120° F., 10 fluidounces. Infuse in a covered vessel for 1 hour, and strain.—*Br.*

1 fluidounce of this infusion contains the virtues of nearly 22 grains *Br.*, 46 grains *U. S.* 1880 (15 grains *U. S.* 1870), of angustura-bark.

Medical Uses.—Following the Abyssinian mode of administering this vermifuge, the coarsely-powdered flowers are taken along with the water in which they are infused. The 8 fluidounces should be divided into two portions, and used with an interval of an hour between them in the morning, fasting.

INFUSUM DIGITALIS, *U. S., Br.*—INFUSION OF DIGITALIS.

Tisane de digitale, Fr.; *Fingerhutaufguss*, G.

Preparation.—Digitalis, in No. 20 powder, 3 parts (60 grains); Cinnamon, in No. 20 powder, 3 parts (60 grains); Boiling Water, 185 parts (3700 grains or 8½ fluidounces); Alcohol 15 parts (300 grains or 6½ fluidrachms); Water a sufficient quantity; to make 200 parts. Pour the boiling water upon the mixed powders, and macerate for 2 hours in a covered vessel. Then strain, add the alcohol, and pass enough water through the strainer to make the infusion weigh 200 parts (4000 grains or 8¾ fluidounces).—*U. S.*

Take of digitalis-leaves, dried, 28 grains; boiling distilled water 10 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—*Br.*

The bitter taste of digitalis is masked in the first preparation by the cinnamon, and the small quantity of alcohol and oil of cinnamon will preserve the infusion for several days before a precipitate makes its appearance, which probably contains a portion of the digitalin in combination with the tannin of the cinnamon. D. E. Prall (1878), however, did not succeed in isolating digitalin from the precipitate. 1 fluidounce of the infusion represents 3 grains *Br.*, 7 grains *U. S. P.* 1880 (7½ grains, *U. S. P.* 1870), of digitalis.

Medical Uses.—The infusion is probably the most certain diuretic preparation of digitalis. In the treatment of *dropsy* it should be steadily continued until it begins to act either upon the kidneys, the stomach, the pulse, or the bowels. Then, however, it ought at once to be suspended or the dose greatly lessened. Its physiological effects, it should be remembered, continue for several days after the medicine is discontinued, and its diuretic action occurs most readily during a state of rest. *Dose*, from ½ fluidounce to a fluidounce (Gm. 16–32) two or three times a day. A compound vinous infusion is a more efficient diuretic than the simpler official preparation; thus: White wine 750 parts; juniper-berries, bruised, 50 parts; digitalis 10 parts; squill 5 parts. Macerate for 4 days, and add acetate of potassium 15 parts. *Dose*, a tablespoonful (Gm. 16) three times a day.

INFUSUM DULCAMARÆ.—INFUSION OF DULCAMARA.

Tisane de douce-amère, Fr.; *Bittersüssaufguss*, G.

Preparation.—Take of Dulcamara, bruised, 1 ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 1 hour, and strain.—*Br.* 1867.

Medical Uses.—The infusion is probably the most efficient preparation of dulcamara. Its very dilution increases its activity. *Dose*, from 1 to 2 fluidounces (Gm. 32–64).

INFUSUM ERGOTÆ, *Br.*—INFUSION OF ERGOT.

Tisane de seigle ergoté, Fr.; *Mutterkornaufguss*, G.

Preparation.—Take of Ergot, in coarse powder, ¼ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

Medical Uses.—The *dose* of this preparation for a woman in *labor* is 1 to 2 fluidounces (Gm. 32–64). Each fluidounce (Gm. 32) contains about 10 grains (Gm. 0.60) of ergot.

INFUSUM GENTIANÆ COMPOSITUM, *Br.*—COMPOUND INFUSION OF GENTIAN.

Tisane de gentiane composée, Fr.; *Enzianaufguss*, G.

Preparation.—Take of Gentian-Root, sliced. Bitter Orange-Peel, cut small, each 55 grains; Fresh Lemon-Peel, cut small, ¼ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

Take of gentian, in moderately coarse powder, ½ troyounce; bitter orange-peel, in moderately coarse powder, coriander, in moderately coarse powder, each 60 grains; alcohol 2 fluidounces; water a sufficient quantity. Mix the alcohol with 14 fluidounces of water, and, having moistened the mixed powders with 3 fluidrachms of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them first the remainder of the menstruum, and then water, until the filtered liquid measures a pint.—*U. S.* 1870.

The first formula yields an agreeable preparation, which, however, does not keep as well as that made by the second formula, in which alcohol is present in sufficient quantity to preserve it unaltered for some days. As it is an elegant preparation, frequently prescribed

in small quantities, J. T. Shinn (1862) proposed to exhaust four times the weight of material directed by percolation with diluted alcohol sufficient for obtaining 1 pint of tincture, 4 fluidounces of which, diluted with 12 fluidounces of water, will exactly represent 1 pint of the infusion, as directed by the U. S. P. 1870. The preparation was dropped from the recent Pharmacopeia, perhaps for insufficient reasons. (See also MISTURA GENTIANÆ.)

Medical Uses.—This is an agreeable and efficient stimulant stomachic tonic, and may be used in *doses* of a fluidounce (Gm. 32) two or three times a day.

INFUSUM KRAMERIÆ, *Br.*—INFUSION OF RHATANY.

Tisane de ratanhia, Fr.; *Ratanha-Aufguss*, G.

Preparation.—Take of Rhatany-Root, in No. 40 powder, $\frac{1}{2}$ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

A fluidounce of this infusion, made by the U. S. P. 1870, represented 30 grains; made by the present general formula, 46 grains.

Medical Uses.—In all cases of internal *hæmorrhage* to which astringents are applicable this infusion may be advantageously used, the more so the more passive the bleeding. It is also useful in *mucous profluvia* of the *bronchia* and the *gastro-intestinal* tube. A watery solution of extract of rhatany is, however, generally preferable. *Dose*, 2 fluidounces (Gm. 64).

INFUSUM LINI, *Br.*—INFUSION OF LINSEED.

Infusum lini compositum, U. S. 1870.—*Infusion of flaxseed*, E.; *Tisane de lin*, Fr.; *Leinsamenaufguss*, G.

Preparation.—Take of Linseed 150 grains; Fresh Liquorice-Root, sliced, 50 grains; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 2 hours, and strain.—*Br.*

Liquorice-root is added in this infusion with the view of improving its flavor. As the mucilage is contained in the covering of the seed, it should not be bruised, otherwise the oil will be emulsified, and the swelling of the entire tissue will prevent the straining of the liquid.

Medical Uses.—The apparent intention of this preparation is to provide an appropriate remedy for acute mucous inflammations of the respiratory tract, an object which scarcely required a special formula, since in domestic practice it is customary to add extract of liquorice, sugar, or lemon-juice to flaxseed tea for these affections. The liquorice also renders the infusion less appropriate for bowel and urinary disorders, to which the simple flaxseed tea is generally well adapted. It may be drunk freely.

INFUSUM LUPULI, *Br.*—INFUSION OF HOP.

Infusum humuli, U. S. 1870.—*Tisane de houblon*, Fr.; *Hopfenaufguss*, G.

Preparation.—Take of Hop $\frac{1}{2}$ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 1 hour, and strain.—*Br.*

If made by the present general formula, the infusion will be of three times the strength as compared with that of the U. S. P. 1870.

Medical Uses.—It is the most eligible form for the administration of hop when alcohol is contraindicated. *Dose*, from 2 to 4 fluidounces (Gm. 64–128) every two or three hours.

INFUSUM MATICÆ, *Br.*—INFUSION OF MATICO.

Tisane de matico, Fr.; *Matico-Aufguss*, G.

Preparation.—Take of Matico-Leaves, cut small, $\frac{1}{2}$ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

Medical Uses.—This astringent but not very efficient preparation may be prescribed in *doses* of a fluidounce (Gm. 32) or more.

INFUSUM PRUNI VIRGINIANÆ, *U. S.*—INFUSION OF WILD CHERRY.

Tisane d'écorce de cerisier sauvage, Fr.; *Wildkirschen-Thee*, G.

Preparation.—Wild Cherry, in No. 40 powder, 4 parts ($\frac{1}{2}$ oz. av.); Water a sufficient quantity; to make 100 parts. Moisten the powder with 6 parts of water and mace-

rate for 1 hour; then pack it firmly in a conical glass percolator, and gradually pour water upon it until the infusion weighs 100 parts (12½ oz. av. or 12 fluidounces).—*U. S.*

Made with cold water as directed by the Pharmacopœia, this infusion contains volatile oil and hydrocyanic acid, which are not generated by the use of hot water. Its strength has been somewhat increased over that of 1870.

Medical Uses.—This is the best form in which wild-cherry bark can be used, as a mild tonic and a sedative of the *irritable heart*. It is also applicable to the treatment of irritative *dyspepsia*, *nervous cough*, the cough of early pulmonary *phthisis*, and the hectic irritation of the decline of that disease. *Dose*, 2 or 3 fluidounces (Gm. 64–96) several times a day.

INFUSUM QUASSIÆ, *Br.*—INFUSION OF QUASSIA.

Tisane de quassie, Fr.; *Quassia-Aufguss*, G.

Preparation.—Take of Quassia-Wood, in chips, 55 grains; Cold Distilled Water 10 fluidounces. Macerate in a covered vessel for 30 minutes, and strain.—*Br.*

We can perceive no objection to the use of warm water in making this infusion, whereby time might be materially economized without interfering with the appearance or efficiency of the preparation; maceration, as directed above, will yield a very bitter infusion, containing, however, only a portion of the quassia. If made by the general formula (see page 816), the infusion will be six times the strength of that directed by the *U. S. P.* 1870.

Medical Uses.—Infusion of quassia is the purest of bitter infusions, and is the best form for administering this useful stomachic tonic. The *dose* is 2 fluidounces (Gm. 64) three times a day.

INFUSUM RHEI, *Br.*—INFUSION OF RHUBARB.

Tisane de rhubarbe, Fr.; *Rhabarberaufguss*, G.

Preparation.—Take of Rhubarb-Root, in thin slices, ¼ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

Rhubarb being easily permeated by water, it is preferable to employ it for this purpose cut into thin slices, instead of bruising it; in the latter case the finer powder should be sifted off. But in either case the preparation is unsightly, and becomes still more so by long-continued digestion. A handsomer though weaker infusion is obtained with the formula of the French Codex, by maceration for 4 hours with cold water. In Germany a preparation has long been in use under the name of *Infusum rhei kalium* or *Tinctura rhei aquosa*, which is now prepared as follows: Rhubarb, sliced, 100 parts; borax and potassium carbonate, each 10 parts; boiling distilled water 900 parts. Infuse for 15 minutes, add alcohol 90 parts, and macerate for 1 hour; then express lightly, and to 850 parts of the liquid add cinnamon-water 150 parts. The finished preparation represents nearly 10 per cent. of rhubarb, is of a dark red-brown color, transparent in thin layers, mixes clear with aqueous liquids, and has not an alkaline reaction, but is incompatible with all preparations which are decomposed by alkalis. It may be preserved for several months if kept in small vials and in a cool place.

Medical Uses.—This infusion is seldom prescribed, either alone or as a vehicle for other purgatives. In the latter case it has been associated with salines, such as the tartrate of sodium or the bitartrate of potassium. The diluted form of this preparation is probably not without its advantages in maintaining a moderate and sustained operation on the bowels. *Dose*, 1 or 2 fluidounces (Gm. 32–64), repeated, if necessary, in three or four hours.

INFUSUM ROSÆ ACIDUM, *Br.*—ACID INFUSION OF ROSE.

Infusum rosæ compositum, *U. S.* 1870.—*Compound infusion of rose*, E.; *Tisane de rose composée*, Fr.; *Saurer Rosenaufguss*, G.

Preparation.—Take of Dried Red Rose Petals, broken up, ¼ ounce; Diluted Sulphuric Acid 1 fluidrachm; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

The Pharmacopœia of 1870 ordered red rose ½ troyounce; diluted sulphuric acid 3 fluidrachms; sugar 1½ troyounces; boiling water 2½ pints.

This infusion should not be made in a metallic vessel; it has a fine red color and agreeable flavor.

Medical Uses.—The compound infusion of rose is employed as a coloring and flavoring ingredient of mixtures, and as an excipient and solvent for sulphate of quinia and sulphate of magnesia, whose bitterness it partially covers. It forms an agreeable gargle for inflamed and ulcerated states of the *mouth* and *fauces*, and may be used to moderate profuse sweats. Its virtues are largely due to the sulphuric acid it contains. *Dose*, from 2 to 4 fluidounces (Gm. 64–128).

INFUSUM SENEGÆ, *Br.*—INFUSION OF SENEKA.

Tisane de polygale de Virginie, Fr.; *Senega-Aufguss*, G.

Preparation.—Take of Senega-Root, in No. 20 powder, $\frac{1}{2}$ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

Medical Uses.—This preparation is supposed to possess certain advantages over the decoction of seneka (*U. S. P.* 1870), which was originally prescribed, and continues to be preferred in this country; but as the senegin is not altered by the heat of boiling water, it is probable that the decoction extracts a larger proportion of it than infusion does. *Dose*, 1 to 2 fluidounces (Gm. 32–64).

INFUSUM SENNÆ COMPOSITUM, *U. S.*—COMPOUND INFUSION OF SENNA.

Infusum Sennæ, *Br.*—*Infusion of senna*, E.; *Tisane de séné composée*, Fr.; *Senna-Aufguss*, G.

Preparation.—Senna 6 parts (180 grains); Manna 12 parts (360 grains); Sulphate of Magnesium 12 parts (360 grains); Fennel, bruised, 2 parts (60 grains); Boiling Water 100 parts (3000 grains or $6\frac{1}{2}$ fluidounces); Water a sufficient quantity; to make 100 parts. Pour the boiling water upon the solid ingredients, and macerate in a covered vessel until cool. Then strain, and add enough water through the strainer to make the infusion weigh 100 parts (3000 grains or 6 fluidounces).—*U. S.*

Take of senna 1 ounce; ginger, sliced, 28 grains; boiling distilled water 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

The first formula yields a preparation which is equivalent to the *black draught* of British pharmacy, and is recognized as such by the *U. S. Pharmacopœia*. The manipulation directed is very wasteful and faulty, since more than 20 per cent. of the active matter is left behind. The senna and fennel should be treated with 80 parts (2400 grains or $5\frac{1}{4}$ fluidounces) of boiling water, the infusion expressed, and the manna and magnesium sulphate dissolved in the liquid; the solution may then be strained and the proper weight obtained by passing water through the senna.

The second formula may be regarded as yielding a simple senna infusion, containing merely a corrective. Long-continued contact with hot water appears to increase the tendency of the senna to produce griping, particularly if digestion be resorted to. If the leaves have been cut or bruised, digestion for not over 10 minutes will yield an active infusion. The flavor being a matter of taste, the selection of aromatics had probably best be left to the physician.

MISTURA SENNÆ COMPOSITA, *Br.*; POTIO PURGANS ANGLORUM, s. POTIO NIGRA. By these titles *black draught* is sometimes prescribed, which in Great Britain is made by dissolving 4 ounces of magnesium sulphate in 15 fluidounces of infusion of senna, and adding 1 fluidounce of liquid extract of liquorice, $2\frac{1}{2}$ fluidounces of tincture of senna, and $1\frac{1}{2}$ fluidounces of compound tincture of cardamoms.

POTION PURGATIVE, MÉDECINE NOIR, *P. Cod.* Senna 10 Gm.; rhubarb 5 Gm.; boiling water, 120 Gm.; infuse for 30 minutes, express, and dissolve sodium sulphate 15 Gm. and manna 60 Gm.

TISANE ROYALE, *P. Cod.* Senna, sodium sulphate, and fresh parsley-leaves, each 15 Gm.; anise and coriander, each 5 Gm.; 1 lemon, sliced; cold water 1000 Gm.; macerate for 24 hours.

INFUSUM SENNÆ COMPOSITUM, *P. G.*, also known as *Aqua (s. Potio) laxativa Viennensis*—Vienna draught, E.; *Eau laxative de Vienne*, Fr.; *Wiener Trank*, G.—is made by macerating 5 parts of cut senna with 30 parts of boiling water, and exposing it to the heat of a steam-bath for 5 minutes; when cold the liquid is expressed, and 5 parts of sodium and potassium tartrate and 10 parts of manna are dissolved in it; after straining it should weigh 40 parts.

Medical Uses.—The fennel-seed in this preparation lessens the tendency of the senna

to gripe. If the infusion is allowed to macerate too long the tendency is increased. It is a very thorough purgative, and should be given in *doses* of from 2 to 4 fluidounces (Gm. 64–128) every hour, or at longer intervals, until it begins to operate.

INFUSUM SERPENTARIÆ, *Br.*—INFUSION OF SERPENTARY.

Tisane de serpentaire, Fr.; *Schlangenwurzel-Aufguss*, G.

Preparation.—Take of Serpentry-Rhizome, in No. 20 powder, bruised, $\frac{1}{4}$ oz.; Boiling Distilled Water 10 fl. oz. Infuse in a covered vessel for 30 minutes, and strain.—*Br.*

The infusion recognized under the same name by the U. S. P. 1870 was slightly stronger, and contained 15 grains of serpentaria to the fluidounce.

Medical Uses.—This preparation is preferable to the fluid extract and to the tincture of serpentaria. Its uses are fully detailed under SERPENTARIA. *Dose*, 1 or 2 fluidounces (Gm. 32–64) every two or three hours in typhoid conditions.

INFUSUM UVÆ URSI, *Br.*—INFUSION OF BEARBERRY.

Tisane d'uva ursi, Fr.; *Bürentraubenblätter-Aufguss*, G.

Preparation.—Take of Bearberry-Leaves, bruised, $\frac{1}{2}$ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 1 hour, and strain.—*Br.*

The medicinal principles of *uva ursi* are not volatile or decomposed by boiling water; a decoction may therefore be prepared.

Medical Uses.—This is a more convenient form than the decoction for extemporaneous use, and is perhaps sufficiently active, since it is certain that the amount of tannic and gallic acids which can be profitably absorbed from the stomach is not unlimited. *Dose*, 1 or 2 fluidounces (Gm. 32–64).

INFUSUM VALERIANÆ, *Br.*—INFUSION OF VALERIAN.

Tisane de valériane, Fr.; *Baldrian-Aufguss*, G.

Preparation.—Take of Valerian-Rhizome, bruised, $\frac{1}{4}$ ounce; Boiling Distilled Water 10 fluidounces. Infuse in a covered vessel for 1 hour, and strain.—*Br.*

Infusion of valerian, U. S. P. 1870, represented 15 grains of the root in the fluidounce, but made by the present general formula it contains 46 grains.

Medical Uses.—Although partially superseded by the more convenient fluid extract and tinctures, the infusion of valerian is, nevertheless, an efficient preparation, particularly where the medicine must be continuously given. *Dose*, 2 fluidounces (Gm. 64). (For Hypodermic Injections of Apomorphine and of Ergotin, see pp. 1659, 1660.)

INJECTIO MORPHINÆ HYPODERMICA.—*Br.*

Hypodermic injection of morphia, E.; *Injection hypodermique de morphine*, Fr.; *Subcutane Morphineinspritzung*, G.

Preparation.—Take of Hydrochlorate of Morphia 92 grains; Solution of Ammonia, Acetic Acid, Distilled Water, of each a sufficiency. Dissolve the hydrochlorate of morphia in 2 ounces of distilled water, aiding the solution by a gentle heat; then add solution of ammonia, so as to precipitate the morphia and render the liquid slightly alkaline; allow it to cool; collect the precipitate on a filter, wash it with distilled water, and allow it to drain; then transfer the morphia to a small porcelain dish with about an ounce of distilled water, apply a gentle heat, and carefully add acetic acid until the morphia is dissolved and a very slightly acid solution is formed. Add now sufficient distilled water to make the solution measure exactly 2 fluidounces. Filter, and preserve the product in a stoppered bottle excluded from the light.—*Br.*

The object of the above process is the preparation of acetate of morphia in solution of definite strength, so that each fluidrachm shall contain 6 grains of that salt. On keeping, the solution decomposes, acquiring a brown color and slowly separating morphia, the crystals being very long if the solution remain undisturbed. To prevent this decomposition, Prof. C. Johnston (1873) recommended sulphurous acid, 5 drops of which were found by Jennings sufficient to protect a fluidounce. Squibb (1873) observed that $\frac{1}{8}$ per cent. of pure carbolic acid would preserve such solutions, and Limousin (1876) has obtained satisfactory results by using $\frac{1}{8}$ per cent. of salicylic acid.

Medical Uses.—The average hypodermic *dose* of this preparation is from 1 to 6

minims (Gm. 0.06–0.40), equal to from $\frac{1}{12}$ grain to $\frac{1}{2}$ grain (Gm. 0.005–0.03) of the salt.

INULA, U. S.—ELECAMPANE.

Radix Helenii, P. G.; *Radix inula*. *Radix enula*.—*Racine d'année*, *Année commune* (*officinale*), Fr.; *Alantwurzel*, *Helenenwurzel*, G.

The root of *Inula Helenium*, *Linne* (*Corvisartia Helenium*, *Morat*). Woodville, *Med. Bot.*, t. 26; Bentley and Trimen, *Med. Plants*, 150.

Nat. Ord.—Compositæ, Asteroideæ.

Origin.—Elecampane is a native of Central Asia and Southern Siberia, and is found westward to Southern and Central Europe. It is not unfrequently cultivated, and has in

FIG. 160.

Elecampane-root: transverse sections.

many places escaped from gardens and become naturalized. In the United States it grows spontaneously along roadsides and in pastures from New England south to the mountains of North Carolina and westward to Illinois. It has a thick, solid stem 3 to 6 feet (0.9–1.8 M.) high, large radical leaves decurrent on the long petioles, and sessile clasping stem-leaves, all being acute, somewhat toothed, and grayish-hairy on the lower surface. The large flower-heads are terminal, and have a loosely-imbriated involucre, with an outer series of foliaceous ovate bracts; the numerous yellow pistillate

ray-florets are ligulate, linear, and three-toothed, and the yellow disk-florets tubular and five-toothed. The akenes are smooth, pale-brown, four-sided, and crowned with a hairy pappus. The root is collected in the fall of the second or the spring of the third year.

Description.—The root is about 6 inches (15 Cm.) long and 1 or 2 inches (25 or 50 Mm.) thick, divided below into branches 6 to 12 inches (15–30 Cm.) long and $\frac{1}{2}$ to 1 inch (12–25 Mm.) thick, very fleshy, in commerce always sliced either longitudinally or transversely. The longitudinal slices have the bark overlapping; the transverse slices are concave, somewhat radially striate; externally irregularly wrinkled and brownish, internally white when fresh, grayish after drying, of a peculiar aromatic odor and an aromatic, bitterish, and pungent taste. The root is hygroscopic and flexible in damp weather, but when dry breaks with a short fracture. The bark is $\frac{1}{4}$ inch (3 Mm.) and more thick, the inner portion radiate near the cambium-line; the medullium has small fibro-vascular bundles and broad medullary rays, and all parts of the root are dotted with shining yellowish-brown resin-cells.

Constituents.—Elecampane contains a little *volatile oil*, some *acid resin*, a *bitter principle* not known as yet in the isolated state, *waxy matter*, *inulin*, etc. On investigating the body formerly known as helenin and elecampane camphor, which crystallizes from the concentrated tincture mixed with water, Kallen (1873) isolated *helenin*, C_6H_8O , which is insipid, almost insoluble in water, crystallizes in needles, fuses at $110^\circ C.$ ($230^\circ F.$), and is by nitric acid converted into oxalic acid and a resinous body. On distilling the root with steam, Kallen (1876) obtained *inula camphor* or *alant camphor*, $C_{10}H_{16}O$, and *inulol* or *alantol*, $C_{15}H_{20}O_2$. The first of these forms colorless needles of a faint camphoraceous odor and taste, melts at $66^\circ C.$ ($150.8^\circ F.$), and is sublimable and very slightly soluble in water. Alantol is a yellowish liquid having the odor of peppermint and an aromatic taste, boiling near $200^\circ C.$ ($392^\circ F.$), and yielding crystallizable alantol or inulic acid, $C_{15}H_{22}O_3$. *Inulin*, $C_{12}H_{20}O_{10}$, is contained in the subterraneous parts of Compositæ, and is obtained by forcibly expressing the grated juicy roots, when a portion will deposit on standing, and the remainder may be precipitated by alcohol. Kiliani (1881) recommends boiling the roots with water containing sodium carbonate: the liquid is cooled by a freezing mixture, and the precipitate repeatedly dissolved in hot water and reprecipitated by cooling. The autumn roots contain the largest percentage (elecampane 44 per cent.) of inulin, which by the following spring is to a considerable extent changed into mucilage, sugar, and levulin, and in some cases to glucosides. Inulin is a fine white powder, tasteless and odorless, insoluble in alcohol, slightly soluble in cold water, more so in hot water, and then partly altered, but mostly reprecipitated on cooling; on the slow evaporation of its aqueous solution it may be obtained in crystalline spheres, and by hydration it is converted into gum-like and horny modifications. It appears to be the anhydride of levulose, its formula being $(C_6H_{10}O_5)_{10}H_2O$, but it does not reduce Fehling's solution. Heated with water in sealed tubes, it yields levulose; with hot baryta-water

lactic acid is formed; diluted nitric acid oxidizes it to formic, oxalic, racemic, glycollic, and probably glyoxylic acids. Inulin differs from starch by the absence of concentric layers, does not yield a jelly with water, and it is colored yellow (not blue) by iodine. (Two monographs on inulin were published in 1870—one by Prof. Dragendorff, the other by Dr. K. Prantl.)

Allied Drug.—*RADIX CARLINÆ*.—Carline thistle, *E.*: Chardon doré, Carline, *Fr.*; Eberwurzel, *G.*—*Carlina acaulis*, *Linneé* (Nat. Ord. Compositæ, Cynaræa), is a perennial plant, a native of Middle Europe. The root is long, fleshy, nearly an inch (25 Mm.) thick, and with few branches. It is usually cut lengthwise, is deeply wrinkled, and gray-brown externally, has a rather thin light-brown bark and a grayish fleshy medullium, which, like the inner bark, is radiately marked by broad medullary rays. Rather large brown-red resin cells are found in all parts of the parenchyma. It has a penetrating, unpleasant odor and a sweetish, burning, and bitter taste; its principal constituents are a little resin and a volatile oil, to which the odor and taste are due.

Pharmaceutical Preparation.—*EXTRACTUM HELENII*, *P. G.*—Extract of elecampane, *E.*—It is made by displacing the powdered root with cold distilled water (*F. Cod.*), or, preferably, by exhausting the ground root with a mixture of 2 parts of alcohol and 3 parts of water (*P. G.*).

Medical Action and Uses.—*Inula* was one of the most famous of ancient medicines, and continued in vogue until very recent times. It owed this reputation to its stimulant qualities. Even in the Hippocratic writings it is stated to be a stimulant of the brain, the stomach, the kidneys, and the uterus—qualities which continued to be ascribed to it—as well as to exert a rubefacient action upon the skin. It had a special reputation in all pulmonary affections and as a topical application in sciatica, gout, gravel, facial neuralgia, etc. One of its chief constituents, inulin, is probably quite negative, and whatever virtues the plant possesses must be due to the elecampane camphor, which it contains in small proportion, a very minute quantity of volatile oil, and the bitter extractive, which it holds in as large a proportion as of inulin. These elements are apparently too insignificant to justify the ancient repute of elecampane. It continues to be used as a domestic remedy, rather than by physicians, in the treatment of chronic *bronchitis*, *dyspepsia*, *vesical catarrh*, *amenorrhœa*, and other menstrual disorders, and internally in chronic eruptions of the skin. Korab claims for helenin a power of destroying bacilli, and especially those of tubercle (*Bull. de thérap.*, ciii. 271). The practical value of the alleged fact remains to be seen. It is also preserved as a candy, like calamus, and is used to flavor the alcoholic beverage *absinthe*. Its retention in the United States Pharmacopœia seems quite superfluous. Elecampane is generally administered in a decoction prepared by boiling half an ounce of the root in a pint of water (Gm. 16 in (Gm. 500)), and which may be given in the *dose* of 2 or more fluidounces (Gm. 64). Some German writers direct from 5 to 15 parts of elecampane to 100 parts of hot water.

CARLINA ACAULIS had formerly a reputation not inferior to that of *inula* for very similar virtues. It was held to be powerfully diaphoretic or diuretic, according to the manner of its administration, and in large doses purgative. It was prescribed in *typhoid states* of acute diseases, in *amenorrhœa*, to overcome sexual *impotence*, and relieve local *paralysis*, especially of the tongue. It was administered in powder in *doses* of from 10 to 20 grains (Gm. 0.60–1.30), in decoction, etc.

IODI BROMIDUM.—BROMIDE OF IODINE.

Bromure d'iode, *Fr.*; *Jodbromid*, *G.*

Formula IBr_2 . Molecular weight 527.

Preparation.—20 parts of iodine are dissolved in 63 parts of bromine, and the solution heated for some time in a large flask to about 60° C. (140° F.), until it yields a clear solution with 6 or 8 parts of water.

Properties.—Pentabromide of iodine is a dark reddish-brown liquid, resembling bromine in appearance and sensible properties, but yielding a perfectly transparent brown-red solution with less than 6 parts of water. In the presence of a small quantity of water and at a low temperature the hydrate crystallizes in brown-yellow needles or prisms, melting again at 4° C. (39.2° F.), with separation of the water. A solution containing 15 per cent. of the bromide is found in commerce. When the compound is kept for some time at or above 63° C. (145.4° F.), the boiling-point of bromine, a portion of the latter distills off, and monobromide of iodine, IBr , is left as a dark-brown sublimable crystalline mass.

Terbromide of iodine is also prepared, and requires for 20 parts of iodine 37.8 parts of bromine.

Medical Uses.—A solution of 2 drops in a fluidounce of mucilage (Gm. 0.13 in Gm. 32) has been applied in *diphtheria*.

IODOFORMUM, *U. S., Br., F. Cod.*—**IODOFORM.**

Iodoformium, P. G.—*Iodoforme*, Fr.; *Jodoform*, G.

Formula CHI_3 . Molecular weight 392.8.

Iodoform should be kept in well-stopped bottles in a cool place.

Origin.—Iodoform was discovered by Serullas in 1822, and its composition was determined by Dumas in 1834. It is formed by the action of iodine in the presence of fixed alkalis or alkali carbonates upon alcohol, acetic and other easily-saponifiable ethers, aldehyd, acetone, amylene, butyl, capryl, and propyl alcohols, kinic, meconic, and lactic acids, oil of turpentine, and some other compounds (Lieben, 1870). Millon (1846) ascertained that it is also produced, to a limited extent, by the action of the same agents, aided by heat, upon aqueous solutions of sugars, dextrin, and gum, and upon alkaline solutions of albumen, fibrin, casein, and other proteids. Pure ethyl ether, ethyl iodide, and allied compounds, methyl and amyl alcohol, chloral, chloroform, the fruit acids, lower fatty acids, various aromatic acids, glycerin, and other compounds, according to Lieben, do not yield iodoform under the conditions mentioned above.

Preparation.—Wilder (1875) recommends Bouchardat's process as an easy one, and Filhol's as one giving a large yield. By following the former, 100 parts iodine, 100 potassium bicarbonate, 1200 water, and 250 alcohol are mixed in a flask with a long neck and slowly heated to between 60° and 80° C. (140° and 176° F.) until the color has disappeared, when 25, 20, and 10 parts of iodine are to be added, waiting after each addition until the iodine color has disappeared, and adding at the close, if necessary, a little potassa: after setting aside for 24 hours the crystals are collected upon a filter. About one-third of the iodine is recovered as iodoform, the remainder appearing in the mother-liquor chiefly as iodide of potassium, and may be obtained by supersaturating with sulphuric, and then adding a little nitric, acid.

In Filhol's process this iodine is utilized by liberating it by means of chlorine and converting it into iodoform. The proportions recommended are 2 parts of crystallized sodium carbonate, 10 of water, and 1 of alcohol, warmed as before; 1 part of iodine is added in small portions, and after cooling the crystals are collected. The filtrate is again warmed, 2 parts of sodium carbonate are added, and a rapid current of chlorine gas is passed through the liquid as long as iodoform is separated, which is again collected, while the filtrate may be made to yield a little more iodoform by repeating the treatment. As much as 72 per cent. of crystals may thus be obtained.

Rother (1873) recommended acidulating the mother-liquor with hydrochloric acid, adding some potassium bichromate to generate chlorine, then potassium carbonate to render the liquid alkaline, and some iodine and alcohol, and finally warming the mixture. The process will thus be continuous until the accumulation of the salts becomes too great. More recently (1882) he recommended bromine in place of chlorine.

The production of iodoform may be explained by the simultaneous formation of potassium iodide, water, and carbonic acid, as follows: $\text{C}_2\text{H}_6\text{O} + 4\text{I}_2 + 2\text{KHCO}_3$ yields $2\text{CHI}_3 + 2\text{KI} + 3\text{H}_2\text{O} + 2\text{CO}_2$. The reaction, however, is never so simple, formate of potassium being perhaps always one of the products, in which case the reaction, according to Liebig, is thus explained: $\text{C}_2\text{H}_6\text{O} + 4\text{I}_2 + 6\text{KHCO}_3$ yields $\text{CHI}_3 + 5\text{KI} + \text{KCHO}_2 + 5\text{H}_2\text{O} + 6\text{CO}_2$. At the same time other reactions take place—one resulting in the formation of acetic ether, another in the production of ethyl iodide and hydriodic acid; and from great variations of the yield observed it is evident that the result is greatly influenced by the relative proportion of the material and the temperature.

Properties.—Iodoform is in small, lemon-yellow, scale-like, hexagonal crystals, which have a pearly lustre, are somewhat fatty to the touch, and have a strong saffron-like odor and a peculiar sweetish and unpleasantly iodine-like taste. It is nearly insoluble in water, but by heating it with water for about 30 minutes to between 80° and 90° C. (176° and 194° F.) a permanent yellow solution is obtained, which, according to Schadeewald (1882), contains between .5 and .7 per cent. of iodine. Iodoform dissolves in 80 parts (*U. S.*, 50 parts (*P. G.*), of alcohol at 15° C. (59° F.), in 12 parts (*U. S.*), about 10 parts (*P. G.*), of boiling alcohol, in 5.2 parts (*U. S.*, *P. G.*) of ether, and, according to Vulpius (1881), in 100 parts of petroleum benzin, in 67 parts of benzol, in 25 parts of oil of turpentine,

in 14.3 parts of oil of lavender, in 12.5 parts of oil of cloves, in 11 parts of oil of fennel, lemon, or rosemary, in 7 parts of oil of cinnamon, and in 6 parts of oil of caraway; it is readily soluble in chloroform, carbon bisulphide, and fixed oils; the solutions have a neutral reaction to test-paper, but when exposed to sunlight liberate iodine. Iodoform has the spec. grav. 2.0, volatilizes slowly on exposure at ordinary temperatures, fuses at about 115° C. (239° F.) to a brown liquid, and sublimes partly unaltered, but at a higher heat is mostly decomposed into iodine and hydriodic acid, with a residue of glossy charcoal, which finally burns without leaving any residue. Heated with water, it volatilizes with the vapors without decomposition; but when boiled with potassa solution a portion of it is decomposed, yielding formate and iodide of potassium, and when distilled with alcoholic solution of potassa an oily liquid of an ethereal odor and containing iodine is obtained in the distillate; both the aqueous and alcoholic solutions thus obtained on the addition of nitric acid liberate iodine, recognizable by the blue color produced with starch-paste.

The odor of iodoform in mixtures and ointments is unpleasant, and may be disguised by the addition to 1 ounce of from 3 to 5 drops of oil of peppermint; Peru balsam, coumarin, the oils of fennel, anise, and others, have also been recommended. The odor adheres persistently to the vessels in which preparations of iodoform have been made, and may be removed by solution of potassa, aided by alcohol or boiling water.

Impurities are not likely to be present; the physical properties, and particularly its odor, behavior to solvents, neutral reaction, and complete volatility, determine the absence of impurities which might result from the process of manufacture. Fixed impurities would be left behind on heating a portion upon platinum-foil until the charcoal has been consumed. "Distilled water shaken with iodoform, and filtered, should give no precipitate with test solution of nitrate of silver (absence of iodide and iodate), *U. S.*, *P. G.*, or with nitrate of barium (absence of carbonate, iodate, and sulphate)." — *P. G.*

Off. Prep.—Unguentum iodoformi, *U. S.* (See page 1574.)

SUPPOSITORIA IODOFORMI, *Br.*, contain iodoform 3 grains, cacao butter 12 grains.

COLLODIUM IODOFORMI.—Iodoform collodium.—Iodoform, balsam of Peru, powdered soap, of each 5 parts; collodion 85 parts; dissolve (James).

Physiological Action.—The experiments of Mikulicz (*Wiener Klinik.*, Jan. 1882) prove that, except when used in large proportion, iodoform has but a slight and transient power to prevent putrefactive fermentation, and that it is entirely wanting in a speedy and energetic disinfecting power, and especially can never be available for purifying the hands of the surgeon and the instruments, etc. used in operating. Given to animals, iodoform occasions a certain degree of hebetude or somnolency, muscular debility, staggering, and anæsthesia, and in large doses muscular rigidity and opisthotonos. 30 grains were fatal to a guinea-pig, 45 grains to a rabbit, and 60 grains to a dog of medium size. The experiments of Binz and of Högyes on such animals do not furnish any instance of convulsive attacks produced by this compound, but show that the reflex excitability is but feebly maintained throughout the deepest sleep, and is replaced by paralysis and a marked fall of temperature on the approach of death. On dissection fatty degeneration is found in the liver, kidneys, heart, and the muscles generally. In the lower lobes of the lungs hæmorrhagic infarcta exist. Applied in substance upon or under the skin, in the digestive canal, or on serous membranes, iodoform unites with the fat and is decomposed, with a liberation of iodine, which combines with the albumen, forming an albuminate that is absorbed, usually without leaving any lesion of tissue behind. Ultimately, the iodine is excreted, chiefly with the urine, in combinations which are soluble in water. After death no evidence of irritation is found in the stomach, whose lining membrane, on the contrary, is rather pale. But all the organs exhale the characteristic smell of the medicine (*Archiv. f. exper. Pathol.*, xiii. 113). Von Hoffer states that in animals, and also in syphilitic patients, the continued use of iodoform diminishes the red corpuscles of the blood and produces loss of weight.

In man doses of from 2 to 5 grains occasion no signs of a caustic operation, but 7 or 8 grains have caused a decline of the pulse-rate from 72 to 60. Applied to the sound skin and mucous membranes and to ulcers, it is not in the least irritating; on the contrary, it appears to allay all local painful sensations in them, and it even blunts common sensibility. Thus it may render the anus so insensible that the passage of the fecal mass will not be perceived. Sometimes the application of iodoform has excited a severe eczematous eruption (*Boston Med. and Surg. Jour.*, March, 1882, p. 250). It appears to be eliminated with the breath and all the secretions, and very speedily after its administration. Many cases of poisoning by this preparation have been recorded. A woman affected with syphilis had taken in the course of 4 months about 42 Gm. (3j, 5iij) of iodoform in pills containing each 1 Gm. (gr. ʒ). She was suddenly attacked with faintness, vertigo, and

double vision; within 2 days she sank into a deep sleep which lasted for 36 hours, and was followed by excitement, violent headache, and confused speech, succeeded by debility and a tottering gait, after which the vertigo, headache, and diplopia recurred. These effects lasted for a fortnight. In the case of another woman the toxical phenomena occurred at the end of the first week, and when no more than 5 Gm. (75 grains) of iodoform had been taken. She slept continuously for 5 days, after which debility and vertigo were experienced for several weeks (Oberländer).

In 1882, according to Dentu, there had already been published eleven cases of death following the use of iodoform as a surgical dressing, and many others had been reported in which dangerous or disagreeable phenomena were observed. The principal symptoms were lassitude, faintness, headache, irritability or depression of mind, rapid pulse, maniacal delirium, drowsiness or coma, rigid muscular flexion, local paralysis (including paralysis of the sphincters), aphonia, and inequality of the pupils, and in some cases a suicidal tendency. Very generally there was a rapid increase of the pulse-rate to 140, and even 180, and a corresponding rise of temperature to 102°–104° F., but this rise was followed by a rapid fall. A taste of iodoform in the mouth was complained of by many patients. The appetite failed; vomiting was usual, and was persistent and incoercible, the rejected liquid consisting of greenish mucus and water. The lesions found after death were fatty degeneration of the heart, kidneys, and liver. Iodoform intoxication is less apt to occur in children than in adults. Somnolence has been caused apparently by the inhalation of a drachm of powdered iodoform scattered on the patient's bed. Albert saw swelling of the parotids besides the delirium above mentioned. The plugging of a wound with the preparation has been followed by fatal collapse. According to Schede, "There is an idiosyncrasy against iodoform which makes it a dangerous poison for some persons, the more so that there are no indications to suggest special care, and that in many cases the poisonous action seems to be cumulative, so that its symptoms make their appearance suddenly and with great severity, and then even the instant withdrawal of the drug does not avert the fatal issue." (Compare *Phila. Med. Times*, xii. 560; *Amer. Jour. of Med. Sci.*, April, 1882, p. 545; *ib.*, Oct. 1882, pp. 577, 579, 629; Jan. 1883, p. 301; *Med. News*, xli. 240; *Med. Record*, xxi. 324; *Practitioner*, xxiii. 129; *Amer. Jour. of Phar.*, Feb. 1883, p. 104; *Centralblatt f. d. ges. Therapie*, i. 52; *Jour. Amer. Med. Assoc.*, i. 307; *Edinb. Med. Jour.*, xxix. 674.)

Medical Uses.—After having been used in 1846 by Bouchardat in cases of lymphatic glandular swelling, goitre, and amenorrhœa, it was employed ten years later by Maitre for similar affections, syphilis, diseases of the skin, and of the bladder, etc. This physician drew attention to its anodyne virtues, and administered it internally to the extent of 40 or 50 grains daily. Its value was more fully declared in 1862 by Righini, who demonstrated the presence of iodine in all the secretions after the administration of iodoform, and in the urine after even its external application. He stated, however, that, unlike iodine, it did not cause emaciation or stimulate the glands or act as a local irritant. He enlarged somewhat the sphere of its therapeutical uses. Its most important agency was first announced by Von Mosetig-Moorhof in 1879 to be that of a dressing for surgical wounds, and for this purpose it has been widely and successfully used, especially in Germany. Its anodyne quality was conspicuously displayed in the treatment of cancer of the uterus, breast, and other parts, for the progress of the local disease was rendered slower and the exhaustion of the patient's strength was retarded. Indeed, not a few tumors (canceroid), supposed to be cancers, were entirely cured under this treatment. Its special value as a dressing in cases of cancer consists in its relieving the pain and correcting the offensive smell of the discharges. But it also retards the progress of ulceration. Simple ulcers of the cervix uteri are most efficiently treated by its means, although some persons associate with it a carbolic acid lotion. No agent is more successful in promoting the removal of exudations in *metritis*, *parametritis*, and *perimetritis*, as well as in relieving the pain of these affections. It may be applied directly by means of a tampon or introduced into the rectum in a suppository. The absorption of the medicine in these cases is demonstrated by the taste in the mouth of which the patients complain. Moleschott praises highly a mixture of 1 part of iodoform and 15 parts of flexible collodion, applied night and morning with a brush, as a discutient of *swollen glands* in the neck and elsewhere, as well as of *effusions* in the *pleura*, *pericardium*, *peritoneum*, and even the *arachnoid*, and as a curative application to *chronically-inflamed joints*. He ascribes the cure of several cases of *tubercular meningitis* to the use of this compound, which was painted three or four times daily over the nape of the neck, the mastoid processes, the temples, and the forehead. Venereal and all other chronic *ulcers* are most favorably influenced by iodo-

form, the more so in proportion as they are irritable and painful. "Under its use healthy sores heal rapidly, creeping sores generally cease to spread, and sluggish ones take on healthy action" (Hill). Another declares its effects to be almost magical (*Practitioner*, xxii. 321). Mr. Miller says of his treatment of "chancreoids," "I simply dust them with iodoform powder and keep them dry, and they invariably heal up in a few days" (*Edinb. Med. Jour.*, xxviii. 390). This surgeon especially lauds the virtues of the application to venereal sores of the female genitals; he also uses it for buboes after evacuation and for syphilitic ulcers of the mouth, nose, etc. In these encomiums almost all syphilographers unite. But, as a recent writer adds, iodoform "will not retard the growth of a large, indurated, infecting chancre, and will not arrest phagedena; it will not remove venereal warts nor materially affect an inflamed gland" (*Med. News*, xli. 98). It is alleged to exert a favorable influence upon the later constitutional symptoms of *syphilis* when given internally in doses of from $\frac{1}{4}$ to $\frac{1}{2}$ grain several times a day, and has also been administered hypodermically, suspended in glycerin, for a similar purpose. A solution of 1 part of iodoform in 6 or 7 of ether is considered by some surgeons preferable to the former agent alone, since it acts in smaller quantity and also as a protective to the sore. Whitehead and others also prefer an ethereal solution of iodoform to the powdered drug, or a solution of 1 part of iodoform in 2 parts of ether and 7 parts of collodion. Carded cotton thoroughly impregnated with iodoform has also been found very useful for applying the medicine to the nostrils, vagina, and rectum. In the simple as well as in the syphilitic form of *ozæna* this treatment has been found successful, and an ointment of iodoform prepared with vaseline has been used with equally good results. The same statement is true regarding syphilitic ulcers of the *pharynx*, to which the ethereal solution or the powder has been applied, or which have been treated with gelatin lozenges, each containing 1 or 2 grains of iodoform and allowed to dissolve slowly in the mouth. When the liquid preparations have been used for the purposes under notice it has been recommended to administer at the same time pills, each containing $1\frac{1}{2}$ grains of iodoform, three times a day in the beginning, the dose being gradually increased until 8 or 10 pills are taken in 24 hours. This combined local and general treatment is strongly recommended in cases of syphilitic fissured *ulcer of the tongue*. The application of iodoform as a dressing for open *buboes*, and especially for such as have indurated walls and sinuses, has been singularly efficacious, as it also has in the treatment of *chronic otorrhæa*. In all of the cases now named it deodorizes, while it tends to heal, the ulcerated surfaces. It is reputed to be an efficient application to *ringworm of the scalp*, and in the treatment of *purulent ophthalmia*, *granular or ulcerated eyelids*, *ciliary blepharitis*, *pannus*, and *phlyctenæ* and *ulcers of the cornea*. In these affections of the eyeball it is recommended to apply finely-powdered iodoform by means of a camel's-hair brush, and to use for the eyelids an ointment made with 1 part of iodoform to 4 parts, and for the eyeball 1 part to 10 or 15 parts, of vaseline. It allays the pain and promotes the healing of blistered surfaces and of ulcers left by *burns*. In some cases of ulcerated fissure of the *anus* it has proved a very useful palliative, as well as in certain *hæmorrhoidal* affections attended with pain in defecation. In both of these affections it acts by promoting a more healthy nutrition, while it prevents the irritation and pain which tend to perpetuate them. Iodoform suppositories used in these affections are apt to cause general toxic symptoms. Riehl has successfully treated *lupus vulgaris* with iodoform after removing the cuticle with caustic potassa. The latter agent occasions pain which the subsequent application of the iodoform neutralizes, while it causes a gradual shrivelling and disappearance of the morbid growth (*Boston Med. and Surg. Jour.*, May, 1882, p. 415). It appears to act in a similar manner upon various local inflammatory swellings of the *lymphatic glands* and the *testes* and to diminish the size of *goitrous* tumors. In *diseases of the skin* it seems to have been found more useful in dry and chronic affections than in others; thus, in *psoriasis* and *prurigo*, rather than in *eczema*. It has, however, been declared by Squire to be a very convenient and efficient remedy for *impetigo laræalis* (*British Med. Jour.*, May 14, 1881); and Frazer found it useful both in local *eczema* and *impetigo* and in *prurigo decalrans* (*Practitioner*, xxvii. 280); and it has been applied in an ointment or liniment to prevent pitting in *small-pox*. In *chronic nasal catarrh* powdered iodoform, diluted with a neutral powder, has been successful not only in deodorizing the discharge, but also in arresting it. A similar application, or one of iodoform dissolved in ether, has been found salutary in specific and other *ulcers of the throat, vagina*, etc.; and in chronic suppuration of the middle ear, but more especially of the internal *auditory canal*, iodoform excels all other applications in diminishing the discharge, correcting its fetor, and restoring the part to its normal condition. Some claims have been made for this medicine as a topical remedy

in *diphtheria*, but they rest upon very inadequate grounds. The *gangrenous vulvitis* which is so common under certain conditions of constitution and recent sickness in hospital practice is more successfully controlled by powdered iodoform than by any other agent. According to Parrot (*Bull. de thér.*, c. 382), nothing so easily and promptly cures that aphthous form of *vulvitis* which attacks feeble and ill-fed children. In other forms of hospital *gangrene* it is efficacious. It is one of the best palliatives of *pruritus pudendi* when applied in an ointment containing about 20 grains to the ounce (Gm. 1.20 in Gm. 30). The anodyne virtues of iodoform displayed in these affections, as well as in various other painful disorders of the rectum, bladder, and uterus, the mouth and the nasal passages, are also exhibited in some internal disorders, and particularly in those of the stomach. *Gastralgia*, alone or associated with simple *gastric ulcer*, is relieved by it, and sometimes permanently cured. In cases of vaginal hyperæsthesia and *vaginismus* its action is favorably exhibited, especially when these conditions depend upon a lesion of the mucous membrane. In the absence of the latter belladonna may be usefully associated with iodoform. External *neuralgiæ* have, it is said, been cured by iodoform, but as in every case it was associated with iron, the cure was very probably due to the latter medicine. But there can be no doubt of its palliative anodyne action in these affections. According to Moleschott, it has often relieved the most intense pains and other symptoms of *gouty* inflammation within 24 hours after painting the affected part with the solution of iodoform in collodion. An ointment made with 1 part of iodoform and 4 parts of vaseline is said to have promptly reduced the pain and swelling in acute *orchitis* (*Med. Record*, xix. 463). Iodoform has also been recommended to relieve the pain of a *carious tooth*, but it was used along with carbolic acid, oil of peppermint, or other anæsthetic, to which, probably, the relief was mainly due. Owing to the use by German writers of the word "tubercle" in its generic sense, it has been supposed that iodoform was claimed to be a remedy for pulmonary tubercular phthisis; no reasonable physician has preferred so preposterous a claim. Some, however, allege that the medicine is a palliative of the cough, expectoration, fever, and sweating, in this disease, and attribute this favorable action to its elimination in part through the lungs.

The application of iodoform as a dressing for surgical and other wounds, which was introduced by Mosetig-Moorhof in 1879, became very general in 1880, and especially in Germany. It is claimed to be absolutely unirritating; wounds are said to be stimulated by it even less than by carbolic acid lotions, and the granulating process is thought by Mikuliez (*Wiener Klinik*, Jan. 1882) to be rather retarded than quickened by it. It has a remarkable anæsthetic action, and when kept applied to wounds is a disinfectant which has the advantage of being altogether unirritating. According to the surgeon just named, it is neither as prompt nor as energetic as some other antiseptics, and is quite unsuited for disinfecting the surgeon's hands, instruments, etc. Owing to its mild action, it is recommended as a permanent dressing for recent wounds, and especially for such as are attended with a loss of substance. It is said to be less eligible for granulating wounds. In penetrating wounds and deep cavities the whole interior surface should be coated with iodoform powder, but in recent wounds which are to be healed by the first intention it is, according to this authority, superfluous, if not injurious, to apply the powder to the raw surface, but the part should be dressed with iodoform gauze. In contused, complicated, and other analogous wounds due drainage precautions should be observed. An iodoform gauze dressing is also recommended in all operations involving the peritoneum, intestine, etc., and in those interesting the nasal cavities, the mouth, pharynx, rectum, vagina, etc. A great value is claimed for iodoform gauze in some of these cases—e. g. in excision of the tongue for cancer of that organ, as reported by Billroth (*Amer. Jour. of Med. Sci.*, April, 1882, p. 567). Its advantages are very conspicuous in the treatment of open cancer, *septic* and *gangrenous wounds*, and *ulcers*, in *paronychia* and *paronychia*, in *boils* and *carbuncles* after incision, and in the lesions connected with *scrofula*, *lupus*, and *sypilis*.

At the risk of some repetition, a brief summary may here be given of the conclusions of Mosetig-Moorhof, the most enthusiastic promoter of the surgical application of iodoform (1882): It is a specific against the formation of exuberant granulations, and represses them when they already exist, transforming them into a firm and healthy tissue. To effect this purpose it is necessary to scrape the indolent growth, so as to expose a raw surface. After this operation and the dressing the discharge ceases to be purulent. Iodoform is the most certain antiseptic of every description of wound, and in a moderate amount is not hurtful to the system, although it is absorbed and is found excreted with the urine. Its primary action is, indeed, anæsthetic, but secondarily it quickens granu-

lation and absolutely prevents all septic processes in wounds. Under its use the healing process is apyretic, or, if at first the evening temperature is raised, it does not present the characters of septic fever. Introduced into a wound, it does not prevent union by the first intention. Still, with the iodoform dressing, as with all others, provision must be made for the escape of the secretions. Their discharge does not impair the antiseptic quality of the application, but the rise of temperature that attends their accumulation demands a renewal of the dressing, which also permits an inspection of the wound. If after a few days traumatic fever does not arise, a fresh dressing, although desirable for the sake of cleanliness, is not absolutely necessary. Under this method traumatic erysipelas is very rare. Iodoform as an antiseptic renders other antiseptics unnecessary. Besides it, only pure water is required. Perfect cleanliness of the hands and instruments that touch the wound is essential. Iodoform is the cheapest, surest, and most permanent of all antiseptic dressings. The materials are easy to manage. Iodoform powder and gauze may be preserved for years without the slightest loss of activity. They may be applied antiseptically to the buccal cavity and in or near the rectum and bladder.

The judgments now given are substantially the same as those of all the leading surgeons of Germany. (Compare *Centralblatt f. d. gesammte Therapie*, i. 49.) The results obtained by Prof. Boeckel of Strassburg are scarcely less remarkable than those now recorded (*Bull. de therap.*, cii. 265, 321). In England most of the reports of the German surgeons have been confirmed (*Med. Record*, xxi. 400), and in this country, although the published accounts of iodoform in surgery are of the same character, they are less numerous than might have been expected (*ibid.*, xxi. 309). It is highly probable that the offensive smell of the preparation is the chief cause of its comparatively limited use outside of Germany. This is the more remarkable in view of the language of hyperbole which its German promoters adopt. Von Mosetig-Moorhof in his enthusiasm exclaims: "The hymn of praise that I have sung to iodoform is not pitched upon too high a key. The most eminent German surgeons join in the chorus that soon will echo around the world. Only let not impossibilities be expected from this agent; it cannot work miracles."

Administration.—The dose of iodoform is from 1 to 3 grains (Gm. 0.06–0.20) three times a day, in pill. It may be applied in a very fine powder, the part having been thoroughly dried, or in ointments, liniments, or suppositories, each application containing about 2 grains (Gm. 0.10) of iodoform. For some of these purposes it may be dissolved in alcohol, chloroform, ether, oil, glycerin, or vaseline. It may be used for insufflation or sprinkling, mixed with lycopodium, powdered sugar, or starch. As already described, it has been incorporated with gelatin to form pastilles. The following formulæ have been recommended: *R.* Iodoform $\mathfrak{z}$ j– $\mathfrak{z}$ iss; glycerin $\mathfrak{f}\mathfrak{z}$ xij; alcohol $\mathfrak{f}\mathfrak{z}$ iv.—*M.* *R.* Iodoform gr. xxx; alcohol q. s.; lard $\mathfrak{z}$ j.—*M.* The following may be used for making suppositories: *R.* Iodoform Gm. 2.50 (gr. xxxviii); cocoa-butter Gm. 40 ($\mathfrak{z}$ j, $\mathfrak{z}$ ij); yellow wax Gm. 5 (gr. lxxv). Mix at a gentle heat, and make ten suppositories. Cylinders made with cocoa-butter, mucilage, and glycerin or gelatin are used in the treatment of sinuses and other deep and narrow cavities. A solution for topical application may be prepared by dissolving 1 Gm. (15 gr.) of crystallized iodoform in 4 Gm. (60 gr.) of sulphuric ether (60° Baumé).

A 20 per cent. solution of iodoform in ether has been used hypodermically. A 25 per cent. solution in olive oil and a 10 per cent. solution in glycerin have been injected into the *nasal* and other natural *cavities*, into cold *abscesses* after their evacuation, etc. Iodoform ointments generally contain from 5 to 10 per cent. of iodoform. Elastic collodion, containing from 6 to 10 per cent of iodoform, is a very useful application to inflammatory *swellings* of various kinds, enlarged lymphatic *glands*, the tender points in *neuralgia*, etc.

The smell of iodoform is intolerable to many and offensive to all, and the ingenuity of surgeons and pharmacists has been taxed to devise methods of neutralizing or concealing it. The latter object has been sought by the use of fragrant substances, such as musk and the oils of bergamot, peppermint, lavender, cinnamon, thyme, and eucalyptus. Oil of southernwood (*Artemisia abrotanum*) has been proposed for the same purpose. The following formula has been employed: Iodoform $\mathfrak{z}$ ij; oil of eucalyptus $\mathfrak{m}\mathfrak{xv}$; oils of verbena, mirbane, lavender, and lemon, of each $\mathfrak{m}\mathfrak{v}$ (Arthur). When the powdered drug is kept in a jar with several Tonqua beans its odor is greatly diminished. An ointment recommended by Auspitz contains iodoform and carbolic acid, of each 2 parts; lard 7 or 8 parts. Lindemann claims that 2 parts of balsam of Peru to 1 of iodoform completely mask the smell of the latter. This mixture can be conveniently

made up in an ointment with vaseline. Tannin is also stated to lessen the smell of iodoform.

IODUM, U. S., Br., P. G.—IODINE.

Iodinium, U. S. 1870.—*Iode*, Fr.; *Jod*, G.

Symbol I. Atomicity univalent. Atomic weight 126.6.

A non-metallic element, obtained principally from the ashes of sea-weeds and from the mother-liquor of Chilian sodium nitrate. Iodine should be preserved in glass-stoppered bottles in a cool place.

Origin.—Iodine was discovered in 1811 by Courtois in the ash of sea-weeds, and was soon afterward thoroughly investigated by Gay-Lussac; also by Davy, Soubeiran, and others. It is very widely distributed in nature, but is usually met with in small, and even quite minute, quantity, almost invariably in combination. It is found in some minerals combined with mercury, silver, lead, and other metals; in Chili saltpetre, principally as sodium iodate; in many mineral spring-waters, in sea-water, in coal, and in many plants and animals living in sea-water or near the sea-coast. It is often a constituent of the atmosphere in minute quantities, and occasionally of the ashes of some plants growing inland. During the fiscal year 1866–67 the United States imported 10,701 pounds of crude and 889 pounds of resublimed iodine; in 1878 the amount was 73,687 pounds, and in 1881 182,863 pounds, of the crude article.

Preparation.—*Kelp* is the ash left on the burning of sea-weeds. The weeds are first dried, and then charred or burned at as low a temperature as possible, to avoid loss of iodine. The ash is exhausted with hot water, and the solution concentrated and cooled to remove by crystallization potassium chloride and sodium carbonate and sulphate. More of the latter salt will crystallize after the addition of some sulphuric acid, whereby the sulphides and hyposulphites present are decomposed. To the mother-liquor, heated in lead retorts to a temperature a little over 60° C. (140° F.), binoxide of manganese is added in small quantities, when iodine will distil over, and is collected in glass receivers, several of which are connected with each other. The liberation of iodine from the sodium iodide of the liquor is explained by the following equation: $2\text{NaI} + 3\text{H}_2\text{SO}_4 + \text{MnO}_2 = \text{I}_2 + 2\text{NaHSO}_4 + \text{MnSO}_4 + 2\text{H}_2\text{O}$, acid sodium sulphate and manganium sulphate being formed at the same time. The mother-liquor obtained on the purification of Chili saltpetre contains sodium iodate and iodide; from the latter the iodine is separated by chlorine gas; from the former, by sulphurous, or preferably by nitrous, acid, in which case sodium sulphate or nitrate is produced.

Purification.—In the crude state iodine is chiefly contaminated with water, but it sometimes contains also cyanogen iodide, and occasionally iodine chloride, ICl . Purification is effected by drying the product as much as possible by mechanical means, and then subliming it carefully, so that the more volatile compounds named may first sublime; afterward the heat is raised and the receiver changed. The product is the *resublimed iodine* of commerce.

Properties.—Iodine is in flat, scale-like rhombic crystals of a grayish-black or bluish-black color and a bright metallic lustre, in thin splinters transparent with a red color. It is soft and friable, and has a peculiar odor, suggestive of chlorine, and a very caustic and acid taste. The skin or paper is colored red-brown to dark-brown, the stain disappearing gradually. Iodine has neither an acid nor alkaline reaction, but slowly destroys all vegetable colors. It has the specific gravity 4.95, vaporizes slowly and without leaving any residue at ordinary temperatures, fuses near 115° C. (239° F.), congeals at 113.6° C. (236.5° F.), and boils above 175° C. (347° F.), according to Stas, when quite pure at 250° C. (482° F.); its vapor has the density 8.7, and a reddish or purple, or above the boiling-point a deep-blue, color. Iodine dissolves with a brown-yellow color in about 60 parts of glycerin, and in 7000 parts (Gay-Lussac) (65,000 parts, according to Dossios and Weith) of water, and forms with it gradually hydriodic acid, which dissolves more iodine; its solubility in water is also increased by tannin and by many salts, and particularly by iodides. It requires for solution about 11 parts of alcohol at 15° C. (59° F.), and dissolves freely in ether, both solutions having a brown color; it is easily soluble in chloroform, carbon disulphide, benzol, and other hydrocarbons with a purplish or violet color.

Iodine is readily recognized by the blue color which it imparts to starch-paste, by which test $\frac{1}{40000}$ part of free iodine is recognized. Water containing traces of free iodine will yield it to carbon bisulphide, etc., in which solution it is recognized by the purplish

color and by the blue color produced with starch-paste. Iodine in combination must previously be liberated by chlorine gas, avoiding an excess of the latter, or, if present as iodate, sulphurous acid or other deoxidizing agent will set it free.

Impurities and Adulterations.—At present iodine is usually met with in commerce in a very pure condition, containing but minute quantities of impurities. An excessive proportion of water is indicated by the iodine adhering to the bottle, and may be removed by placing it under a bell-glass over oil of vitriol at a low temperature; moist iodine yields with benzol or chloroform a turbid solution, from which the water gradually separates, the solution becoming clear. Cyanogen iodide and iodine chloride are rather freely soluble in water, and their solutions dissolve iodine with a brown color; they may be separated by heating the iodine in a suitable apparatus for about 15 minutes to 100° C. (212° F.) and cooling the vapors well; the former impurity will sublime as white or yellowish needles, the latter as hyacinthine-red prisms or red-brown oil; both have a pungent odor. For their detection the following processes are given: "If the iodine be removed from this dilute aqueous solution by agitation with disulphide of carbon, and after the separation of the latter some dilute solution of ferrous sulphate with a trace of ferric chloride be added, finally solution of soda, and the whole supersaturated with hydrochloric acid, no blue precipitate should make its appearance (absence of cyanide of iodine)."—*U. S.* Instead of removing the iodine by carbon disulphide, the solution is directed to be decolorized by sodium sulphite (or hyposulphite), and further treated with ferrous and ferric salt and soda, as stated.—*P. G.* The aqueous solution of iodine, on being decolorized with an excess of ammonia and completely precipitated with silver nitrate, should yield a filtrate which, on being supersaturated with nitric acid, should merely give a turbidity, but no precipitate (chlorine and bromine).—*P. G.* The following is the same test somewhat modified: If iodine be dissolved in sulphurous acid, the solution strongly supersaturated with ammonia, and completely precipitated by nitrate of silver, the filtrate, on being supersaturated with nitric acid, should not at once become more than faintly cloudy (absence of more than traces of chlorine or bromine). The amount of iodine is estimated in solution with potassium iodide and water by decolorizing with volumetric solution of hyposulphite, as follows:

0.633 Gm. iodine,	1 Gm. potassium iodide,	250 Ccm. water require	50 Ccm. vol. solution,	<i>U. S.</i>
0.2 " " 0.5 " "	" " " 50 " "	" " " 15.5-15.7 "	" "	<i>P. G.</i>
12.7 gr. " 15 gr. "	" " " 1 oz. "	" " " 1000 grain-measures,	<i>Br.</i>	

By this test absolutely pure iodine is required by the *U. S.* and *Br. P.*, while impurities not exceeding 1.5 per cent. are permitted by the *P. G.* Fixed impurities, such as graphite, charcoal, sawdust, metallic compounds, etc., are left behind on volatilizing a little iodine from a porcelain capsule.

Compounds.—Iodine combines in several proportions with oxygen, the most important compound being *iodic acid*; it unites with hydrogen to hydriodic acid, and combines with most of the other elements and with many organic compounds.

The iodides of metals are partly crystallizable, and are either white or not unfrequently of a bright color. With the exception of those of gold and allied metals, they are mostly not decomposed by heat, except in contact with air or with oxidizing agents. The alkali iodides are more volatile than the corresponding chlorides, and on being heated with calcium sulphate in the air evolve iodine, while alkali sulphate and calcium oxide remain behind. The iodides are decomposed by chlorine, bromine, nitric acid, and strong sulphuric acid, and on being heated with acid sulphates. Most of the iodides are soluble in water, and these solutions are precipitated dingy white by cuprous and cupric salts, the latter liberating a portion of the iodine; bright yellow by lead salts; brown by bismuth salts; green-yellow by mercurous salts; scarlet-red by mercuric salts; yellowish-white by silver salts; yellow or green with gold salts; black with palladium salts; and dark-brown by platinum salts, the solution acquiring at first a deep brown-purple color.

Pharmaceutical Uses.—**PHENOLUM IODATUM.** Iodized phenol, recommended by Dr. R. Battey (1876), is prepared by combining with a gentle heat 1 part of iodine with 2 parts of crystallized carbolic acid. It is solid in cool weather.

SYRUP OF IODOTANNIN. Debaucque observed that a solution of tannin will dissolve a considerable amount of iodine without reacting with starch. Demolon has suggested a syrup containing this compound, which is made by dissolving 3 Gm. of iodine and 18 Gm. of tannin in 300 Gm. of water, evaporating the solution until 60 Gm. are left, which are mixed with 960 Gm. of simple syrup.

Iodine is contained in the following officinal chemical compounds: *Amylum iodatum*,

Arsenici iodidum, *U. S.*; Cadmii iodidum, Ferri iodidum, *Br.*; Hydrargyri iodidum rubrum, Hydrarg. iodid. viride, *U. S., Br.*; Iodoformum, *U. S.*; Plumbi iodid., Sulphuris iodidum, *U. S., Br.*

The following pharmaceutical preparations likewise contain combined iodine: Linim. potass. iodidi cum sapone, *Br.*; Liquor arsen. et hydrarg. iodidi, *U. S.*; Pilulæ ferri iodidi, Syrup. ferri iodidi, *U. S., Br.*; Unguent. cadmii iodidi, Ferri iodidum saccharatum, *U. S.*; Ung. hydrarg. iodidi rubri, *Br.*; Ung. iodoformi, *U. S.*; Ung. plumbi iodidi, Ung. potass. iodidi, *U. S., Br.*; Ung. sulphur. iodidi, *Br.*

The following preparations contain free iodine; Linim. iodi, *Br.*; Liquor iodi comp.; Tinct. iodi, Ung. iodi, *U. S., Br.*; Vapor iodi, *Br.*

Medical Action.—*On Plants and Animals:* Iodine, being one of the most widely diffused of elementary bodies, may be presumed to be in harmony with life, and, in fact, it does promote the growth of vegetable organisms when its proportion is minute, but it hinders it and destroys their vitality when it is in excess. The proportion of it which may become hostile to animal life is exceedingly small, and it operates slowly and gradually by impairing nutrition, especially of glandular organs, while it occasions more or less irritation of the gastro-intestinal mucous membrane. The latter effect reaches ulceration when the dose is increased, and if a very large dose be given at once its effects are those of a corrosive poison.

On Man: Applied to the skin in ointment or in solution, iodine occasions a sense of warmth in the part, which, if the preparation be very strong, may amount to painful burning and cause redness and swelling of the surrounding integument. The tincture stains the skin a brownish-yellow; the color is more or less permanent, and may only disappear with exfoliation of the cuticle. It may be removed by solution of ammonia and by other articles mentioned below. It has generally been believed that iodine is absorbed by the skin, but carefully-conducted experiments appear to show that, at least in adults, when efficient means are taken to prevent the iodine vapors from reaching the mouth and nostrils, no trace of the substance can be found in the secretions. The rare cases of alleged poisoning by the application of iodine to the unbroken skin are contradicted by the experiments referred to. In children, however, the tincture of iodine applied to the unbroken scalp is said to have been absorbed, since its presence was detected in the urine, which, at the same time, became slightly albuminous.

The raw cutis, the mucous and the serous membranes, and the connective tissue give iodine ready access to the blood. It does not usually occasion severe inflammation when so applied, perhaps from the rapidity of its absorption. When the vapors of iodine are inhaled they irritate the mucous membranes and occasion headache, coryza, lachrymation, and cough. Their prolonged operation, as in certain manufactures, gives rise to dryness of the respiratory tract, dizziness, nervous disorder, etc. Absorbed iodine is readily detected, combined with sodium or potassium, in the blood, milk, tears, saliva, urine, serous effusions in closed cavities, etc. It is excreted chiefly by the kidneys as an alkaline iodide, even when it is taken into the stomach, and sometimes it occasions a temporary albuminuria. When given in full doses the tincture of iodine will sometimes occasion the coryza which is one of the usual effects of potassium iodide.

The direct effects of large doses of iodine (5–6 grains = $\text{Grm. } 0.30$), taken internally, are those of an irritant poison, such as heat and constriction of the throat, nausea, eructation, salivation, epigastric pain, vomiting, diarrhœa, and collapse. If reaction takes place the skin is apt to become intensely red. Notwithstanding the great severity of the symptoms, the death of a previously healthy person by the internal use of iodine is extremely rare—a circumstance due, doubtless, to its rapid absorption and elimination. On the other hand, medicinal doses have been known to occasion spasm of the larynx and severe gastric irritation, while very large doses have been taken at once, or excessive amounts in the course of a few weeks, without serious consequences. As an example of the former sort may be mentioned the case of a young man who swallowed a solution containing more than $2\frac{1}{2}$ drachms of iodine without experiencing any remarkable effects; and as an instance of the latter, the case of a woman who in the course of 80 days took 953 grains of iodine, in the form of tincture, without injury.

The chronic effects of iodine are manifested by all the organs. In the nasal passages, throat, and alimentary canal there are signs of irritation, with coryza, dryness, burning pain, dyspepsia, and diarrhœa: there is a tendency to loss of flesh and to wasting of certain glandular organs, especially the mammae and the testicles; the nervous system suffers from mental and sensory debility, impaired muscular power, and even general paralysis; the hair and the skin are apt to grow darker, and the latter is the seat of various

eruptions. Usually on ceasing the use of the medicine recovery from these effects gradually takes place. In medicinal doses iodine appears to promote nutrition and to stimulate glandular secretion. It is thought to excite the genital organs and increase the menstrual flow. Finally, it tends to prevent or to limit putrefaction, and thereby to correct the fœtor arising from this process.

Medical Uses.—In the following description of the internal uses of iodine its tinctures are intended unless it is otherwise stated. In *intermittent fever* iodine has been thought to display decidedly curative virtues both in the malarial regions of the tropics and in those of the temperate zones. The tincture was given in doses of from 5 to 15 minims (Gm. 0.30–1.00) three times a day, largely diluted. The compound tincture may be given in doses one-half larger. The reports published by Gibbons, Grinnell, Wadsworth, Atkinson, and Woods do not justify the favorable judgment entertained of iodine in this disease. The two last-named physicians, whose field of observation was Baltimore, concluded that in intermittent and remittent fevers iodine “is infinitely inferior to either cinchonidine or quinine” (*Amer. Jour. of Med. Sci.*, July, 1883, p. 77). *Typhoid fever* and other febrile affections have been treated by iodine, but without evident advantage. A physician has so far forgotten what is due to the authority of experience as to allege that “in simple, uncomplicated croupous *pneumonia*” half-drop doses of tincture of iodine given hourly “will arrest the further progress of the disease” (*London Med. Record*, May 15, 1881). *Mercurial salivation* may be diminished by its internal use. The iodide of potassium is less certain in its effects; if we might reason from its evident power of reviving mercury long quiescent in the system, its action should be mischievous when mercurial salivation already exists. *Constitutional syphilis* has sometimes been treated with iodine, but the potassic iodide has supplanted it in this respect. *Hypertrophy* of glandular organs is often reduced by iodine, especially of the mammae, testes, liver, and spleen, and of the thyroid gland in *goitre*. Indeed, it is probable that all cases of true goitre in persons under middle age are curable by iodine. For this purpose the compound solution should be administered in doses of from 5 to 10 drops (Gm. 0.30–0.60) three times a day. Its action upon the other organs mentioned, unless perhaps the mammae, is more equivocal. It has been used to reduce *polysarcia*. In all cases care should be taken to prevent the medicine from injuring the stomach by giving it largely diluted, while its internal is supplemented by its external use in proper cases. In *scrofula* iodine is most efficient in the glandular forms unconnected with a characteristic deposit; over the latter it has no direct influence. On the other hand, it is of great service in promoting the healing of scrofulous ulcers and curing caries of the same nature, especially in the chronic stages of that process. Anderson recommends iodide of starch (iodine gr. xxiv; starch ʒi), in doses of a heaped teaspoonful three times daily, as a remedy for *lupus erythematoses*, but not for *lupus vulgaris*. There is reason to believe that even *tubercles mesenterica*, or scrofula of the mesenteric glands, may sometimes be cured, and often palliated, by this medicine, especially if it is given, as in other scrofulous affections, with cod-liver oil. In some cases of *ascites* depending upon obstruction of the spleen, liver, or mesenteric glands iodine has proved curative, but in such cases the iodide of potassium is preferable. *Chronic articular rheumatism*, and that peculiar disease known as *nodosity of the joints*, have been treated with iodine internally, the former more successfully than the latter. *Excessive lactation* has been controlled by this agent in small and repeated doses, which are also sometimes successful in arresting the *vomiting* of pregnancy. The dose in the latter case should not exceed 2 or 3 drops (Gm. 0.10–0.15) of the tincture, and should be largely diluted. Gaunt (*Amer. Jour. of Med. Sci.*, Apr. 1883, p. 413) used this method in almost every other form of vomiting, whether arising from indigestion, phthisis, hysteria, intoxication, nephritis, or cholera infantum, etc., and with uniform success. Uterine disorders indicating impaired activity of function sometimes appear to be benefited by the use of iodine.

As a topical application it is used both for its counter-irritant and its constitutional effects. *Erysipelas*, when superficial, has often been arrested by the use of the tinctures of iodine, and, as far as any local treatment can go, they would seem preferable to solutions of nitrate of silver and other more or less caustic lotions. In *small-pox* it appears to retard the maturation of the vesicles, or even to prevent it altogether, and in addition to avert pitting. But its operation is not too confidently to be relied on. Lieutenant Payer states that a mixture of iodine and collodion proved most efficacious against *frost-bite* during the Arctic voyage of the Tegethoff in 1872. In *burns* and *scalds* its stimulant, substitutive, and protective operations are often useful, and the same may be said of certain cutaneous diseases, as *psoriasis*, *herpes*, *acne*, *favus*, and *lupus*. Its substi-

tutive action in the case of acne seems to be proven by the fact that when this eruption is caused by iodine the contents of the pustules have been found to give the iodic reaction with starch (*Bull. de thérap.*, xvii. 335). In favus and lupus a saturated solution of iodine in alcohol must be employed. The stimulant operation of iodine, as well as its deodorizing influence, is useful in *ozæna*; it is a valuable agent for inhalation in chronic affections of the air-passages, and especially in *laryngitis* and *bronchitis*, both in their original form and in that which accompanies *phthisis*. Like other local irritants, it may cure *aphonia* depending upon relaxation of the vocal cords or upon nervous debility. Iodine has been used topically in *diphtheria*, and probably with more advantage in this way than nitrate of silver. It is a most valuable topical agent in *leucorrhœa*, vaginal or uterine, and in chronic engorgements of the *uterus*. The same may be said of its utility in *gleet*, chronic *vesical catarrh*, and chronic *dysentery*. A gargle made with half an ounce of compound tincture of iodine in half a pint of water is efficient in mercurial *pygalism*, and a weak solution, as of 1 grain of iodine in an ounce of water, is one of the best means of retarding or curing *retraction of the gums*. A strong solution of iodine forms one of the best applications to chronic *ulcers of the tonsils, fauces, and uterus*, in *granular pharyngitis* and *conjunctivitis*, and in *blepharitis*.

In various chronic enlargements, especially of the superficial *glands*, iodine locally employed hastens the cure, and the same may be said of *mammary abscess* and of more chronic forms of inflammation, such as affect the *joints*. It sometimes promotes the removal of *pleural effusions*, and is adapted to relieve *muscular rheumatism* of the chest and *pleurodynia*, and probably to mitigate *chronic peritonitis*. Injected into the *tunica vaginalis testis*, the tincture of iodine, diluted with 2 parts of water, has long been used for the cure of *hydrocele*. In like manner, it has been employed to produce adhesion of the opposite sides of other serous cavities, such as *hernial sacs*, *synovial bursa*, and even *large joints*, as in the case of white swelling or *hyarthrosis*; *ascites* independent of organic mechanical causes has been cured in this manner, but, as such cases are extremely rare, the evidence in regard to the value of the operation is scanty. When paracentesis is practised in *chronic pleurisy* tincture of iodine is often injected, either to hasten the adhesion of the opposite pleural surfaces or to correct the fetor of the pleural secretion, or both at once. In recent cases the injection may consist of a watery solution of iodine in the proportion of from 2 to 5 grains in a pint (Gm. 0.10–0.30 in Gm. 500) of water; in more chronic ones a solution of 1 part of the compound tincture of iodine to 4 or 5 of water has sometimes been used. A similar method has been employed unsuccessfully in *hydrocephalus*. Numerous cases are recorded of the cure of *spina bifida* by means of iodic injections, and, among the more recent, those of McWhatt (*Edinb. Med. Jour.*, xxvi. 321), Gould and Clutton (*Trans. of Clinical Soc. of London*, xi. 75: xv. 191: xvi. 34), and Thiersch (*Boston Med. and Surg. Jour.*, May, 1881, p. 502). In England the following solution was employed: Iodine gr. x; iodide of potassium gr. xxx; glycerin ʒj. Of this about $\frac{1}{2}$ drachm was injected at each operation, and gentle but firm pressure by means of collodion and bandages constantly maintained. Injection of the tinctures of iodine has been extensively used in the case of *cysts* containing either serum, pus, blood, hydatids, or melicærous or atheromatous matter. In the case of *ovarian* serous cysts the operation has been remarkably successful when the tumor was unilocular. The puncture for evacuating the cyst and injecting the iodic liquid should be made above Poupart's ligament. *Fibrous tumors* of the uterus have been treated with iodine both topically and internally, and, although in some cases there has appeared to be an arrest or even a subsidence of the growth, the treatment cannot be depended upon to secure either. Indolent *abscesses* and *fistula* of all kinds are curable by injections of a solution of iodine, which appears to act by covering the diseased surface with a protecting film, by stimulating its curative processes, and by correcting the fetor of its secretions. In the first and last respects iodine is superior to nitrate of silver. The tincture of iodine has also been injected into *pulmonary cavities* by means of the needles usually attached to aspirators, and the result appears to be that the operation is less mischievous than might have been expected. Indeed, in some cases where a single superficial cavity existed the expectoration and general symptoms have for a time abated. In *malignant pustule* tincture of iodine has been administered internally, and also injected subcutaneously around the inflamed part, and apparently with excellent results (*Practitioner*, xxix. 290; *Archives générales*, Feb. 1882, p. 204). A case is reported in which severe inflammation produced by the fumes of *cashew-nut* (*Anacardium occidentale*) was treated without advantage with lotions of bicarbonate of sodium and of cold water, but at once subsided under the topical use of tincture of iodine. The application was very painful (*Am. Jour. Phar.*, June, 1881, p. 281). Iodine has been used in the

treatment of *poisoned wounds*, and is probably the most trustworthy application to wounds made by *venomous serpents*. Brainard formerly testified to the efficacy of iodine as a local antidote to the rattlesnake's venom, but Dr. S. W. Mitchell's experiments led him to an opposite conclusion. Dr. G. H. Carpenter of West Virginia published several cases in which the use of iodine locally and internally seemed to counteract the poison of the copperhead snake (*Med. News*, xlii. 441). One physician refers to twenty-five cases of bites by *rabid animals* in which the wounds were treated by a strong solution of iodine until active suppuration took place. In not one of these cases did rabies occur (Mussey). Although the evidence so far is entirely negative, there is much reason to believe that iodine must be superior to the other caustics used in such cases with the hope of preventing *hydrophobia*. *Iodide of starch* has been recommended by Bellini as an antidote to *poisons* generally. It is free from any disagreeable taste, and, not being an irritant, can be administered in large doses (*Boston Med. and Surg. Jour.*, Aug. 1879, p. 267). Diluted compound tincture of iodine is said to have been used successfully to dissolve a splinter of iron imbedded in the cornea (*Practitioner*, xxviii. 377).

The best antidote for a poisonous dose of an iodic preparation is starch or wheaten flour mixed with tepid water. White of egg and also milk are efficient. A solution of carbonate or bicarbonate of sodium may be given as a chemical antidote. Free vomiting should be encouraged as long as the liquid rejected tinges blue a solution of starch. Opium, counter-irritants, and repose of the stomach are indicated to allay gastric irritation.

Administration.—Its *dose* in various forms represents about $\frac{1}{4}$ grain of iodine (Gm. 0.016). It is seldom given, in substance, by the stomach. Its vapors are sometimes inhaled in laryngeal and pulmonary affections, and externally it is applied to the skin as iodized cotton or in bags or pads containing it in powder. To attenuate the local action of iodized cotton applied to the ear, vagina, etc. a wad of this material may be wrapped in simple cotton wadding and left *in situ*. These methods are more efficient than painting the part with solutions of iodine. The discoloration of the skin produced by it may be removed by ammonia, carbolic acid, soap liniment, or sulphite of sodium. For internal administration the simple or the compound tincture is to be preferred. As the simple tincture is precipitated by water, the compound tincture (*U. S. P.* 1870) is more suitable for this purpose. The remarkable solubility of iodine in oil of bitter almonds, and the permanency of the union, render the solution convenient for topical application and for addition to other preparations for internal administration, and especially to cod-liver oil. 20 grains (Gm. 1.30) of iodine will in the course of 2 months become perfectly dissolved in 60 grains (Gm. 4) of oil of bitter almonds. Of this solution about 15 grains (Gm. 1) may be added to cod-liver oil 1 pint (Gm. 500). A teaspoonful of this solution contains about $\frac{1}{32}$ gr. (Gm. 0.002) of iodine and $\frac{1}{10}$ gr. (Gm. 0.006) of oil of bitter almonds (Blackwell).

IPECACUANHA, *U. S.*, *Br.*—IPECACUANHA.

Radix ipecacuanhæ, P. G.—*Ipecac*, E.; *Ipécacuanha*, *Racine brésilienne*, Fr.; *Brechwurzel*, *Ruhrwurzel*, G.

The root of *Cephaelis Ipecacuanha*, A. Richard, C. emetica, Persoon, Callicocca *Ipecacuanha*, Brotero. Steph. and Church, *Med. Bot.*, plate 62; Woodville, *Med. Bot.*, t. 274; Bentley and Trimen, *Med. Plants*, 145.

Nat. Ord.—Rubiaceæ, Coffeæ.

Origin.—The drug first became known in Europe in 1672, and a few years after was successfully employed by Helvetius, a Dutch physician living in Paris, from whom (in 1688) Louis XIV. purchased the secret for 1000 louisdors and made it public. Two varieties of the plant are known—one with a woody and the other with an herbaceous stem—both being indigenous to the damp forests of Brazil, New Granada, and the north-eastern portion of Bolivia between about 8° and 22° S. lat. The plant has a spreading root, a stem 12 to 18 inches (30 to 45 Cm.) high, opposite, nearly entire, and somewhat hairy leaves, and small white flowers in a dense head, followed by a cluster of dark purplish-blue berry-like fruits, each containing two plano-convex hard nuts. The plant has been introduced into India, and is cultivated to some extent in Sikkim with but moderate success. In Brazil the roots are collected at all seasons, but principally from January to March; they are dug up by means of a stick and pulling the stems, fragments of the roots remaining, which again produce plants from adventitious buds. The roots are dried in the sun, and finally packed in bales. The importation into the United States has increased from 15,000 pounds in 1876 and 1877 to 39,000 pounds in 1881 and 1882.

Description.—The young, thin, and thread-like

FIG. 161.

Ipecacuanha.

roots are rejected; the older roots are in pieces of 2 to 6 inches (5–15 Cm.) in length and about $\frac{1}{8}$ inch (4 Mm.) thick; are mostly simple, bent, and contorted, and externally usually of a dull-gray color, but occasionally of a reddish or blackish tint. The root consists of a thin, toughish, white, and finely-porous ligneous cord, with no distinct medullary rays, and of a thick, brittle bark, which is finely wrinkled and closely annulated by projecting circles, the depressions between the rings being often fissured to the wood. The root breaks with a whitish granular and waxy fracture in the bark, which constitutes 75 to 80 per cent. of the weight and is easily separable from the wood. The bark consists, aside from the thin cork-layer,

FIG. 162.

Ipecacuanha-root, transverse section, magnified 65 diam.

altogether of parenchyma, without any radiating arrangement, the cells being filled with small starch-granules and becoming smaller near the wood; the latter has a radiating arrangement, and is composed of more or less elongated and fusiform, rather thick-walled, and pitted wood-cells, containing starch and having upon transverse section a nearly quadrangular shape. A variety imported from Carthagena is usually thicker, about $\frac{1}{4}$ inch (6 Mm.) in diameter, less conspicuously annulated, and with more distinct medullary rays. Small portions of the thin non-annulated stem are not unfrequently found attached to some of the commercial roots. The odor of ipecacuanha is slight, but heavy and nauseous, and the taste bitterish, somewhat acrid, and nauseating. The root yields a light brown-gray powder.

Constituents.—The common constituents of the root are starch, gum, pectin, sugar, a little fat, and a trace of volatile oil; the important principle is the alkaloid *emetia* or *emetine*, which is combined with *ipecacuanhic acid*. Emetine was discovered in 1817 by Pelletier and Magendie, and is obtained by evaporating the alcoholic tincture of the root to a syrupy consistence, adding potassa in excess and in a well-filled bottle to prevent access of air, and agitating with chloroform; the chloroformic solution is evaporated, the residue treated with a weak acid, filtered from the resinous matter, and precipitated by ammonia. Lefort takes advantage of the insolubility of the nitrate, which is thrown down from a strong solution of the extract by a concentrated solution of potassium nitrate; it is dissolved in alcohol, decomposed by milk of lime, the alkaloid taken up by ether, and purified as above. It is a grayish or whitish inodorous powder having a bitter taste and an alkaline reaction to test-paper. It is sparingly soluble in cold water, freely so in alcohol and chloroform, less soluble in ether, benzol, benzin, and fixed oils. Nitric acid or nitrates yield with it a slightly soluble brown salt; other dilute acids dissolve it readily, and yield mostly non-crystallizable salts, the solutions of which are precipitated by the general reagents for alkaloids and by potassium nitrate at 70° C. (158° F.). Emetine fuses like wax, and at a higher heat burns without leaving a residue. Its formula, according to Lefort and Würtz (1877), is $C_{25}H_{40}N_2O_3$, and from a concentrated alcoholic solution it may be obtained in groups of fine needles; the yield is little over 1 per cent. By titration with Mayer's solution Zenoffsky (1872) found 3.75 per cent. of emetine; much larger yields have occasionally been reported, but are probably over-estimated. Power (1877) observed that emetine is colored bright-yellow or orange by chlorinated lime; a little acetic acid favors the reaction, which is still observable when dissolved in 6000 parts of water.

Ipecacuanhic acid, $C_{14}H_{18}O_7$, was by former investigators supposed to be identical with gallic acid. Willigk separated it from the precipitate obtained in the decoction by lead acetate, by dissolving in acetic acid and precipitating with subacetate of lead. It is amorphous, brown, very bitter, hygroscopic, soluble in alcohol, little so in ether, colors ferric salts green, and is a glucoside. It appears to be related to caffeeo-tannic acid.

Podwyssotzki (1880) named the coloring principle of ipecacuanha *erythrocephalein*, because it acquires a deep purple-red color with alkalis. According to Reich, the bark contains about 30 per cent. and the wood over 7 per cent. of starch.

Tests.—Mix 10 grains of ipecac with 3 grains of lime and a few drops of water; dry in a water-bath, exhaust with 2 fluidrachms of chloroform containing a minute quantity of acetic acid, evaporate the chloroformic solution; add to the residue 2 drops of water, and add a saturated solution of potassium nitrate, which will give an amorphous precipitate to which Power's test may be applied; the wood treated in the same way gives no precipitate, but yields with tannin or potassio-mercuric iodide a slight turbidity (Flückiger). "Agitate the powdered root with 5 parts of warm water, filter after 1 hour, and add potassio-mercuric iodide, which should produce a copious white amorphous precipitate. If 0.2 Gm. of ipecac be agitated with 10 Gm. of hydrochloric acid, a portion of the filtrate should become blue on the addition of iodine-water, and another portion should become bright-red when a little chlorinated lime is sprinkled upon it."—*P. G.*

Adulterations.—Besides small portions of the stem, the commercial root is usually free from impurities, and the false ipecacuans described below are easily distinguished from the above. But powdered ipecacuanha is said to be sometimes adulterated with various farinaceous substances and with the powder of other roots, which may be detected by the microscope. Almond meal has also been mentioned; the large oblong cells of the scurfy testa and the hexagonal cells of the embryo which are free from starch, but contain oil-drops, readily characterize it under the microscope.

Pharmaceutical Uses.—EMETINUM COLORATUM, which is sometimes used, is made by exhausting ipecacuanha with alcohol, evaporating the tincture to a syrupy consistence, diluting with water, filtering, evaporating the filtrate to dryness, and powdering. The yield is about 3 per cent.

Off. Prep.—Extract. ipecacuanhæ fluid., *U. S.*; Pilula conii comp., Pilula ipecac. cum scilla, *Br.*; Pulvis ipec. et opii (ipecac. comp.), Trochisci ipecac., Troch. morphinæ et ipecac., *U. S.*, *Br.*; Vinum ipecac., *Br.* Syrup, compound tincture, and wine of ipecac, *U. S.*, are prepared from the fluid extract.

Allied Drugs.—Several emetic roots, known in South America as ipecacuanha or by the Brazilian designation *poaya*, have occasionally been sent to this country as substitutes: none, however, have any particular resemblance to the cephaëlis-root. The following, of which the plants yielding the first three belong to the natural order of Rubiaceæ, are the most important:

1. **STRIATED IPECACUANHA**, from *Psychotria* (Ronobea, *Richard*) emetica, *Mutis*, is $\frac{1}{2}$ to $\frac{3}{4}$ inch (6-8 Mm.) thick, blackish-gray, longitudinally striate; the bark has deep circular fissures at irregular distances; is thick, internally purplish-brown. The root is free from starch, contains much sugar, and has a sweet afterward bitter taste. The bark consists of parenchyma, which is not radiating, some of the cells containing acicular crystals; the wood resembles that of ipecacuanha, but the cells are larger and the cell-walls thinner. It is employed in New Granada and Peru.

FIG. 163.

Striated Ipecacuanha.

2. **SMALL STRIATED IPECACUANHA**, noticed by Planchon (1872), probably obtained from a species of *Richardsonia*, resembles the preceding, but is much smaller, and only $\frac{1}{2}$ to $\frac{1}{4}$ inch (2-4 Mm.) thick, gray-brown or blackish-brown, finely striate, has a thick bark, containing starch; a thin somewhat radiating bast-layer and a thick wood with thick-walled wood-fibres, large dotted ducts, and very fine medullary rays. Its taste is somewhat acrid, not sweet.

3. **UNDULATED OR FARINACEOUS IPECACUANHA**, from *Richardsonia scabra*, *Linné*, a native of Brazil, is, in the fresh state, white when dry, brownish externally, and white farinaceous internally; it is irregular undulate, fissured on alternate sides, and of a somewhat knotty appearance. The non-radiating bark-tissue consists of parenchyma containing starch; the wood is striate by medullary rays, and consists of thick-walled wood-fibres and large dotted ducts.

4. **WHITE LIGNEOUS IPECACUANHA**, from *Ionidium Ipecacuanha*, *Ventenat* (Nat. Ord. Violaceæ), indigenous to Brazil. The root is several inches long, about $\frac{1}{4}$ inch (6 Mm.) thick, several-headed, somewhat tortuous, not annulate, light-gray or yellowish, internally whitish, and with a yellowish, finely-porous wood, traversed by delicate medullary rays.

5. **BASTARD IPECACUANHA**, from *Asclepias currasavica*, *Linné* (Nat. Ord. Asclepiadaceæ), indigenous to the West Indies and South America. It has a very short root-stock, which is abruptly divided into numerous thin, pale yellowish-brown, and internally whitish rootlets. It is used in the West Indies like ipecacuanha.

FIG. 164.

Undulated Ipecacuanha.

6. INDIAN IPECACUANHA, from *Tylophora* (*Asclepias*, *Linne*) *asthmatica*, *Wight et Arnott* (Nat. Ord. *Asclepiadaceæ*). (Bentley and Trimen, *Med. Plants*, 177). The root-stock is short, knotty, about $\frac{1}{2}$ inch (3 Mm.) thick, emitting a considerable number of thin, wiry, brittle, and pale yellowish-brown rootlets. The outer portion of the bark contains large parenchyma-cells, filled with starch and with crystals of calcium oxalate. The drug has little odor; its taste is sweetish afterward acrid. It is free from tannin.

BATIATOR, a Senegambian root from an undetermined plant, is said to have properties similar to those of ipecac. It consists of a knotty and hairy root-stock with fascicles of thick rootlets, which are 10 or 12 inches (20-30 Cm.) long, somewhat flexuose, longitudinally wrinkled, more or less transversely fissured, yellowish- or grayish-brown, breaking with a smooth fracture, inodorous, slightly acrid, and nauseous.

GARDENIA CAMPANULATA, *Roxburgh* (*Rubiaceæ*). The shrub is indigenous to India. The roundish-ovate, slightly five-furrowed yellow berries are said to be cathartic and anthelmintic.

Physiological Action.—Pure emetine is a powerful local irritant, occasioning inflammation, and even ulceration, of the tissues to which it is applied. Powdered ipecacuanha produces similar but less profound lesions. Friction of the skin with an ointment containing either substance excites, sooner or later, a pustular eruption like that produced by tartar emetic. 2 grains of pure emetine suffice to kill a dog. In less toxic doses it occasions vomiting, great depression of muscular power and of temperature, and diminished frequency and tension of the pulse. After death the mucous membrane of the stomach and bowels is, according to some, injected, and according to others pale. These varying results appear to occur whether the poison be given by the stomach, rectum, or veins, or even hypodermically. Moreover, if long continued by either mode of administration it occasions ulcers of the stomach and small intestine, which are limited to the mucous glands of these organs, and hence are attributed to the elimination of the poison through those glands. The balance of opinion is in favor of the view that nausea and vomiting from ipecacuanha are due to its action upon the nervous centres, and not to its influence upon the gastric terminations of the pneumogastric nerve. Other experiments appear to support the belief that ipecacuanha excites the bronchial secretion, and in poisonous doses causes pulmonary congestion (*Podwyssotzki, Archiv f. exper. Path.*, etc., xi, 231). Rutherford and Vignal found that 60 grains of powdered ipecacuanha, mixed with a small quantity of bile and placed in the duodenum of a dog, "powerfully stimulated the liver;" but owing to the admixture of bile with the drug this experiment appears to us inconclusive. Pécholier in 1862 showed that in animals poisoned by emetine the lungs were pale and almost bloodless, and pointed out that this effect was not due to ipecacuanha merely as a cardiac sedative, for tartar emetic, which is also a cardiac sedative, does not induce pulmonary anæmia (*Bull. de therap.*, xvii, xlix).

The experiments of Dr. Foulkrod (*Inaugural Thesis*, Univ. of Penna., 1878) led him to conclude that emetine in contact with muscular fibres paralyzes them; that it reduces arterial pressure by debilitating the heart; that it produces sleep or coma by a direct action upon the brain; that it causes spinal convulsions; that it excites vomiting by a local action on the stomach; that it is eliminated unchanged by the kidneys, and also by the gastro-intestinal mucous membrane; that it occasions albuminuria; and that after poisoning by it glucose is found in the liver.

In man the effluvium or dust of ipecacuanha is apt to occasion coryza and congestion of the larynx and bronchia, causing dyspnœa, cough, and sometimes the rejection of fibrous sputa. Some persons have a special susceptibility to these effects. In exceptional cases the conjunctival inflammation reaches a high grade and is accompanied by neuralgia of the face and scalp. Internally and in small and repeated doses ipecacuanha occasions malaise, depression, yawning, salivation, eructation, and nausea, with retching or vomiting. Its emetic operation is not protracted and distressing like that of tartar emetic, but it tends to relax the bowels if they were previously in a normal state, and to augment the purgative action of cathartics.

Like many other medicines, ipecacuanha in repeated doses sooner or later brings about toleration, and produces very different effects from the primary emetic phenomena. But the dose of ipecacuanha is not, at any time, a sure criterion of the effects to be expected from it. Often, 4 or 5 grains of it will vomit as much as 12 grains. While $\frac{1}{16}$ grain of emetine given to an adult occasioned vomiting, in another case 12 grains were administered within 24 hours without exciting either vomiting or diarrhœa. Allowance must be made for the varying degrees of activity of the preparations employed, as well as for the state of the patients who received them.

Medical Uses.—Although the experimental investigations above referred to indicate very little action of ipecacuanha upon the lungs, it is in affections of these organs that

the medicine has been so generally employed that it has come to be classed among expectorants. The conditions to which it is appropriate are dryness of the respiratory mucous membrane on the one hand, and excessive secretion and obstruction upon the other. Its mode of action in the two cases is different: in the former, given in small doses and in the first stage of ordinary *bronchitis*, it promotes the bronchial and laryngeal secretions, and thereby renders the cough less painful and frequent and more productive; in the latter, administered in large doses, it acts as an emetic, producing an expulsion of the contents of the air-tubes, while it renders their secretions less tenacious. It is in the former of these ways that it is so efficient in the commencement of the attacks referred to, and in the latter when the bronchia become filled with mucus, serum, or fibrin, as in *whooping cough*, *suffocative catarrh*, *capillary* and *chronic bronchitis*, *bronchorrhœa*, etc. In addition, perhaps, to these two modes of action a third or anti-spasmodic action may be recognized in its cure of *spasmodic croup* (spasmodic laryngitis), but quite as probably the relaxation of spasm it occasions is secondary to its sedative and, therefore, so far as the local disorder is concerned, depletory action. Like other nauseants, it has been found efficient in expediting labor by relieving *rigidity of the os uteri*. A similar operation, no doubt, explains the reputation of the medicine in *spasmodic asthma*. In *membranous croup* it is not without utility in virtue of the same influences, which, however, are inadequate to the occasion. It is far more efficient in the several diseases mentioned when they occur in children than in adults. The utility of ipecacuanha in *pneumonia*, which has been affirmed, is probably limited to two occasions—the forming or congestive stage of the disease, before solidification has taken place, and the declining stage, when the bronchia are apt to become obstructed with softened exudation-matter and mucus. In both conditions the emetic action of the drug is appropriate—in the former by diminishing the quantity of blood in the lung and the force of its propulsion by the heart, and in the latter by a mechanically evacuant operation upon the obstructed bronchia. It is probable that the utility of ipecacuanha in *hæmoptysis*, which formerly was admitted by Stoll, Trousseau, and others, depends upon this mode of action. It is true that some reporters have not found it useful in this hæmorrhage (Verardini, *Philæ. Med. Times*, xi. 430), but their results are contradicted by theory as well as experience—by theory based on experiment as above described, and by the clinical results of using large doses so as to induce speedy toleration; *e. g.* 90 grains infused in 4 fluidounces of boiling water and sweetened. A tablespoonful of this preparation may be given every hour or two (Péchohier).

The utility of ipecacuanha emetics in *hæmorrhage* from the stomach, uterus, etc. has long been known, but recently the use of repeated small doses of the medicine, without causing vomiting, has been very successful in such cases. Probably in hæmatemesis a full emetic dose should be first prescribed, after which smaller and only nauseating doses may be substituted. According to the modern views of the action of the medicine, it may be supposed to control hæmorrhage by contracting the capillaries, but the earlier explanation, that the heart was depressed and the blood no longer circulated so vigorously, should not be lost sight of.

Whether by direct stimulation or by indirectly promoting secretion, there is no doubt that this medicine has proved advantageous in *atonic dyspepsia*; that is to say, when digestion is laborious, painful, attended with flatulence, depression of spirits, cold extremities, etc. The dose should not exceed 1 grain, in pilular form, and may be taken in the morning fasting or else immediately after meals. The *vomiting of pregnancy* has sometimes been arrested by hourly doses of a single drop of wine of ipecacuanha. We have known it to arrest this symptom in a single day after it had continued for several weeks. There is some reason to believe, apart from the experiments above described, that ipecacuanha increases the secretion of bile, for large doses of it (20 grains), repeated daily, have relieved cases of catarrhal *jaundice* that had resisted other remedies (Cook, *Practitioner*, xxv. 104).

The title, *Radix antidysenterica*, originally applied to ipecacuanha, denotes the estimate then held of its dominant virtue. In Brazil it was the specific for dysentery, and its mode of administration was such as to produce vomiting first, and afterward tolerance of the medicine. The efficiency of such a method is intelligible in a country where dysentery is apt to assume a bilious type, and an analogy with it is found in a like treatment of the acute febrile diseases of hot climates which is everywhere adopted. In the present instance anti-bilious and anti-pyretic virtues are united in the same remedy. Other forms of acute dysentery than the bilious are not always as advantageously treated by ipecacuanha, and where in such forms the medicine has appeared to be most useful it has usually been combined with opium, whose share in the cure should not be overlooked.

Of whatever type the dysentery may be, the remedy is most efficient the nearer to the commencement of the attack it is administered. It ought to be given on an empty stomach, and no liquid should be taken for an hour or two after it is swallowed, the patient meanwhile keeping as still as possible. The original Brazilian method of administration was as follows: An infusion was made with 120 grains of the bruised root in 6 ounces of boiling water, and allowed to stand for 12 hours before the decanted liquid was used. A similar quantity of fresh water was then added to the dregs for the second day, and the same process was repeated on the third day. Each infusion was divided into two or more portions, one of which was given at intervals of two or three hours if the attack was mild, but the whole at one dose if the attack was severe. If vomiting occurred, the medicine was, after an interval, repeated. There can be no doubt that when it operates favorably the stools soon lose their dysenteric character and are voided without pain. In Peru it has been the custom to administer the powdered root mixed with a little syrup, and at the same time enemas made with an infusion of the root with the addition of laudanum. The enema has been found by many practitioners in Europe and elsewhere to be sufficient by itself when prepared in the following manner: "Take of bruised ipecacuanha 150 grains, and boil it in 5 fluidounces of water for 10 minutes; strain off the liquid, and repeat the operation with a fresh portion of water a second and a third time; mix the three portions of liquid and evaporate them in a sand-bath to 4 ounces; divide this product into two equal parts, and administer one night and morning by enema, directing them to be retained as long as possible" (*Polichronic*). A simpler and, apparently, as efficient a formula is to boil 60 grains of bruised ipecacuanha for 10 minutes in 5 ounces of water; let it infuse for 1 or 2 hours, and strain off the decoction. It is only in chronic cases with decided ulceration that any nausea is excited by these enemas. In so important a matter it is desirable to know something of the treatment of dysentery by ipecacuanha in India, where the disease is endemic and often very fatal. No higher authority on the subject could be cited than Surgeon-General Fayrer. His directions, somewhat condensed, are these: "The treatment of an attack of ordinary acute dysentery is to be conducted on the following plan: The patient should remain in a recumbent posture. A dose of 20 or 30 grains of ipecacuanha powder should be given to an adult at once in water, and the patient should resist vomiting as long as possible. It is recommended by some to give a dose of 15 or 20 drops of laudanum before the ipecacuanha, and apply a sinapism to the epigastrium. He must abstain from all fluids except occasional mouthfuls of iced water or bits of ice. My own plan has generally been to repeat the dose of ipecacuanha in 4 or 6 hours a second or third time, according to the effects, and especially if the first dose has been rejected, as it often is. I have generally found that if this treatment be resorted to early in acute dysentery it is most effective, and nothing else is needed. The pain diminishes, the tormina and tenesmus are alleviated, the restlessness is abated, the sense of fulness and desire to go to stool passes away, the skin becomes moist and the motions feculent and assume a peculiar yellow appearance." "When the disease has advanced to ulceration, and when the chronic stage has been fully established, the ipecacuanha is no longer useful" (*Med. Times and Gaz.*, Feb. 1881, p. 143). The advantages claimed for the treatment of acute dysentery by ipecacuanha are—the simplicity, safety, and promptness of its operation, its efficiency in curing, and the rapidity of the cure. Even in *chronic dysentery* the same method of employing it has been very successful, although it is not recommended by Fayrer.

This medicine has long been used in the treatment of *chronic diarrhœa*, either alone or associated with calomel and opium. Of late it has been administered alone, or guarded with opium to prevent its rejection, in *infantile diarrhœa*, in *tuberculous diarrhœa*, and in *chronic dyspeptic diarrhœa*. Of these forms, the one most beneficially influenced by the medicine is the infantile. If the patient is not much exhausted the medicine may be given at first by the mouth, otherwise by enema and in the form of infusion. The diarrhœa of consumption, being due sometimes to intestinal ulcers and sometimes to debility, as well as in both cases to the swallowing of sputa, the results of any treatment must vary with the cause of the symptom. In this case the utility of the medicine is least when the cause is most permanent. If it is too long employed it may create an irritation as great as that which it is intended to relieve. Whether it acts by substitution or astringency, or as a stimulant of the vaso-motor nerves, it very certainly diminishes the secretions of the affected part, and apparently does so during its elimination after absorption. The same mode of operation is probable in the case of *hectic sweats*, which are sometimes completely suspended by enemas of ipecacuanha infusion when other remedies have proved ineffectual. The treatment of *cholera morbus* and of *epidemic cholera* by this

medicine has been advocated by numerous physicians, who presented ingenious reasons for its use, but neither their opinion nor their practice has prevailed.

In bilious *remittent* and *intermittent* fevers, when gastro-hepatic congestion is indicated by the muddy eye and skin, and foul tongue, nausea, bitter taste, distended epigastrium and hypochondria, and perhaps bilious vomiting and diarrhoea, an emetic dose of ipecacuanha promptly palliates these symptoms and renders the action of quinine more immediate and certain. Ordinary *intermittent fever* is alleged to have been cured by doses of 1 or 2 grains every three or four hours. In all cases of *indigestion* due to the presence of food in the stomach, of *urticaria* produced by the same cause, and of *poisoning* where it is desired to expel the offending substance, ipecacuanha emetics may be advantageously employed.

As a local application to the eye in purulent *ophthalmia* when the active inflammatory symptoms have subsided, but chemosis remains, with a red and flabby state of the conjunctiva and cloudiness of the cornea, a decoction of ipecacuanha has been found efficient. It may be made by boiling 30 grains of bruised ipecacuanha for 10 minutes in 5 ounces (Gm. 2 in Gm. 160) of water. When cool the liquid should be strained off and instilled into the eye.

Administration.—As an emetic the *dose* of powdered ipecacuanha is 20 grains (Gm. 1.30), or 5 or 10 grains (Gm. 0.30–0.60) may be repeated every 10 minutes, the patient drinking freely of warm chamomile tea, or simply of warm water, as soon as the first signs of nausea appear. Or an *infusion*, prepared with 120 grains (Gm. 8) of the bruised root in 6 fluidounces (Gm. 190) of boiling water, may be given in doses of a fluidounce (Gm. 32) at intervals of 4 or 5 minutes. A *decoction* and its uses have been already described. As a *nauseant*, 1 or 2 grains (Gm. 0.06–0.12) of the powder may be repeated at short intervals; the same dose, at longer intervals, may be used as a diaphoretic and expectorant. For infants the syrup is preferable.

BATIATOR is used in its native country for the same purposes as ipecacuanha, as an emetic, and in the treatment of *dysentery*, in the same manner that ipecacuanha is employed in Brazil. The negroes are said to regard it as a sovereign remedy for *hemorrhoids*.

IXORA (*I. bandhuca* and *I. coccinea*), an East Indian plant, is said to be very efficacious in *dysentery*, and has been compared with ipecacuanha, although it has no nauseating effect. The whole of the fresh root is used to prepare a tincture which has an agreeable aromatic taste and is given in doses of 10 drops (Gm. 0.75) three or four times a day (*Bull. de thérap.*, xvii. 47).

IRIS, U. S.—IRIS.

Blue flag, Water flag, E.; Rhizome d'iris varié, Flambe variée, Glaïeul bleu, Fr.; Verschiedenfarbige Schwertlilie, Amerikanischer Schwertel, G.

The rhizome of *Iris versicolor*, Linné. Meehan, *Native Flowers*, i. 141.

Nat. Ord.—Iridacæe.

Origin.—The blue flag is common in wet and swampy meadows from Canada southward to Florida and westward to Minnesota and Arkansas, and flowers in the latter part of spring. The sword-shaped leaves are about as long as the stout stem, which bears a few showy blue flowers, having the three outer lobes of the corolla with a yellow blue-veined base, and the inner lobes paler.

Description.—The rhizome is horizontal, and grows in annual shoots or joints, bearing a flowering stem at their end and producing two, or often four, lateral branches.

The joints are 2 to 4 inches (5–10 Cm.) long, cylindrical at the base, the upper portion vertically flattened and $\frac{3}{4}$ to 1 inch (18–25 Mm.) broad; they have an annulated appearance from the projecting leaf-scars, and at the lower side are beset with simple rootlets, 4 to 6 inches (10–15 Cm.) long, and crowded near the broader end of the joint. The color of the fresh rhizome is yellowish-brown, when dry gray-brown, and internally gray or brownish. A distinct nucleus-sheath separates the cortical

Iris versicolor, Linné: joint of rhizome and section of branches.

A distinct nucleus-sheath separates the cortical

layer from the central portion, in which nearly all the scattered wood-bundles are contained; the parenchyma contains mainly starch and some crystals. The dry rhizome has no marked odor; its taste is acrid and nauseous.

Constituents.—The rhizome contains starch, gum, tannin, fat, and acrid resinous matter; the latter may probably represent its medicinal virtues. D. W. Cressler's experiments (1881) render it probable that blue flag contains a brownish viscid alkaloid which is soluble in amyl alcohol and in dilute acetic acid, and may be obtained from the alcoholic extract by treatment with acetic acid. The resin, amounting to about 25 per cent., is soluble in ether, chloroform, and hot alkalies, and from the latter solution reprecipitated by acids.

Off. Prep.—Extract iridis, Extract iridis fluid., U. S.

Allied Plants.—*IRIS VIRGINICA*, *Linné* (Meehan, *Native Flowers*, i. 189), the slender blue flag or *Boston iris*, and *IRIS VERNA*, *Linné*, the *dwarf iris*, have much smaller rhizomes than the pharmacopœial species, but they are otherwise of the same appearance and possess similar properties. The Boston iris grows near the coast southward to South Carolina; the dwarf iris is found on hillsides from Virginia and Kentucky southward.

Medical Action and Uses.—The fresh root has an acrid taste, and its expressed juice is emetic and cathartic, producing great prostration. Diuretic and cholagogue virtues are also ascribed to it. It was a medicine highly esteemed by the aborigines of this country. Its activity appears to depend upon its oleoresin ("iridin"), which may be used as a purgative in the dose of 1 or 2 grains (Gm. 0.05–0.10.) According to the experiments of Rutherford and Vignal, 5 grains of iridin, when mixed with a little bile and water and placed in the duodenum of a dog, very powerfully stimulated the liver. It is also a decided stimulant of the intestinal glands. It appears to be less irritant than podophyllin and a less active cholagogue, but its purgative effects are greater than those of euonymin. It may be used as a cathartic in constipation associated with evidences of imperfect hepatic action. The *dose* of the dried root is stated to be from 10 to 20 grains (Gm. 0.60–1.30).

IRIS FLORENTINA.—FLORENTINE ORRIS.

Rhizoma iridis, P. G.; *Radix iridis Florentinæ*, *Radix ireos*.—*Orris-root*, E.; *Iris de Florence*, Fr.; *Veilchenwurz*, G.

The rhizome of *Iris germanica*, *Linné*, *I. pallida*, *Lamarek*, and *I. florentina*, *Linné*. Stephenson and Church, *Med. Bot.*, i. t. 27; Bentley and Trimen, *Med. Plants*, 273.

Nat. Ord.—Iridaceæ.

Origin.—Florentine orris, or *white flag*, is found in dry localities from the southern shores of the Black Sea westward along the north shore of the Mediterranean; though wild near Florence and Luca, Hanbury does not regard it as indigenous to those places. It has large sweet-scented white flowers, the sepals with a yellow beard and brownish veins. It is cultivated together with *Iris pallida*, which is likewise indigenous to Southern and South-eastern Europe, has a rather tall stem, and pale-blue or purplish flowers, and with *Iris germanica*, which is indigenous to Southern Europe, and is met with in Northern Africa and Northern India; this has a lower stem, bears deep-blue or purplish-blue flowers, and is known in England as *blue flag*, in France as *flambe*, and in Germany as *Blauer Schwertel* or *Schwertlilie*. The rhizomes of the three species are collected, and, as it appears, those of the last two much more frequently than of the first. They resemble each other very closely, and, though the branches of the second species are usually broad and stout, there are no permanent characters by which they may be distinguished. The rhizomes are collected in the latter part of summer, peeled, and dried in the sun. 28,000 pounds of orris-root reached the United States in 1877, and 223,870 pounds in 1882.

Description.—The horizontal rhizome is composed of joints, which are 2 to 4 or 6 inches (5 to 10 or 15 Cm.) long, the broadest part near the apex, about 1 to 1½ inches (25–40 Mm.) wide, tapering below, and abruptly narrowed above to the circular stem-scar, from two sides of which similar joints are produced. The rhizome is vertically compressed, and when peeled of a white or whitish color externally and internally. The leaf-scars on the upper side are indicated by transverse lines of fibro-vascular bundles, and the rootlets on the lower surface by circular brownish scars, which are more crowded near the upper end. The texture is firm, the rhizome breaks irregularly, and shows upon the transverse fracture, near the surface and parallel with it, a distinct nucleus-sheath enclosing a number of scattered wood-bundles. The parenchyma-cells enclose mainly

small oblong or elliptic starch-granules and few crystals. Orris-root has an agreeable violet-like odor, which is slowly developed on drying, and a mealy afterward bitterish and somewhat acrid taste. The powder has a whitish color.

Constituents.—Orris-root contains a minute quantity of volatile oil, which is solid, crystalline, and of a pearly lustre, as described by Dumas (1835). By distillation with steam about .8 per cent. of a solid crystallizable substance is obtained, which Flückiger found to consist mainly of *myristic acid* impregnated with a little volatile oil; this acid, however, does not pre-exist in the rhizome. This constitutes the commercial *oil of orris-root*, but a *liquid oil of orris* has appeared in the market, which is said to be made by adding oil of cedar-wood to the crushed rhizome and distilling the mixture with water. Orris-root contains also a large quantity of starch, some soft brownish resin of an acrid taste, and a little tannin which colors ferric salts green.

Adulterations.—The rhizomes of other species of *Iris* in most cases resemble the officinal one in shape, but are destitute of its agreeable odor; those of *Iris pseudacorus*, *Linne*, and *I. foetidissima*, *Linne*, which are indigenous to Europe, have a dark color and a more astringent and acrid taste, and cannot be mistaken for Florentine orris. The adulteration of powdered orris is best detected by the microscope from the different shape of the starch-granules contained in the material employed for the purpose.

Medical Action and Uses.—The fresh root is said to possess irritant properties, and, taken internally, to cause colic, vomiting, and purging, while the dry root acts as a moderate digestive stimulant. When powdered and applied to the nostrils it excites sneezing and increased secretion, and in the mouth a flow of saliva. It is asserted that when freely sprinkled in the hair it has caused alarming nervous symptoms. It was formerly used along with more active medicines in the treatment of *chronic diarrhœa* and *bronchitis*, and also as a diuretic and sternutatory. A piece of the root was, and occasionally is still, employed for children to bite upon while teething; it probably excites salivation and mitigates the pain of the process. *Iris* is also used to make issue "peas," is often added to dentifrices on account of its aromatic flavor and its favorable action on the gums, and is an ingredient in *pastilles* used for the same purpose or to conceal fetor of the breath. Its liability to be attacked by insects renders care in its use as an issue "pea" desirable. The dose of the powdered rhizome may be stated at from 5 to 15 grains (Gm. 0.30–1).

JALAPA, U. S., Br.—JALAP.

Tubera jalapæ, P. G.; *Radix jalapæ*.—*Jalap*, Fr.; *Jalape*, *Jalapenknollen*, G.

The tuberous root (tubercles) of *Exogonium Purga*, *Bentham* (*Bot. Mag.*, vol. lxxiii. plate 4280; *Bentley and Trimen, Med. Plants*, 186), *Ipomœa Purga*, *Hayne*, *Convolvulus Purga*, *Wenderoth*, C. Jalapa, *Schiede*, *Ipomœa Schiedeana*, *Zuccarini*, *Ipom. Jalapa*, *Nuttall*.

Nat. Ord.—*Convolvulaceæ*.

Origin and Collection.—This twining herbaceous perennial is indigenous to the damp and shady woods on the eastern slope of the Mexican Andes, at an altitude of from 5000 to 8000 feet (1520–2440 M.) It has been introduced into India, and flourishes well in the Nilgherry Mountains. Its cultivation has also been carried on to some extent in Jamaica. The plant has alternate cordate leaves, acute at the apex and the basal lobes, and axillary cymes of three to five dark pink-colored flowers, with a long tube, spreading border, and protruding stamens. The tubers (hypertrophied roots, *Bentley*) are collected during the whole year, but principally in the spring. Owing to the wet climate, the drying cannot be effected by exposure to the sun, but is accomplished by suspending the tubers in a net over a wood-fire; the smaller pieces are dried entire, the larger ones are incised to facilitate the drying. The supply of jalap is very variable; in 1876 there were 4595 pounds of it imported into the United States, while in 1882 the importation reached 93,628 pounds.

Description.—*Jalap*, when fully developed, is napiform or depressed globose in shape, above marked by the scar of the overground stem, below suddenly contracted into a thin root. The tubers are often pyriform, ovate, oblong, or nearly cylindrical in shape, and vary in size from that of a walnut to 3 or 4 inches (37–50 Mm.) in diameter. They are externally of a dark-brown color, and usually of a smoky appearance, more or less longitudinally wrinkled, and beset with brown, broad, corky warts, becoming transversely confluent. *Jalap* is hard and compact, and breaks irregularly; the transverse fracture is not fibrous, and shows a distinct concentric arrangement. The bark is quite thin, gray-

brown, with a large number of resin-cells forming a dense zone near the cambium-line. The central portion of jalap has the resin-cells arranged in concentric circles, which vary in width, a zone of two or four rows of resin-cells usually alternating with one of a single row. The parenchyma consists of smaller cells containing sub-

FIG. 166.

Transverse section of Jalap.

globular starch-granules, which, particularly in the outer layers, are more or less transformed into a pasty mass; crystals of calcium oxalate are sparingly met with. The vascular tissue exists in small circularly-arranged groups of spiral vessels. Jalap has a very faint radiate appearance, the fibro-vascular bundles being small and not very numerous. It has a slight smoky and sweetish odor and a sweet-

FIG. 167.

Jalap: transverse section, nat. size.

ish afterward acrid taste. Good jalap should not be deeply wrinkled or sticky internally, but should be plump, heavy, and hard, and when fractured should present a resinous appearance.

Impurities and Substitutions.—Jalap appears to be sometimes collected in an immature state or at an improper season; at least many of the tubers frequently contain little resin, but otherwise present all the characteristics of genuine jalap. Occasionally jalap has been met with which has been previously deprived of the resin, and is then sticky upon the surface and of a dark color internally. Hager (1882) states that good jalap will sink in a solution of sodium chloride of spec. grav. 1.140, while if exhausted by alcohol it will float in this liquid. A *mealy jalap* has been observed which resembles true jalap externally, but has few scattered resin-cells and a mealy fracture. The so-called *jalap-stalks*, *male*, *fusi*form, or *woody jalap*, consist of the tuberous root of *Ipomoea orizabensis*, *Ledanois* (*Convolvulus*, *Pelletan*), often cut into transverse slices 2 to 3 inches (50–75 Mm.) broad, light-brown, compact, often horny, distinctly radiate and more fibrous in texture; it is spindle-shaped, 2 feet (60 Cm.) long, and contains resin which is entirely soluble in ether. *Tampico jalap*, from *Ipomoea simulans*, *Hambury*, forms globular or elongated tuberous pieces which are often smaller, but occasionally larger, than true jalap, deeply wrinkled, destitute of transverse scars, and of a more woody fracture; the resin contained in it is completely soluble in ether.

The tuberous root of *Mirabilis Jalapa*, *Linné*, or *Four-o'clock*, resembles jalap somewhat in shape, but is darker externally and contains a large number of acicular crystals.

Radix mechoacanæ, probably obtained from a *Convolvulacea*, is found always in sections, of whitish or gray color, destitute of resinous circles; it cannot be mistaken for jalap.

Valuation.—"On exhausting 100 parts of jalap by alcohol, concentrating the tincture, and pouring it into water, a precipitate of resin should be obtained which, after washing with water and drying, should weigh not less than 12 parts (10 p. Br. P. G.), and of which not over 10 per cent. should be soluble in ether."—*U. S.*

Constituents.—Jalap contains starch, gum, uncrystallizable sugar, and extractive matter; its medicinally important constituent, however, is *resin*, of which selected pieces may contain 22 per cent., but which varies in good commercial jalap between 12 and 18 per cent. Jalap grown in Jamaica yielded to Thos. Greenish (1881) only 8.27 to 8.68 per cent. of resin. About one-twelfth or one-tenth (occasionally one-eighth) of the resin is soluble in ether, of a brown color, acid reaction, and acrid taste; it is soluble in alkalis, and reprecipitated from these by acids. It is contained in the pharmacopœial resin of jalap, the main constituent of which is the resin insoluble in ether; this, investigated by Kayser (1844), was named *rhodocortin*, and by W. Mayer (1852) *convolvulin*. Pure convolvulin is colorless, transparent in thin layers, inodorous, and tasteless, but in alcoholic solution it has an acrid taste. It is insoluble, or nearly so, in carbon disulphide, chloroform, petroleum, benzin, and volatile oils, but dissolves in acetic and cold nitric acid; when dry it melts at 150° C. (302° F.), but at a much lower temperature if mixed with water. It consists of $C_{62}H_{106}O_{32}$, dissolves readily in caustic alkalis, and is not reprecipitated by acids, but converted into *convolvulinic acid*, $C_{62}H_{106}O_{35}$, of which convolvulin is the anhydride. Both are glucosides, and when boiled with dilute acids yield sugar and *convolvulinol*, $C_{36}H_{50}O_7$, which crystallizes in needles, is bitter and acrid, and when treated with alkalis loses water and is converted into *convolvulinic acid*, $C_{26}H_{48}O_6$. Convolvulin and its derivatives,

on being oxidized with nitric acid, are finally converted into oxalic and *ipomic acids*, the latter being $C_{10}H_{18}O_4$, and, according to Neison and Bayne (1874), identical with *sebacic acid*, one of the products of the destructive distillation of olein.

W. Mayer (1855) has very improperly given the name of *jalapin* to the resin obtained from orizaba-root, which, with all its derivatives, is homologous to the preceding. *Jalapin*, $C_{65}H_{112}O_{32}$, closely resembles convolvulin, but is soluble in ether and chloroform, also in acetone, benzol, and phenol. Dissolved in alkalies, it is converted into *jalapic acid*, $C_{68}H_{118}O_{35}$, which is soluble in water; when treated with dilute acids, into sugar and *jalapinol*, $C_{32}H_{62}O_7$, which is acrid; and with alkalies yields *jalapinolic acid*, $C_{32}H_{60}O_6$. Nitric acid oxidizes these compounds to oxalic and sebacic acids. Spirgatis (1860) considers jalapin chemically identical with *scammonin*.

The resin of tampico-root is likewise homologous. Spirgatis (1870) calls it *tampicin*, $C_{65}H_{108}O_{28}$, which yields with alkalies *tampicic acid*, $C_{68}H_{120}O_{31}$, and with diluted acids sugar and *tampicollic acid*, $C_{32}H_{64}O_6$.

Off. Prep.—Abstract jalapæ, *U. S.*; Pulv. jalapæ comp., *U. S., Br.*; Pulv. scammonii comp., *Br.*; Resina jalapæ, *U. S., Br.*; Tinctura jalapæ, *Br.*

Allied Plants.—Of the numerous species of *Ipomœa* which have been used like jalap, we mention the following in addition to those named above:

IPOMœA PANDURATA, Meyer, s. *Convolvulus panduratus*, Linné, grows on sandy banks in the United States, and is known by its pointed, heart-shaped leaves, which are sometimes contracted near the middle and fiddle-shaped. The root is elongated, cylindrical, 2 or 3 feet (60–90 Cm.) long, 1 to several inches (25 Mm. and more) thick, abruptly contracted above to the thickness of a finger. It is pale-brownish externally, grayish-white internally, and emits when wounded a resinous milk-juice. The resin-cells form a dense zone in the inner portion of the thin bark, and are irregularly scattered in the medullary rays. It is known as *man-root*, *man of the earth*, *wild jalap*, and *wild potato*, and is feebly cathartic. Analyzed by C. Manz (1881), sugar, gum, starch, a tannin-like body, and 1.5 per cent. of resin were obtained. The latter is purgative, completely soluble in alcohol, ether, chloroform, and potassa, and from the latter solution again precipitated by acids; it consists of an acid resin soluble in methyl alcohol and precipitated by lead salt, and of a non-acid resin, which, like the former, is a glucoside.

Five or six Brazilian Convolvulaceæ have tuberous roots containing purgative resins: though employed in their native country like jalap, they are not articles of general commerce. They are popularly known as *purga*, *batata purgante*, *jalapinha*, *jeticucá*, and *emburerebo*, and are obtained from plants of the genera *Convolvulus*, *Ipomœa*, and *Piptostegia*.

IPOMœA TURPETHUM, R. Brown, *turpeth-root*, is indigenous to India and the East Indian Islands. The root is met with in commerce in pieces of various length, $\frac{1}{2}$ to 1 inch (12–25 Mm.) thick, frequently with pieces of the woody stem attached, reddish-brown externally, internally grayish or brownish. The bark is thick, mealy, and contains numerous small brown resin-cells in concentric rows, and several, or in older roots numerous, woody groups. The central wood is pale-brown, porous, and divided by narrow medullary rays into four or six parts. The resin amounts to about 4 per cent., a portion of which is soluble in ether; the insoluble portion, *turpethin*, $C_{34}H_{56}O_{16}$, resembles jalap resin in its behavior to alkalies and dilute acids.

IPOMœA NIL, Roth, s. *Convolvulus* (Pharbitis, Choisy) Nil, Linné (Bentley and Trimen, *Med. Plants*, 185), is indigenous to the tropics, and grows spontaneously in the Southern United States. The seeds are about $\frac{1}{4}$ inch (6 Mm.) long, black, somewhat triangular, rounded on the back, of a rather heavy odor while fresh, and of a sweetish afterward acid taste. The seeds are known in India as *kaludana*, and roasted or in powder are used as a purgative, like, but somewhat weaker than, jalap; they contain a fixed oil and 8 per cent. of *pharbitisin*, which appears to be identical with convolvulin (*Pharmacographia*).

Medical Action and Uses.—Jalap and its resinous principle, convolvulin, act as local irritants, and, taken into the stomach, excite irritation of that organ, with nausea, vomiting, colic, and mucous, watery, and even bloody dejections, according to the dose. When given to dogs in excessive doses it has occasioned death, after which the gastrointestinal mucous membrane was found inflamed. Although it is said to produce analogous effects in these animals when rubbed into the skin, it is, on the other hand, denied that this effect takes place in man, and affirmed that the milk of nursing women is not rendered purgative by its use. So, too, convolvulin, which purges if taken into the stomach, has no such effect when it is injected into a vein or hypodermically. The experiments of Rutherford and Vignal led them to conclude that jalap is an hepatic stimulant of considerable power, rendering the bile more watery, but at the same time increasing the secretion of biliary matter. Its effect on the liver is, however, far less notable than its effects on the intestinal glands. Its medicinal virtues depend upon its being a hydragogue cathartic whose operation is not rendered less decided by the repetition of the medicine. Hence it is profitably employed for the removal of *dropsical effusions* from whatever cause they arise, the duration of its usefulness depending upon the nature of

the cause of the dropsy. It is usually associated with bitartrate of potassium for this purpose, and with calomel in congested states of the liver or spleen. It is to be commended in states of *constipation* attended with habitual dryness of the intestine, when it should be given in a dose of 2 or 3 grains (Gm. 0.10–0.20) in the morning, fasting, and followed within an hour by a draught of cool water. A grain or two of aloes given the night before renders its operation more certain, and is apt to promote the biliary secretion. It is not an anthelmintic, but a *vernifuge*, and is associated habitually with proper anthelmintic medicines.

Administration.—The purgative dose of jalap is from 15 to 20 grains (Gm. 1–1.30). Its powder should be thoroughly triturated with sugar and flavored with an aromatic oil. The resin is estimated to be from two to four times as strong as jalap. The syrup of rhubarb is said to completely dissolve it and to increase its efficiency.

JEFFERSONIA.—TWINLEAF.

Jeffersonia diphylla, Barton.

Nat. Ord.—Berberidaceæ.

Origin.—The twinleaf is an herbaceous, acaulescent perennial growing in woods in the Middle, Southern, and Western United States. The leaves are on long petioles composed of two obliquely ovate leaflets; the scape is about 10 inches (25 Cm.) high, bearing a white flower an inch broad, which has four fugacious sepals, eight spreading petals, and eight stamens, and produces an obovate capsule with many seeds. It flowers in April and May.

Description.—The rhizome is horizontal, knotty, beset with long, fibrous, and matted roots of a yellowish or dark-brown color, somewhat corrugated and transversely fissured; the bark is brown, of a resinous appearance, and has a bitter and acrid taste. The pale-yellowish wood is destitute of taste.

Constituents.—The rhizome was analyzed by E. S. Wayne (1855), and contains, besides the ordinary vegetable principles, tannin, precipitating ferric salts dark-green, a bitter principle and an acrid acid analogous to polygalic acid. F. F. Mayer (1863) states that the rhizome contains a small quantity of *berberine*, a larger proportion of a *white alkaloid*, and a considerable amount of *saponin*.

Medical Action and Uses.—No recent observations seem to have been made of the virtues of this plant. It is said to be diuretic, tonic, and expectorant in small, and emetic in large, doses. It has been compared to seneka.

JUGLANS, U. S.—BUTTERNUT-BARK.

Ecorce de noyer gris, Fr.; *Graue Walnussrinde*, G.

The inner bark of the root of *Juglans cinerea*, Linné (*J. cathartica*, Michaux, *J. oblonga*, Miller). Bentley and Trimen, *Med. Plants*, 247.

Nat. Ord.—Juglandaceæ.

Origin.—A handsome tree, 30 to 40 feet (9–12 M.) high, growing in forests and bottom-lands in Canada and the greater portion of the United States westward to Missouri and Arkansas. It has a brown, soft, but durable and easily-worked wood; the leaves are composed of about fifteen sessile, oblong-lanceolate, serrate, and underneath pubescent leaflets; the staminate flowers are in aments about 4 inches (10 Cm.) long; the pistillate flowers, to the number of about five, form a spike; the fruit is ovoid-oblong and viscid pubescent. The tree flowers in April and May, and ripens its fruit in September and October. The bark is collected in May and June, or, according to the Pharmacopœia, in autumn, and is deprived of its corky layer.

Description.—The liber, of which the medicinal article exclusively consists, is white when fresh, but rapidly turns yellow and deep-brown on drying. It is met with in commerce in flat or in curved pieces, about $\frac{1}{2}$ or $\frac{3}{4}$ inch (3 or 6 Mm.) thick, and varying in length, both ends being usually cut off obliquely. The outer surface has often thin patches of cork adhering; the inner surface is smooth and striate. The tangential arrangement of the brownish bast-fibres, alternating with white parenchyma and crossed by the numerous fine white medullary rays, gives the cross-section a delicately checkered appearance. The bark breaks readily with a short fracture both transversely and longitudinally. It has a feeble odor and a bitter somewhat acrid taste. If collected in April it has a sweetish, insipid taste, and is said to be less active.

Constituents.—The bark has been examined by Thiebaud (1872) and by Dawson

(1874). The latter found a little tannin, trace of volatile oil, a little resin, and 14 per cent. of fixed oil; also a volatile acid, called by Thiebaud *juglandic acid*, but which is doubtless identical with the *nucin* of Reischauer and Vogel (1856), discovered by them in the pericarp and leaves of *Juglans regia*, *Linné*. Nucin, or *juglone*, which seems to have the composition $C_{36}H_{12}O_{10}$, has an acrid taste, an acid reaction to test-paper, and is sparingly soluble in water, more so in alcohol, and readily so in ether, chloroform, and carbon bisulphide; it crystallizes as orange-yellow needles, and acquires, with alkalis and with the alkaline borates and phosphates, a handsome purple color. If the properties of the bark depend wholly or in part on this principle, it is easily explained why continued boiling should render it less efficacious. Tanret and Villiers (1877) obtained from the leaves of the European walnut a crystallizable non-fermentable sugar, *nucit*, $C_6H_{12}O_6 \cdot 2H_2O$, and Tanret (1876) reported having isolated a crystallizable alkaloid. According to Sestini, the root of the European walnut contains *glycyrrhizin*.

Allied Plants.—*JUGLANS REGIA*, *Linné*, *English walnut*. The green pericarp (Cortex fructus juglandis) and the leaves (Folia juglandis, *P. G.*) have a peculiar odor and a somewhat astringent and bitter taste. The young fruit of both species is used for pickles, and when ripe the kernels yield a bland and drying fixed oil known as *nut oil*; it is greenish or pale-yellow, congeals like lard at about $-18^{\circ} C.$ ($0^{\circ} F.$), and acquires a red color with nitric acid and a dark-brown one with a mixture of nitric and sulphuric acids. Similar oils are contained in the butternut and in the seeds of *Juglans nigra*, *Linné*. *Carya olivæformis*, *Nuttall* (*pecan-nut*), and other species of *Carya*, the various *hickory-nuts*.

Off. Prep.—Extractum juglandis, *U. S.*

Medical Uses.—Butternut is employed medicinally in the form of the official extract alone, which, according to Rutherford's experiments, is a "moderately powerful hepatic and a mild intestinal stimulant."

Juglans regia, or English walnut, was once reputed to be a remedy for *scrofula*, and in France about 1840 it was actively advertised for this purpose by Négrier and others, but its credit was not sustained. The leaves are a popular cure for *leucorrhæa* when used in decoction as an injection, and in other mucous profluvia internally. An extract of the leaves has been claimed by Luton to be curative of tubercular *meningitis* (*Études de thérapeutique*, 1882); and his reports are more or less sustained by those of Tanret, Meslier, and Guénot (*Bull. de therap.*, tom. xc. xci.), but they have not been confirmed by ulterior observation. *Juglans nigra*, or black walnut, says Griffith, has a styptic and acrid bark, seldom used except in dyeing. The rind of the unripe fruit is said to remove *ringworm* and *tetter*, and a decoction has been given as a *vermifuge*. In France the leaves, the rind of the fruit, and the inner bark of *J. regia* have long been in popular and medical use for repressing the *mammary secretion*, for curing *ulcers* of all parts, including the uterus, for treating *diarrhæa*, *leucorrhæa*, *ulcerated sore mouth*, affections of the *tonsils*, *uterine hæmorrhage*, etc. In 1853, Pomeyrol treated with singular success *carbuncle* and *malignant pustule* by the simple application of the fresh leaves of black walnut frequently renewed (Cazin, *Plantes médicinales*, p. 640). A decoction of black-walnut leaves was also advantageously substituted for a complex and perturbative treatment of *diphtheria* by Dr. Curtis (*Boston Med. and Surg. Jour.*, March, 1881, p. 226).

In England a preparation known as "spirit of walnut" is made by distilling alcohol from fresh walnuts, and is stated to be very efficient in "hysterical vomiting, the vomiting of pregnancy, and even for cerebral vomiting" (Mackey, *Practitioner*, xxi. 401).

JUGUBA.—JUJUBE-BERRIES.

Jujube, Fr.; *Brustbeeren*, *Judendornbeeren*, G.

The fruit of *Zizyphus vulgaris*, *Linné*, and *Z. Lotus*, *Lamarck*.

Nat. Ord.—Rhamnaceæ.

Origin.—The jujube-shrubs are indigenous, the former to Asia Minor and Syria, the latter to Northern Africa, and are cultivated in Southern Europe. They are shrubby or sometimes tree-like, and have alternate ovate and serrate three-nerved leaves, at the base with two prickly afterward spiny stipules. The fruit is a two-celled and two-seeded, or by abortion one-celled and one-seeded, drupe.

Description.—Jujubes are roundish oblong and nearly an inch (25 Mm.) long, but obtained from the second species are subglobular and about $\frac{3}{8}$ inch (15 Mm.) long; they are bright-red, or after drying brownish-red, wrinkled, with a thin leathery pericarp, a soft mucilaginous and sweet sarcocarp, and an ovate, acute, wrinkled, and usually one-seeded endocarp.

The fruits of *Ziz. Jujuba*, *Lamarek*, a slender East Indian tree, and of several other species, possess similar properties.

Constituents.—Jujubes contain mucilage and sugar. The bark contains tannin.

Pharmaceutical Uses.—*MASSA DE JUJUBIS*—Jujube paste, *E.*; *Pâte de jujubes*, *Fr.*—is prepared by extracting 5 parts of jujubes with sufficient water to obtain 35 parts of infusion, in which are dissolved gum-arabic 30 parts and sugar 20 parts; the solution is evaporated, 2 parts of orange-flower water added, kept slowly boiling for 12 hours, and then poured into moulds.—*P. Cod.* In the jujube paste, as sold in the United States, the jujubes are usually omitted.

Medical Action and Uses.—In the native countries of the jujube its fruit is ranked with figs and raisins and other more or less saccharine and acidulous fruits which are used in tisanes for acute irritations of the *throat* and *air-passages*, much as in this country we employ the syrup and jelly of currants, blackberries, etc. The so-called jujube paste seldom contains any of the fruit, but is made of gum-arabic and sugar, with some flavoring ingredient and a variable proportion of opium.

JUNIPERUS, U. S.—JUNIPER.

Fructus juniperi, P. G.; *Baccæ*, s. *Galbuli juniperi*.—Juniper-berries, *E.*; *Genièvre*, *Fr.*; *Wachholderbeeren*, *Kaddigbeeren*, *G.*

The fruit of *Juniperus communis*, *Linné*. Woodville, *Med. Bot.*, t. 6; Bentley and Trimen, *Med. Plants*, 255.

Nat. Ord.—Coniferae, Cupressaceæ.

Origin.—Juniper is indigenous to the northern hemisphere, and is found in North America from the Southern United States to Canada and Greenland, and westward to the

Pacific, throughout Asia from the Himalayas northward, in Northern Africa, and throughout Europe. It is commonly a shrub 4 to 6 feet (1.2–1.8 M.) high, sometimes arborescent, or in the variety *alpina* (*Jun. nana*, *Willdenow*), prostrate and spreading, the latter being met with in Arctic and mountainous localities. The numerous leaves are persistent, spreading, in whorls of three, linear and sharp-pointed; the staminate flowers are arranged in short ovate catkins; the pistillate form a short cone consisting of about five imbricate whorls, each of three scales. Three naked ovules are situated at the base of the upper whorl, and, after fructification, these scales enlarge, coalesce, become fleshy, and ultimately enclose the seeds, forming the official berry-like galbulus, which ripens during the second year. The trade is mostly supplied from Southern and Central Europe; in 1882 the United States imported about 170,000 pounds (1187 packages).

Description.—Juniper-berries are nearly globular, about $\frac{1}{8}$ inch (8 Mm.) in diameter, dark-purplish, and covered with a bluish-gray bloom; the short stalk at the base contains one or two whorls of the small scales, and the apex is marked by three radiating furrows, which are surrounded by ridges enclosing a triangular space. The three, or by abortion one or two, bony seeds are ovate in shape, triangular above, have six to ten large oil-sacs on their surface, and are imbedded in a brownish pulp which likewise contains oil-cells. Juniper-berries have an aromatic somewhat balsamic odor and a sweet, terebinthinate, bitterish, and slightly acid taste.

Constituents.—Juniper-berries were analyzed by Trommsdorff (1822), Nicolet (1831), Steer (1856), and Donath (1873). They contain from $\frac{1}{2}$ to $2\frac{1}{2}$ per cent. of volatile oil (see *OLEUM JUNIPERI*), about 30 per cent. of sugar, resins amounting to 10 per cent., 4 of protein compounds, fat, wax, formic and acetic acids, malates, and *juniperin*, which is light-yellow, slightly soluble in water, freely so in alcohol and ether, and with a golden-yellow color in ammonia. Ritthausen (1877) obtained from juniper-berries, containing 10.77 per cent. of water, only 14.36 per cent. of sugar, 3.77 of ash, and 31.60 of cellulose.

Pharmaceutical Uses.—*INFUSUM JUNIPERI*.—Infusion of juniper-berries, *E.*; *Tisane de genièvre*, *Fr.*; *Wachholderbeeren-Aufguss*, *G.*—Bruised juniper-berries a troy-ounce, boiling water a pint; macerate for an hour in a covered vessel, and strain.—*U. S. P.* 1870.

FIG. 168.

Juniperus communis, *Linné*: a, fertile catkin and longitudinal section; b, galbulus and transverse section; c, seed and longitudinal section, magnified.

Other Products of Juniper.—LIGNUM JUNIPERI, *Juniper-wood*, is used in Europe as an alterative and diaphoretic in diseases of the skin and rheumatic affections. RESINA JUNIPERI, the resinous exudation found in the bark, is sometimes called *German sandarac*.

SUCCUS JUNIPERI INSPISSATUS, *P. G.*, s. Roob juniperi.—Extract of juniper-berries, *E.*; Rob de genièvre, *Fr.*; Wachholdermus, *G.*—An infusion is made of bruised juniper-berries by macerating with water (hot water, *P. G.*), filtering, and evaporating to the consistence of a soft extract. Fresh juniper-berries yield about 32 per cent. of this extract, which is of a dark-brown color and of a sweet and aromatic taste.

Off. Prep.—Oleum juniperi, *U. S.*

Medical Action and Uses.—Juniper is stimulant, stomachic, carminative, diuretic, and emmenagogue. It communicates a special odor to the urine. It is much used in the treatment of *dropsies*, and especially of scarlatinous and other forms of dropsy due to tubular obstruction of the kidneys. (Juniperi contus., Potassii bitart. āā ʒss; Aquæ fervent. Oj. Make an infusion, to be used in divided doses during 24 hours. Acetate of potassium may be substituted for the bitartrate in this formula, but in half the quantity. The diuretic virtues of the infusion may be increased by the addition of parsley, buchu, horse-radish, etc.) In chronic catarrhal affections of the *urinary passages* juniper is useful, and also when sabulous matter is habitually voided. As an anodyne for painful *swellings*, and generally for *local pains*, bruised juniper-berries are sometimes used, and fumigations made by throwing the berries upon hot coals may be employed to relieve *rheumatic pains*.

JUNIPERUS VIRGINIANA.—RED CEDAR.

Cèdre de Virginie, *Fr.*; *Virginische Ceder*, *Rothe Ceder*, *G.*

The tops of *Juniperus virginiana*, *Linné*.

Nat. Ord.—Coniferae, Cupressææ.

Origin.—Red cedar is shrubby, or is more frequently a tree 50 or sometimes 90 feet (15–27 M.) high, growing in sterile or rocky soil in Canada and the United States, south to the Mexican Gulf and westward to Eastern Texas, Nevada, and British Columbia. It has a compact, close-grained, very durable, reddish, and odorous wood, and horizontal branches, the older leaves spreading and awl-shaped, the young leaves appressed and imbricate, and a small non-pendulous fruit. The young branches, on which the leaves are still appressed, are collected for medicinal purposes.

Description.—The branchlets resemble *savine*, are about 1 inch (25 Mm.) long, and of a quadrangular appearance from their four rows of scale-like leaves, which are ovate-lanceolate, obtuse, or rather acute, appressed, and imbricated. They have a longitudinal furrow on the back, which gradually deepens toward the base, where there is contained a circular or oblong gland. They have a not unpleasantly terebinthinate odor and an aromatic, bitterish, and somewhat acrid taste.

Constituents.—Red cedar was analyzed by W. J. Jenks (1842), who found it to contain volatile oil, resin, fat, tannin, and other common constituents of plants. *Oil of red cedar*, distilled from the wood, was examined by Walter (1842). On exposing it to cold, expressing the coagulated mass, and recrystallizing the solid portion from alcohol, *cedren camphor*, $C_{15}H_{26}O$ (Gerhardt), was obtained, which has an aromatic odor and a slight taste. The liquid portion, after rectification and distillation over potassium, is *cedren*, $C_{15}H_{24}$ (Gerhardt), which is colorless, of specific gravity 0.98, boils at $237^{\circ} C.$ ($458.6^{\circ} F.$), and has an aromatic odor differing from that of the camphor, and an aromatic afterward pepper-like taste.

Medical Action and Uses.—The leaves of red cedar are said to possess in some degree the qualities of *savine*, but definite information upon the subject is wanting so far as their internal operation is concerned. An ointment prepared with them is employed as a dressing to maintain the discharge of *suppurating surfaces*. The fumes given off by the burning shavings of the dried wood are reputed to be useful in muscular *rheumatism*. An infusion of the berries is reported to be diuretic when cold and diaphoretic when hot, and the small gall-like excrescences found on the branches are eaten as an *anthelmintic* medicine.

KAIRINA.—KAIRINE.

Kairine, *Fr.*; *Kairin*, *G.*

The hydrochlorate of an artificial alkaloid prepared from chinoline. Formula $C_{10}H_{13}NO.HCl.H_2O$; molecular weight 217.4.

Preparation.—Chinoline (page 472) is treated with fuming sulphuric acid; the resulting *methylsulphonic acid* is fused with caustic soda, when *oxychinoline* is obtained, the potassium compound of which, on being treated with methyl iodide, yields *oxymethylchinoline*, and this, with tin and hydrochloric acid, yields *oxyhydromethylchinoline*; by precipitating this from its ethereal solution with hydrochloric acid gas, *kairine* is yielded. The order of treatment may vary (*Ber. Chem. Ges.*, 1883, 712). The salt was prepared by O. Fischer and C. Bedall (1881).

Properties.—The pure alkaloid is sparingly soluble in water and readily soluble in alkalies, benzol, hot alcohol, and methyl alcohol; it crystallizes from ether in tabular and from alcohol in prismatic, rhombic colorless crystals. Its alcoholic solution yields with ferric chloride a dark-brown or black-brown color and precipitate; with ferrous sulphate a transient dark-red color, and in concentrated solutions a dingy-colored precipitate; and with potassium ferrocyanide in acid solutions a nearly colorless voluminous precipitate, which crystallizes from boiling water in bluish-green needles.

The hydrochlorate (*kairine*) is readily soluble in water, and on evaporating this solution over sulphuric acid yields colorless glossy monoclinic tabular crystals, which at 110° C. (230° F.) lose 8.27 per cent. of water. The commercial salt is a grayish or yellowish crystalline powder, of a slight phenol-like odor, and of a saline, bitter, and somewhat aromatic taste. Klie (1883) found it nearly insoluble in ether, insoluble in chloroform, carbon disulphide, and oil of turpentine, but soluble in 7.5 parts of cold and 1.5 parts of boiling water, in 19 parts of alcohol, and in 15 parts of glycerin. The solution is colored dark-purple by potassium bichromate, and is precipitated by the group reagents for alkaloids. The platinum double salt crystallizes in prisms, and on boiling with water turns red. *Kairine* burns upon platinum-foil with a smoky flame.

Allied Compounds.—KAIRINE A, $C_{11}H_{15}NO.HCl$, is oxyhydroethyl-chinoline hydrochlorate, crystallizes in white prisms, and resembles in its properties the preceding salt.

KAIROLINE is the sulphate of tetrahydromethyl-chinoline, $C_{10}H_{13}N$.

KAIROCOLL, $C_{11}H_{11}NO_2$, dissolves sparingly in water, but readily so in alcohol and ether.

Medical Action and Uses.—In 1882, Prof. Filehne of Erlangen announced that the newly-discovered muriate of *kairine* reduced the temperature of fever to the normal degree without occasioning any of the unpleasant effects of other anti-pyretics. Taken by healthy adults in doses of from 15 to 20 grains (Gm. 1–1.60), it was said not to produce any appreciable change in the temperature nor to cause headache, buzzing in the ears, vomiting, etc. Sick or feeble persons who took 15 grains (Gm. 1) every 2 hours were apt to present a cyanotic discoloration. The action of the last-named doses did not last more than 3 hours, and of 8 grains more than 2½ hours; and as their effects passed off the patients experienced a chill that sometimes continued until the return of the normal temperature. Single doses of from 5 to 15 grains (Gm. 0.30–1) reduced the temperature from ½ to 2° C., or even more; and when a dose was repeated before the action of the previous one had passed off, the temperature might be depressed to 37° or 36.5° C. (98.6 or 97° F.). These observations were confirmed by Hallopeau (*Bull. de therap.*, civ. 241). The primary action of an efficient dose began about 25 minutes after it had been taken. The fall of temperature was generally accompanied by copious perspiration until the lowest point was reached. According to Filehne, during this process the febrile patient is extremely comfortable—in pneumonia, for example, he ceases to suffer from pain or oppression—but as the action of the medicine subsides the fever returns, and with it the local symptoms. While the patient is taking the medicine the urine acquires a green color, but contains neither albumen nor sugar. An objection early made to the medicine was the necessity of continuing to administer it at regular intervals of about 2½ hours, day and night, for unless this is done the fever soon returns to its former height (*Centralblatt f. Therapie*, i. 31, 273).

Other observers have more or less confirmed or modified these statements. In Vienna, Drasche, in treating *pneumonia* according to Filehne's method, found that the larger doses given in rapid succession sometimes induced collapse, with cardiac failure and bilious vomiting—symptoms that remind one of poisoning by digitalis. Such effects were also observed in *phthisis*. In *erysipelas* of the face its virtues were not evident, and in *typhoid fever* it did not aggravate the diarrhœa, while it seemed to suppress the brain symptoms and keep the tongue moist (*ibid.*, i. 277). Freimuth and Poelchen used the medicine in *relapsing fever*, and decline to recommend it for that disease, and in view of its disturbing the stomach suggested that it be administered by enema or hypodermically (*ibid.*, i. 279). Seifert states that his experience with the medicine in *pneumonia* did not confirm Filehne's reports, and points out that a fall in the pulse-rate and temperature is by no means

a constant effect of the medicine (a statement also made by Hoffer); that the alleged solace of the pain in the side, of the dyspnœa, etc., did not occur, but that vomiting did, and that profuse sweating and a state of alarming collapse were induced by the medicine. He concludes that he will not again prescribe kairine in pneumonia (*ibid.*, p. 280). Reigel arrived substantially at the same conclusions (*ibid.*, p. 416); and Hoffer adds that not only is the action of the medicine transient, but that tolerance is very soon established (*ibid.*, p. 421). Pribram states that in certain healthy persons even small doses of it have occasioned a thready pulse, nausea, and a cyanotic complexion, and that it has no influence upon either the duration or the issue of pneumonia (*ibid.*, p. 417). On the other hand, Purjesz agrees pretty nearly with Filehne (*ibid.*, p. 419); Guttmann gives to kairine the preference over all other anti-pyretics in certainty and promptness of action; and Riess is of the same opinion (*ibid.*, p. 419, 420). Elsewhere than in Germany the reports concerning this medicine agree, more or less, with the above in essential particulars (compare Shattuck, *Boston Med. and Surg. Jour.*, Nov. 1883, p. 415; Draper, *ibid.*, p. 417; Crook, *Med. News*, xlv. 326), and especially that the medicine is an efficient anti-pyretic; but none of them prove it to bear the marks of a true remedy, curing disease "*cito, tuto, et jucunde.*"

Two inferences may be drawn from the statements of these observers: 1, That there is no agreement as to the clinical effects of the medicine; and 2, that no proof is given that it either shortens the duration or lessens the mortality of any disease in which it has been used. In this respect, then, it stands in the same line with various other preparations that lower the temperature and the pulse-rate. Like them, it may be considered as a physiological agent rather than a medicine, at least in febrile affections—*i. e.* an agent that illustrates the relation of certain functions, but not as a remedy for the diseases in which it has thus far been used.

Filehne recommends that the primary dose of kairine should not exceed 4 or 5 grains (Gm. 0.25); that it should be repeated and increased at intervals of 2 or 3 hours, according to its influence on the temperature, to 8 or even 15 grains (Gm. 0.50–1); and that when the desired subsidence is obtained the dose should be gradually reduced. Guttmann prescribes 15 grains (Gm. 1) hourly for 2 hours, and after that 7 or 8 grains (Gm. 0.50) every hour until the desired reduction of temperature is secured; after which 3 or 4 grains (Gm. 0.25) should be given at like intervals to prevent reaction. If a chill threatens, an additional dose like the last should be administered. Riess went so far as to give hourly doses of from 20 to 50 grains (Gm. 1.50–3.50); but as the latter dose caused grave symptoms, it was only once administered (*Edinb. Med. Jour.*, xxix. 850). It is most conveniently administered in wafers or capsules, to avoid its bitter saline taste and its acrid impression on the fauces.

KALMIA.—MOUNTAIN LAUREL.

Calico-bush, *Spoon-wood*, E.; *Kalmie*, Fr., G.

The leaves of *Kalmia latifolia*, Linné.

Nat. Ord.—Ericacææ, Ericineæ.

Origin.—This shrub is found in Canada, and in the United States south to Florida and Alabama and west to Wisconsin, Kentucky, and Arkansas. It is abundant in many places, preferring woods on rocky hills and damp soil, and is usually about 6 feet (1.8 M.) high, but sometimes tree-like and 30 or 40 feet (9–12 M.) high. The wood is yellowish, close-grained, very hard and strong; the elegant but inodorous flowers appear in May and June, are in dense racemose corymbs, and have a rose-red or whitish subcampanulate corolla, which, in the lower part, is furnished with ten cavities holding the ten anthers until they begin to shed their pollen. The Indians are said to have made spoons from the wood.

Description.—The leaves are alternate, 2 or 3 inches (5–8 Cm.) long, petiolate, coriaceous, oval-lanceolate, or elliptic, entire, acute at both ends, smooth and green on both sides. They are without odor and have an astringent and bitterish taste.

Constituents.—Charles Bullock (1848) proved the leaves to contain tannin, a principle resembling manuit, an acrid principle, resin, gum, and other common constituents of plants. Kennedy (1875) isolated *arbutin*, which appears to be present in smaller proportions than in *uva ursi*.

Allied Plants.—*KALMIA ANGUSTIFOLIA*, Linné, known as *sheep-laurel*, *sheep-poison*, and *lamb-kill*, has opposite or ternate linear-elliptic leaves, which are 1 or 2 inches (2 to 5 Cm.) long, and

whitish or brownish beneath. The small flowers are of a deep-crimson color (Meehan, *Nat. Flowers* [2], ii. 181).

KALMIA GLAUCA, *Aiton*, *Swamp-laurel*, has pale-purple flowers and subsessile lanceolate leaves, which are glaucous beneath, about an inch (25 Mm.) long, and opposite on the two-edged branches.

ANDROMEDA MARIANA, *Linneé*, or *stagger-bush* (Meehan, *Native Flowers*, ii. 185), is likewise reported to be poisonous to lambs and calves. It is a shrub 2 or 3 feet (60 or 90 Cm.) high, produces clusters of white, nodding, ovate-cylindrical flowers, and has thick but deciduous, smooth, oval or oblong, entire leaves, about 2 inches (5 Cm.) long. It grows in the seaboard States from New England to Florida and westward to Tennessee and Arkansas.

XYDENDRUM ARBOREUM, *De Candolle*, s. *Andromeda arborea*, *Linneé*, *sorrel tree* or *sour-wood*, is about 40 feet (12 M.) high. The leaves are deciduous, oblong-lanceolate, pointed, serrulate on the margin, and nearly smooth. They resemble peach-leaves in shape and have a refreshing acidulous taste. The tree grows in the Alleghanies and westward to Arkansas.

All the species named above belong to North America.

Medical Action and Uses.—The leaves and berries of the mountain-laurel have long been known to be poisonous, but their action has chiefly been learned through the effects produced in man by eating the flesh of partridges (*Tetrao umbellus*) that have fed upon the berries. From a number of cases observed or collected by Dr. Jacob Bigelow he prepared (1857) the following summary of the symptoms of this poisoning: The flesh of the bird "acts as a direct sedative poison, impairing the functions of the brain, and, in connection, those of the digestive and circulatory systems. The cerebral symptoms, in a majority of the cases, have been vertigo, loss of sight, timidity, and in bad cases general loss of the power of sensation and voluntary motion. Respiration has been slow, sometimes to a great degree. In the circulatory system there has been syncope, feeble and sometimes irregular action of the heart, weak, slow, and sometimes imperceptible pulse, cold surface, and pale or livid complexion. In the digestive system there are oppression, nausea with a tendency to vomit, and in many cases pain in the abdomen, extending through to the back. In more rare cases pain has been felt in the head and limbs. . . . The poison of the partridge has never, to my knowledge, proved fatal." One of the most recent cases was published by Dr. Homans in 1871, and answers, trait for trait, to the summary given above. The connection of these symptoms with laurel-poisoning has been questioned, and they have been attributed to the partial putrefaction of the bird's meat when it was eaten. But as they are identical with the effects observed by Stabler (*Am. Jour. of Phar.*, x. 241) in himself after taking a strong decoction of laurel-leaves, there need be no doubt of their having been referred to their true source. The medicinal value of this plant is almost entirely conjectural. The bruised leaves, and also a decoction, are said to have been applied to certain *cutaneous eruptions*, and it is added that alarming symptoms have sometimes resulted, probably because the skin was not whole. It might be profitable to test their efficacy in neuralgic and other local pains by applying them in the same manner.

Oxydendron arboreum is said to be diuretic and laxative. A semi-solid extract, in doses of from 3 to 12 grains three times a day, is alleged to have removed dropsical effusions (Clendennin, *Med. Record*, xxiii. 707).

KAMALA, U. S., Br., P. G.—KAMALA.

Rottlera, U. S. 1870; *Glandulæ rottleræ*.—*Kameela*, *Kamala*, Fr., G.

The glands and hairs obtained from the capsules of *Mallotus* (*Echinus*, *Baillon*) *philippinensis*, *Müller Arg.*, s. *Croton philippense*, *Lamarck*, s. *Rottlera tinctoria*, *Roxburgh*. Bentley and Trimen, *Med. Plants*, 236.

Nat. Ord.—Euphorbiaceæ.

Origin.—The kamala grows wild in Australia, Eastern China, India, Southern Arabia, and Abyssinia, and in most of the islands lying between these countries from the Philippines westward. It is a large shrub or small tree, with petiolate, ovate, acute, and entire leaves, and produces globular tricoecous three-seeded capsules, from which the glands are obtained by rubbing and sifting in baskets.

Description.—Kamala is a fine granular, mobile powder of a brick-red color, somewhat resinous appearance, inodorous, and nearly tasteless. It is with difficulty mixed with water, imparts to boiling water only a yellow tinge, but a deep-red color to alkaline solutions, alcohol, ether, chloroform, and benzol. When thrown into a flame it burns similar to, but less rapidly than, lycopodium, and when heated in a crucible it leaves a small amount of ash, which weighs from pure kamala 1.37 per cent. (*Pharmacographia*).

Examined under the microscope, the glands are seen to be depressed-globular, and to consist of a thin transparent membrane enclosing a yellowish mass in which are imbedded many club-shaped vesicles radiating from a common centre, and containing a red substance; this structure becomes more apparent after treating the glands with potassa and pressing them between glass. The glands are always mixed with colorless stellately-arranged simple hairs, but fragments of leaves and stems should not be present. When heated in a crucible to redness, kamala should leave not more than 8 per cent. (*U. S.*; 6 per cent. *P. G.*; at most 10 per cent. *Br.*) of ash, having a gray, not a red, color.

Constituents.—Pure kamala contains only between .5 and 3.5 per cent. of moisture, and yields to ether, alcohol, amyl alcohol, glacial acetic acid, or carbon disulphide about 80 per cent. of resin, which is also soluble in alkalis, but not in benzin, and whose alcoholic solution is colored dingy-green by ferric chloride (Flückiger). Leube (1860) analyzed a sample of kamala which yielded nearly 29 per cent. of ash, 47.6 of resin, and 19.7 of other soluble matters, consisting of citric, oxalic, and tannic acids, gums, etc. Cold alcohol dissolved a resin, $C_{15}H_{15}O_4$, fusible at $80^{\circ}C.$ ($176^{\circ}F.$), and left a more sparingly soluble resin, $C_5H_{12}O_5$, melting at $191^{\circ}C.$ ($376^{\circ}F.$). Both resins are brittle, red-yellow, soluble in alkalis with a red color, not altered by dilute acids, and when treated with nitric acid yield oxalic acid. Leube could not obtain Anderson's *rottlerin*, $C_{22}H_{20}O_6$ (1855), which crystallized from the concentrated ethereal tincture in yellow silky needles. Groves (1872) ascertained that it is easily modified by exposure to air, and is consequently obtained only from the recent drug. Flückiger subsequently observed that on being fused with potassa rottlerin yields *paraoxybenzoic acid*. Anderson's *resinous coloring matter* has the composition $C_{30}H_{30}O_7$, melts at $100^{\circ}C.$ ($212^{\circ}F.$), is easily soluble in alcohol and ether, and yields with lead acetate an orange-colored precipitate. By treating kamala with boiling alcohol, and cooling, amorphous floccules of the composition $C_{20}H_{34}O_4$ are obtained, which are sparingly soluble in cold alcohol and ether, and are not precipitated by lead or silver salts.

Kamala, magnified 190 diameters.

Allied Drug.—*WARS, WARRAS, OR WURRUS.* This name, which is the Arabian for saffron, has occasionally been given to kamala, but in Eastern Africa is given to a distinct drug of unknown origin, but used for dyeing, and medicinally like kamala. It forms a rather coarse powder of a deep-purple color and slight odor, becomes black at the temperature of a water-bath, yields from 6 to 12 per cent. of ash, and under the microscope is seen to consist of cylindrical or subconical glands enclosing oblong vesicles arranged in three or four tiers; the glands are mixed with rather long, simple hairs.

Medical Action and Uses.—Kamala has long been employed in Hindostan as a remedy for *tania*. It does not occasion much nausea, colic, or purging. British soldiers in India, it is said, often apply for a dose of the medicine, "after which they invariably part with the worm in the course of a few hours, and then go on with their military duty as if nothing had happened." In general, the parasite seems to have been discharged dead. The medicine appears to be equally efficient in removing *lumbricoid* worms and rectal *ascarides*.

The dose of powdered kamala is 1 or 2 drachms (Gm. 4–8). To prevent its griping, hyoseyamus may be associated with it. A saturated tincture has been found efficient in doses of from 1 to 3 fluidrachms (Gm. 4–12), diluted with cinnamon-water, or the extract produced by evaporating the tincture may be employed. The dose of either preparation should be repeated several times at intervals of about 3 hours.

KINO, *U. S.*, *Br.*—KINO.

Gummi (s. Resina) Kino.—Kino, Fr., G.

The inspissated juice, obtained from incisions made in the trunk, of *Pterocarpus Mar- subup. Roxburgh.* *Corom.*, plate 116; Bentley and Trimen, *Med. Plants*, 81.

Nat. Ord.—Leguminosæ, Papilionacæ.

Origin.—The kino tree, called *baja* in Bengal, is 60 to 80 feet (18–24 M.) high, has numerous spreading branches, a red inner bark, unequally pinnate deciduous leaves, yellowish flowers in loose racemes, and nearly orbicular and winged pods, which contain a single kidney-shaped seed. It is indigenous to India and Ceylon, and on incisions being

made through the bark yields a red juice, which is dried by exposure to the air and sun. *Pter. indicus*, *Willdenow*, a native of Southern India and of the Philippine Islands, yields kino of a fetid odor. 7783 pounds of kino were imported into the United States in 1881.

Description.—East India or Malabar kino is met with in small, angular, dark-red or brownish-red, glistening, and brittle pieces, which in thin layers are transparent and of a ruby-red color, and tinge the saliva deep-red; it softens between the teeth, is inodorous, and has a very astringent and sweetish taste. It is partly soluble in cold water, leaving a flocculent residue, and is entirely soluble in alcohol and nearly insoluble in ether. The solutions have an acid reaction: the aqueous solution is precipitated green-black by ferric salts, gray-purplish by lead acetate, light-brown by tartar emetic, and reddish by mercuric chloride. The solution in diluted alcohol is apt to gelatinize.

Constituents.—By treating kino with ether Eissfeldt (1854) obtained a minute quantity of *pyrocatechin*. The products of the dry distillation of kino contain a larger quantity of the same substance, which may be obtained pure by subliming in a benzoic acid apparatus. Kino contains no *catechuic acid*, but its tannin, *kino-tannic acid*, seems to be chemically related to catechu tannin, since it yields similar decomposition-products; but it has not yet been obtained in a pure condition, being accompanied by red coloring matter, and, according to Hennig (1853), by a pectin compound from which it cannot easily be freed. The aqueous solution of the acid gives with pure ferrous salts when carefully neutralized a violet color, and with ferric salts a blackish-green one. Mineral acids and many metallic salts produce precipitates; hot nitric acid converts it into oxalic acid. In solution it is darkened by alkalies, and when treated with fusing potassa it is decomposed into *protocatechuic acid* and *phloroglucin*. On exposure to air the aqueous solution yields a red precipitate, slowly at the ordinary, more rapidly at the boiling, temperature; this is *kino-red*, an amorphous, tasteless mass, the alcoholic solution of which has a slight acid reaction. *Kino-red*, $C_{28}H_{22}O_{11}$, is also produced by heating *kinoïn* to 130° C. (266° F.). This compound was obtained by Etti (1879) by boiling kino with diluted hydrochloric acid and agitating the clear liquid with ether; it forms white crystals, the solution of which in water becomes red with ferric chloride. The compound which yields pyrocatechin and gallic acid was obtained by Flückiger from Australian, but not from Malabar, kino. Kino yields about 1.3 per cent. of ash.

Other Varieties of Kino.—AFRICAN or GAMBIA KINO exudes naturally from *Pter. erinaceus*, *Poir.*, of Western Africa, and agrees with the Bengal kino in behavior; it is not an article of commerce.

AUSTRALIAN or BOTANY BAY KINO is usually referred to *Eucalyptus resinifera*, *Smith* (*Myrtaceæ*), but F. von Mueller sent exudations from sixteen different species to Wiesner (1871), who found the products of *E. rostrata*, *Schlechtendal*, *E. corymbosa*, *Smith*, *E. piperita*, *Smith*, and of some others, to agree well with Malabar kino, while the exudation of *E. resinifera*, *E. gigantea*, *Hooker*, and others contains much gum, which is colored red by a kino-like substance. A kino-like substance is occasionally obtained from *E. globulus*, *Labillardière*.

BENGAL or PALAS KINO, *Butea gum*, from *Butea frondosa*, *Roxburgh* (*Leguminosæ*), is in dark ruby-colored tears and fragments, of which only about one-half or less is soluble in hot alcohol, the remainder being mucilaginous matter. According to Eissfeldt, it does not contain pyrocatechin, but yields this compound on dry distillation. When incinerated, *Butea gum* leaves about 1.8 per cent. of ash.

JAMAICA, WEST INDIAN, or CARACAS KINO, from *Coccoloba uvifera*, *Linneé*, or *sea-side grape* (*Polygonaceæ*), is obtained by boiling the wood and bark and evaporating the decoction. It resembles Malabar kino in appearance, but is of a brown tint, less glossy, and has a bitterish rather than a sweetish taste; it is soluble in both alcohol and water to the extent of about 90 or 93 per cent. The tannin of this kino seems to be closely related to, if not identical with, that of the official article. The plant named is a large tree of the West Indies and Southern Florida, and has a heavy, hard, and durable violet-brown wood. Whether the wood of *Coccoloba floridana*, *Meissner* (*C. parvifolia*, *Nuttall*), or *pigeon plum*, of Southern Florida, may yield kino has not been ascertained.

Off. Prep.—Pulv. catechu comp., Pulv. kino comp., *Br.*; Tinctura kino, *U. S.*, *Br.*

Medical Action and Uses.—This medicine is more lenitive than other astringents, in consequence, probably, of the pectin it contains. Its modified astringency renders it in some degree a local tonic. It is chiefly used in the treatment of *diarrhœa* and of that form of gastric disorder known as *pyrosis*. In the former it may be profitably employed when pure astringents would be too irritating, and is generally associated with opium, as it also should be in the treatment of water-brash. It has sometimes been given with apparent advantage to check *sweating* in phthisis, urination in *diabetes*, and bleeding in *menorrhagia*. Its solution may be used as an injection in *diarrhœa*, *dysentery*, and *leucorrhœa*, as a dressing for flabby *ulcers*, and as a gargle in ulcerated *sore throat*. In powder

it has been employed as a *hæmostatic*. But as a local application it is inferior to other astringents, and especially to tannin.

Kino may be prescribed in powder in the *dose* of from 10 to 20 grains (Gm. 0.60–1.30). An infusion may be made with 120 grains (Gm. 8) of kino in 8 fluidounces of boiling water. When cool it should be strained and given in doses of 1 or 2 tablespoonfuls. Owing to the tendency of its gummy matter to coagulate, it is less eligible than catechu as an ingredient of chalk mixture.

KRAMERIA, U. S.—RHATANY.

Krameria radix, Br.; *Radix ratanhiæ*, P. G.; *Radix ratanhæ*.—*Rhatany-root*, E.; *Ratanhia*, Fr.; *Ratanhawurzel*, G.

The root of *Krameria triandra*, Ruiz et Pavon (*Flor. Peruv.*; Steph. and Church, *Med. Bot.*, plate 72; Bentley and Trimen, *Med. Plants*, 30, 31), and of *Krameria tomentosa*, Saint-Hilaire.

Nat. Ord.—Polygalaceæ, Kramerieæ.

Origin.—The *ratanhia* is a low shrub with spreading branches, a native of Bolivia and Peru, and grows in sandy localities in the mountains at an altitude of 3000 to 8000 feet (900–2440 M.); it has a striking appearance from the sessile leaves, which are densely covered with silvery hairs, and from the flowers, which have four scarlet sepals arranged in the form of a cross and four small dissimilar red petals. The root is chiefly exported from Payta, and is therefore distinguished in commerce as *Payta* or *Peruvian rhatany*.

Kr. *tomentosa* was proved by Cotton to be identical with Kr. *grandiflora*, Berg, and Kr. *Ixina*, Linné, var. *granatensis*, Triana. The species Kr. *Ixina*, as recognized by most botanists, extends from North-eastern Brazil northward to Mexico, Venezuela, and the West Indian islands, and exists in several well-marked varieties; it has longer petiolate leaves and loose terminal racemes of red flowers with five dissimilar petals. The root is exported from the Colombian ports of Sabanilla, Cartagena, and Santa Marta, and is known in commerce as *Sabanilla* or *New Granada rhatany*.

Description.—PAYTA RHATANY-ROOT has several knotty heads, and consists of a woody main root, which is 1 or 1½ inches (25–38 Mm.) thick and from 2 to 4 inches (5–10 Cm.) long, when it divides into several spreading and bent branches, 10 to 18 inches (25–45 Cm.) long and varying in thickness from ½ to ½ inch (3–12 Mm.). The latter constitute what is sometimes called *long rhatany*, while the less desirable heads and main root are called *short* or *stumpy rhatany*. The bark is smooth, or in the older roots scaly; of a peculiar rust-brown or blackish-brown color; from ⅓ to ¼ inch (2–3 Mm.) thick; somewhat resinous in the outer, and rather fibrous and brownish-red in the inner, layer. The wood is from six to ten times thicker than the bark, of a pale-brownish or reddish color, and is radially striate by numerous fine medullary rays, very tough, and nearly tasteless. The bark, like the wood, is inodorous, but has a strongly astringent taste, which accounts for the superiority of the *long* root. The tincture made with alcohol gives, with an alcoholic solution of lead, a brownish-red precipitate and a brown-red filtrate (Flückiger).

SAVANILLA RHATANY-ROOT resembles the Peruvian rhatany, but is always less knotty and more slender; its bark has a distinct purplish hue, is smooth or longitudinally somewhat wrinkled, occasionally deep-fissured, and ⅓ to ½ inch (3–4 Mm.) thick; the wood is only three or four times thicker than the bark, the tannin of which appears to differ somewhat from that of the first variety. The alcoholic tincture yields with alcoholic solution of lead acetate a purplish-gray precipitate and a colorless filtrate. Both roots tinge the saliva brown-red; the coloring matter is contained in the bark-parenchyma, in which also small subglobular starch-granules are found; the small bundles of bast-fibres are radially arranged, and accompanied by cells with fine crystals of calcium oxalate.

Payta rhatany alone is recognized by the German Pharmacopœia, while those of the United States, Great Britain, and France admit also the Savanilla variety.

Constituents.—The most important constituent is *ratanhia-tannic acid*, of which Wittstein (1854) obtained nearly 18 per cent. from the bark of Payta rhatany in the form of a red amorphous powder. It is precipitated dark-green by ferric salts and flesh-colored by gelatin, but not precipitated by tartar emetic; on dry distillation *pyrocatechin* distills over. Grabowski (1867) observed that by fusion with potassa the tannin is decomposed

FIG. 170.

Rhatany-Root: a, Payta root; b, Savanilla root.

into *protocatechuic acid* and *phloroglucin*, and that the *ratanhia-red* of Wittstein, which is obtained by boiling with dilute sulphuric acid, has the same composition, $C_{26}H_{22}O_{11}$, as the similar product obtained by Reichleder (1866) from the tannin of the horse-chestnut, and by Rembold (1868) from that of tormentil. The tannins obtained from the three plants appear to have the composition $C_{26}H_{22}O_{11}$. The other constituents of rhatany-root are wax, gum, and uncrystallizable sugar.

Savanilla rhatany contains essentially the same constituents. Wittstein obtained from the bark of *Payta rhatany*, by means of ether, 17.8 per cent., and subsequently, by alcohol, 17 per cent., of extract, while *Savanilla rhatany* yielded respectively 3.2 and 34 per cent. The ethereal extracts contained the tannin described above, but the tannins of the alcoholic extracts appeared to differ in several reactions.

From an extract of rhatany formerly exported from South America, Wittstein isolated a crystalline body which he regarded as identical with *tyrosin*, but which Städeler and Ruge (1862) found to be $C_{10}H_{13}NO_3$; they named it *ratankin*. Gintl (1869) proved it to be identical with the *angelin* of Peckolt, obtained from the *resina d'angelim pedra*, the exudation of Ferreira (Andira, *Saldanha*) *spectabilis*, *Allemao*, and suggested that some kino-like extracts from this and allied plants had been used as substitutes or adulterations of the extract of rhatany.

Other Rhatany Roots have occasionally appeared in commerce.

PARA, BRAZILIAN, OR CEARA RHATANY was described by Berg (1865) and by J. G. S. Cotton (1868) in two varieties as *ratanhia des Antilles*. It has a dark gray-brown or blackish bark, which adheres firmly to the flexible wood, and is longitudinally striate or transversely short-fissured, sometimes dotted with circular warts, and breaks with a glossy somewhat resinous fracture. The relative proportion of bark to wood is about the same as in the *Savanilla* variety, but the bark is not deep-fissured and is destitute of a purple tint. Its alcoholic tincture behaves nearly like that of the former root. Plücker and Hanbury refer it to *Krameria argentea*, *Martius*, which is known in Brazil as *ratanhia da terra*. Several other species of *Krameria* besides the two named are indigenous to Brazil.

KRAMERIA CISTOLDEA, *Hooker*, a native of Chili, produces a root which, according to Schroff (1869), closely resembles *Payta rhatany*; the wood of the thick main root is pale-reddish in the outer layer and brown-red in the centre.

TEXAS RHATANY has been described by Berg; it is derived from *Kr. secundiflora*, *De Candolle*, and consists of a roundish root-stock about 2 inches (5 Cm.) thick, from which a number of long roots emanate which have a blackish-brown, internally reddish, bark of the same thickness as the wood.

Off. Prep.—Extract. *krameriae*, *U. S.*, *Br.*; Extr. *krameriae* fluid., *U. S.*; Infusum *krameriae*, Pulv. catechu comp., *Br.*; Syrup. *krameriae*, *U. S.*; Tinct. *krameriae*, *U. S.*, *Br.*

Medical Action and Uses.—In small doses slightly tonic, in larger doses astringent, in still larger doses rhatany causes dyspeptic uneasiness and oppression, with constipation—effects probably due to its astringent qualities. It has been chiefly employed to restrain *hæmorrhages* of every variety, but is most efficient in those of the passive sort, and particularly in that form of uterine hæmorrhage in which the flow, without being profuse, is habitual. It is not without utility, as an internal medicine, in *uterine leucorrhœa*. It may be used with benefit in atonic and chronic *diarrhœa* and in *incontinence of urine* from debility of the urinary organs.

Locally, it is applied by injection to the treatment of *dysentery*, vaginal *leucorrhœa*, and *gleet*, and has enjoyed considerable reputation as a remedy for *fissure of the anus*. Its mode of action is thought to consist partly in constringing the walls of the rectum, and thereby preventing the formation there of a large fecal mass, which tends to stretch the fissures and render defecation more painful. But it appears also to promote directly the healing of the fissures by limiting the amount of blood that reaches them. The application of it consists merely in emptying the rectum with an emollient enema, and half an hour later throwing into the bowel a solution of 60 or 90 grains (Gm. 4–6) of extract of rhatany in 5 ounces of water. This enema is employed night and morning, and on both occasions it is retained for only a few moments, or else it is allowed to run out at once, and is again thrown into the bowel; and this process is renewed for several minutes at a time. The bowels are meanwhile prevented from becoming confined by the use of appropriate food or of gentle laxatives, such as sulphur, cassia, etc., or, as has been especially recommended, the administration of powdered belladonna-root in the dose of a grain or less (Gm. 0.06), given at night. The administration of the enemata, which is painful at first, gradually and indeed rapidly ceases to be so, and if steadily persevered in a cure is usually effected.

A watery solution of rhatany or its extract is of service in the treatment of *fissured*

nipples. A mixture of the extract with white of egg may also be employed. The part should be cleansed when the child nurses, which ought to be as seldom as possible. In non-syphilitic *ozæna* an infusion of rhatany is sometimes serviceable, introduced into the nostrils with a sponge or injected with a nasal douche several times a day. The addition of chlorinated soda is advantageous, or chloride of lime may be added to the infusion in the proportion of from 5 to 10 grains (Gm. 0.30–0.60) to the ounce of liquid, which, after standing for a time, should be strained.

Administration.—Powdered rhatany is seldom employed, but may be prescribed in doses of from 10 to 30 grains (Gm. 0.50–2.0); the extract, fluid extract, and tincture are officinal.

LABDANUM.—LABDANUM.

Resina ladānum.—*Labdanum*, *Ladanum*, E., Fr., G.

A resinous exudation of *Cistus creticus*, *Liné*, *C. cyprius*, *Lamarek*, *C. ladaniferus*, *Liné*, and of other species of *Cistus*. Bentley and Trimen, *Med. Plants*, 24.

Nat. Ord.—*Cistaceæ*.

Collection.—The resinous exudation of these handsome shrubs, indigenous to Greece and the Levant, is collected during hot weather by means of the *labdanisterion*, consisting of a wooden handle with many narrow leather bands on one end, which are drawn over the branches, the resin being afterward scraped off, and often kneaded together with sand and other material. An inferior kind is obtained from the wool and hairs of sheep and goats which feed on the plants, either by combing or after shearing, by boiling with water.

Description.—Labdanum is met with in two forms—either as blackish or dark-brown masses, which soften and become glutinous in the hands, and are gray upon the fresh fracture, the color soon becoming darker, or as cylindrical rolls about the thickness of a finger and rolled spirally into flat pieces. Sometimes it is also in cylindrical sticks somewhat of the shape of liquorice. Good labdanum is insoluble in water, almost completely soluble in alcohol, fusible, burns when ignited with a bright flame, and has an agreeable balsamic odor and a bitter taste. The roll and stick labdanum are frequently adulterated or artificially made.

Constituents.—According to Guibourt, cake labdanum contains 86 per cent. of resin and volatile oil, 7 of wax, 1 of extractive matter, and 6 per cent. of insoluble impurities. Pelletier found in roll labdanum only 20 per cent. of resin and 72 per cent. of sand.

Medical Action and Uses.—The singularly grateful odor of this resin led to its being made use of in the most ancient times for the fumigation of rooms and clothing, and as a medicine both internally and externally for the same purposes as other aromatic resins. It was used internally and by fumigation for chronic *bronchitis*, and locally in *leucorrhæa* and other uterine affections; it was also prized as a *diuretic*. Later it became an ingredient of various stimulant plasters. Its use is now obsolete.

LABURNUM.—LABURNUM.

Golden chain, *Bean trefoil*, E.; *Faux ébénier*, *Cytise*, Fr.; *Goldregen*, *Bohnenbaum*, G.

Cytisus Laburnum, *Liné*.

Nat. Ord.—*Leguminosæ*, *Papilionaceæ*.

Description.—This is a tall shrub or low tree indigenous to Southern Europe, and planted in this country for ornament. It grows to the height of 15 or 20 feet (4.5–6 M.), and has a smooth bark. The leaves are on slender petioles, trifoliate, with nearly sessile, oval-oblong, obtuse, and mucronate leaflets, which are about 2 inches (5 Cm.) long, smooth and dark-green above, soft hairy and grayish beneath; they have a somewhat saline, bitterish, and slightly acrid taste. The golden-yellow flowers are in long hanging racemes, and produce linear, obtuse legumes containing glossy, dark-brown, nearly reniform seeds of a disagreeable bitter and acrid taste.

Constituents.—Chevallier and Lassaigne obtained the bitter principle of the ripe seed in an amorphous condition and named it *cytisin*. T. Scott Gray (1862) obtained, in addition thereto, *laburnic acid* and two neutral bitter principles, *cystin* (*cytistin*?) and *laburnin*, which are present chiefly in the seed and bark. These principles appear to be the more or less impure alkaloid *citysine* of Husemann and Marmé (1865). This is white, crystallizable, inodorous, of a bitterish and somewhat caustic taste and strong alkaline

reaction, easily soluble in water and alcohol, but nearly insoluble in ether, chloroform, benzol, and carbon bisulphide; it melts at 154.5° C. (310° F.), and is sublimable in thin needles or scales. Warm nitric acid colors it orange-yellow; sulphuric acid and potassium dichromate, yellow, brown, and green. The salts are mostly deliquescent, and crystallize with difficulty. Its composition is $C_{20}H_{27}N_3O$. The leaves contain only traces of it; it is likewise found in the seeds of other species of *Cytisus*.

Physiological Action.—*On Animals:* According to Dr. Gray (*Edinb. Med. Jour.*, vii. 908, 1025), its effects upon dogs, cats, and rabbits are nearly identical. The decoction, however administered, is apt to cause vomiting, and also languor and muscular relaxation, the breathing and pulse-rate are accelerated, and there is always a greater or less tendency to sleep, which, however, is never comatose or profound. No irritant effects due to laburnum or any of its constituents are found after death. Fatal doses induce vomiting, and then more or less of the symptoms before enumerated, but with spasm rather than resolution; death follows gradually, the heart continuing to pulsate until the end. After death the brain and spinal cord are engorged, as are also the veins of the right side of the heart, but the lungs are collapsed and the left side of the heart is empty. Cytisin, laburnin, and laburnic acid, considered as separate active elements of laburnum, appear to act in very nearly the same manner.

On Man: In medicinal doses it induces a slight degree of languor and tendency to sleep, rather confines than relaxes the bowels, and very slightly, if at all, increases the urinary secretion. Larger doses are very apt to produce a somewhat soporific effect, and are sure to excite vomiting and sometimes purging, as well as some quickness of the pulse and giddiness. The same effects are induced by cytisin, and each of the other alleged proximate principles appears to cause some drowsiness and contraction of the pupils. In cases of poisoning by the bark or berries, which have been very numerous in Europe, the effects observed are remarkably uniform. They comprise the following phenomena: Vomiting, pain in the stomach, which is sometimes excruciating; purging; dryness, heat, and constriction of the throat; faintness, languor, vertigo, drowsiness, or a narcotic sleep, with slow and stertorous breathing, followed by insomnia; the eyes are dull and sunken, the pupils dilated, and the eyelids dusky; the pulse is very weak or fluttering, varying between 90 and 100; thirst is usually marked, and in the worst cases muscular twitchings of the neck and face are observed. No headache or other pain, except that in the stomach, is complained of, nor do general convulsions occur. In one or two instances the urine has been temporarily grass-green (*Med. Record*, xii. 696). In no case has death been observed.

Medical Uses.—Laburnum was recommended by Dr. Gray in *bilious dyspepsia*, with periodical attacks of bilious vomiting, diarrhoea, and constipation in the intervals, to be taken in such small doses as not to sicken the patient, thrice daily before meals and continued for 6 or 8 weeks. He also regarded it as an efficient medicine for children who vomit after eating, as a palliative of *whooping cough*, of the *nausea* and sickness of pregnancy, of *asthma* connected with emphysema of the lungs, etc. These recommendations have not, as yet, been confirmed by experience. Their author proposes for use a decoction of laburnum concentrated until it attains a specific gravity of 1.034, to be given in doses of from 2 to 40 minims. The dose of the extract is stated to be from $\frac{1}{10}$ grain to 1 grain (Gm. 0.006–0.06); of cytisin, from $\frac{1}{2}$ grain to 4 grains (Gm. 0.03–0.26); of laburnic acid, from 1 to 6 grains (Gm. 0.06–0.40); and of laburnin, from 5 to 12 grains (Gm. 0.30–0.80).

In cases of *poisoning* the stomach should be evacuated by warm water and ammonia and alcohol administered internally.

LAC, Br.—MLK.

Lac vaccinum.—Lait, Fr.; Milch, G.

The fresh milk of the cow, *Bos Taurus*, *Linné*.

Class Mammalia; Order Ruminantia.

Description.—Cow's milk is an opaque white liquid having a faint alkaline or neutral reaction, a slight peculiar odor, and a bland and sweet taste; its specific gravity is about 1.030. Viewed under the microscope, it is seen to be a clear and transparent liquid in which a large number of minute globules are suspended. On standing, these rise to the surface as a yellowish stratum, the *cream*, which constitutes about 5.0 per cent. of the milk, and consists mainly of fat mixed with some casein and retaining some serum. By churning the globules unite to form *butter*, and the liquid which separates, and is

known as *buttermilk*, is essentially a solution of *milk-sugar* and the saline constituents of milk, and contains some casein and butter. The milk from which the cream has been separated is called *skim milk*. If left to itself, it becomes acid and separates the casein in a coagulated condition called *curds*; the same effect is produced by rennet and by acids. The liquid separated from the coagulum is called *whey*, and contains chiefly milk-sugar and some salts. The blue color sometimes observed in milk, according to Reiset (1883), is due to a blue fungus.

Milk possesses great emulsifying capacity, forming permanent emulsions on agitation with ether, chloroform, alcohol, benzin, carbon disulphide, etc., as was shown by Gust. Pile (1883); a mixture of equal volumes of milk and chloroform separates but slightly after several hours. Milk produces a blue color with tincture of guaiacum, unless it had been heated to about 80° C. (176° F.) or a mineral acid or caustic alkali had been added.

Constituents.—The chemical constituents of the milk of mammals are qualitatively alike, but quantitatively vary very much for different species, for different individuals, and even for the same individual, depending in the latter case upon the length of time since the last birth, upon the kind and quantity of food, and upon the exertion or rest of the individual. The following table is compiled from the averages given by Lehmann and others (*Physiol. Chemistry*):

	MILK OF					
	Woman.	Cow.	Mare.	Goat.	Sheep.	Sow.
Albuminoids (protein compounds).....	2.5	4.1	1.7	5.0	4.5	6.2
Fat (butter).....	3.6	4.0	0.8	3.7	4.2	5.8
Milk-sugar.....	6.5	4.2	8.8	4.5	5.0	5.3
Salts (chiefly phosphates).....	0.5	0.7	0.4	0.6	0.7	0.9
Total solids.....	13.1	13.0	11.7	13.8	14.4	18.2
Water.....	86.9	87.0	88.3	86.2	85.6	81.8

The albuminoids consist of *casein* and *lactoprotein*. Casein is not coagulated by heat, but on evaporating its aqueous solution it becomes insoluble and separates in the form of a thin skin; acetic and other acids coagulate it; so does rennet, and after this ceases to have any further effect, acetic acid will produce another coagulation. The protein compounds of the different milks, however, vary slightly in their behavior to some reagents. Schmidt-Muehlheim (1883) showed that fresh milk contains between .08 and .19 per cent. of *peptone*, and that this quantity is increased at the expense of the casein by digestion at 40° C. (104° F.). To obtain the peptone the protein is precipitated with table-salt and acetic acid, and afterward the peptone by phosphotungstic acid; this precipitate, dissolved in caustic soda, shows the reactions of peptone. (See OVUM.)

Butter, as obtained by the churning of cream, is a very complex mixture of fats with small quantities of an odorous principle, casein, milk-sugar, salts, and water; the fats are glycerides of butyric, capronic, caprinic, myristic, palmitic, stearic, and oleic acids, some of which are gradually decomposed, whereby the liquid fatty acids are liberated and the butter turns *rancid*.

As stated above, milk left to itself becomes acid; the change takes place in consequence of the fermentation of milk-sugar (see SACCHARUM LACTIS) induced by the casein, whereby *lactic acid* is generated. The change is prevented, for some time at least, by the addition of certain compounds, for which purpose borax has been recommended; but boric acid, in the proportion of 1 to 1000 milk, as recommended by Hirschberg (1871), is preferable, as not altering the taste. Salicylic acid (1 to about 5000 milk) has also been found serviceable. If kept in vessels closed by Appert's method, it separates into several strata, but remains unchanged, provided it had been heated for some time to 120° C. (248° F.). Naegeli, and afterward C. Loew (1882), showed that milk preserved at a lower heat gradually becomes intensely bitter and brown, the albuminoids being peptonized and partly converted into leucin, tyrosin, and ammonia, and the milk-sugar into lactose and glucose. More recently, *concentrated* or *condensed milk* has been introduced, which is simply fresh milk mixed with a certain proportion of sugar and evaporated at a low temperature to the consistence of a thick syrup or soft extract, in which condition it will keep well.

Adulteration.—When milk is mixed with water its specific gravity is lowered; skim-milk, on the other hand, has a higher density. To detect adulterations, the quantity of the solids is determined by evaporation to dryness; from this the amount of fat is ascertained by treating with ether or petroleum benzin, and the residue is either incinerated to determine the amount of mineral constituents and estimate the albuminoids

and sugar combined by the loss in weight, or the residue insoluble in ether is treated with alcohol and water, which leave casein and dissolve the sugar and salts. Since the milk residue is dried and afterward exhausted with difficulty, some chemists prefer to evaporate the milk mixed with a known quantity of dry sand, calcium sulphate, or similar material.

Various instruments, called *lactometers*, have been constructed with the view of ascertaining rapidly the purity of milk by determining either the density, the degree of opacity, the percentage of cream, or the amount of butter.

Pharmaceutical Uses.—Milk is used in preparing *Mistura scammonii*, *Br.*; and in the preparation of wheys, which are official in several European pharmacopœias.

SERUM LACTIS, SERUM LACTIS DULCE.—Whey, *E.*; Petit-lait, *Fr.*; Molken, *G.*—Take of fresh cows' milk 200 parts, rennet wine 1 part; mix and warm to 35° or 40° C. (95° or 104° F.), and after coagulation strain from the curd.

SERUM LACTIS ACIDUM. s. *Serum lactis, F. Cod.*—Acid whey, *E.*; Petit-lait acide, *Fr.*; Saure Molken, *G.*—Heat fresh cows' milk 100 parts to boiling, add 1 part of potassium bitartrate (or 0.1 part of citric acid dissolved in 1 part of water), and when completely coagulated strain.

SERUM LACTIS ALUMINATUM.—Alum whey, *E.*; Petit-lait alumineux, *Fr.*; Alaunmolken, *G.*—It is prepared like the preceding, except that 1 part of powdered alum is used to effect the coagulation.

SERUM LACTIS TAMARINDINATUM.—Tamarind whey, *E.*; Petit-lait tamariné, *Fr.*; Tamarinden-Molken, *G.*—The coagulation of 100 parts of milk is effected with 4 parts of tamarinds, and the strained whey has a brownish color.

KOUMYS or **KUMISS** is fermented mares' milk, which is extensively employed as a beverage and for medicinal purposes by the Kirgheez, Kalmucks, Turkomans, Nogays, and other nomad tribes of the Russian Empire. The process for preparing it differs somewhat with the different tribes, but in all cases consists in inducing fermentation by the addition of yeast to fresh mares' milk, and in stirring this occasionally; the product obtained in about 12 hours is known as *ssaumal* or *staumgal*; on being kept for several days it becomes much stronger, of a more decided acid taste, and very sparkling from the confined carbonic acid gas. For the preparation of koumys from cows' milk the following directions are given by Wilckens (1874): A clean champagne-bottle is filled with the fresh milk, 20 or 30 Gm. of sugar are added, and compressed yeast about the size of two peas; the bottle is well corked, the cork tied securely, and the milk kept in a warm room for 2 days, and frequently shaken during that time; afterward the bottle is placed in an upright position in the cellar, and after 3 more days the koumys is fit for use. The proportions used by Dr. L. Wolff (1880) are: Grape-sugar $\frac{1}{2}$ ounce, water 4 ounces, compressed yeast 20 grains, cows' milk sufficient for a quart champagne-bottle: ferment for 3 or 4 days at 10° C. (50° F.) or less; this koumys will keep 4 or 5 days. According to Jagielski (1874), the fermentation, once started, will continue in corked bottles and at a low temperature, resulting in an increase of alcohol, carbonic acid, and lactic acid: cows' milk is preferable for the preparation of koumys, this being free from disagreeable odor and taste. For special purposes the milk is somewhat diluted before fermentation or the whey only used in making koumys.

KEPHIR or **KEFIR** is likewise fermented milk, but fermentation is produced by a substance of unknown origin, called kephir-ferment or kephir-seed. This liquid has been long in use by the Caucasian mountaineers. Through an investigation made with the ferment by E. Kern (1881) it became known in Europe, and is now to some extent used medicinally.

Medical History.—In the Hebrew Scriptures milk is constantly referred to for its precious qualities as food, and no more striking figure could be employed to represent the exuberant riches of a country than that it was a "land flowing with milk and honey;" that is to say, suitable for raising herds and grain. Milk is the most essential article of food for man before his teeth are matured for mastication, as well as in that second childhood when "the grinders cease because they are few," especially when it is associated with wine, which is "the milk of old age." Not less does it become the essential and most salutary food of man when at any period of his life he is enfeebled by disease. The qualities that adapt it to these several states or conditions of life are—the facility of eating it, for it requires no mastication; the rapidity of digesting it, since it needs but little change to convert it into assimilable material; and the small amount of waste which it involves and of digestive power which it requires, since the fecal residue of its digestion is less than from any other food.

The ancients used milk from the cow, the camel, the mare, the ass, the goat, and the sheep, and attributed to several of these products special virtues or defects; thus, sheep's milk was considered binding, ass's and goat's milk rather relaxing, and to cow's milk intermediate qualities were ascribed. A full summary of the subject is furnished by Pliny, who represents human milk as the most nutritious, and goat's milk next in strength, and calls to memory the myth that Jupiter was suckled by a goat. The mildest milk, according to Pliny, is the camel's. He very correctly remarks that crude milk is more flatulent and less wholesome than boiled milk. He states that milk is used for all manner of internal inflammations, including those of the kidneys, bladder, bowels, throat, and lungs, and externally for itching and watery eruptions of the skin, and refers to its employment, as Celsus also did, in the cure of phthisis. He speaks of its value in other cachexiæ, and especially of the cure of chronic gout by ass's milk, and also of milk in general in the treatment of dysentery and of poisoning by colchicum, conium, etc. He refers particularly to ass's milk in marasmus and other wasting diseases, and to the use in affections of the spleen of milk from goats that had fed on ivy. He describes the mode of preparing whey, and its uses in epilepsy, melancholy, paralysis, and diseases of the skin. Milk was also applied topically in ophthalmia and in ulcerations of the mouth, throat, and uterus. According to Galen, cows were fed with certain medicinal plants in order to render their milk curative of particular diseases. Arabian physicians used a milk diet in consumption. About the beginning of the eighteenth century the milk treatment enjoyed a great vogue under the influence of F. Hoffmann. Since 1865, when Karell prescribed the systematic use of skim-milk as the sole remedy for various chronic diseases, his method has been adopted by prominent physicians in several countries. The secretion with the milk of various drugs and medicines is a subject of much importance, but cannot occupy us here. (See Stumpf, *Deutsches Archiv für klinische Medicin*, Jan. 18, 1882; Dolan, *Practitioner*, xxvi. 85, 165, 251, 331, 477.)

Medical Action and Uses.—The special action of milk, considered as a therapeutical agent, is that, while it affords sufficient nutriment, it moderates the stimulating action of the blood and restricts the excrementitious waste derived from the food, thereby enabling the organs which are obstructed by blood, by secretions, or by more or less plastic exudations to purge themselves of these hindrances to a free and normal action. In a word, it gives rest, which is the primary condition of cure, and removes hindrances to a return of that functional activity which is an essential condition of health. The milk treatment is essentially a "hunger treatment," and is analogous to that natural and instinctive abstinence from food which is observed in all acute febrile diseases and in the greater number of chronic disorders, and which is the cry of Nature to be let alone—to be spared that officious assiduity which is as mischievous in dietetics as in medicinal therapeutics. This we conceive to be the simple explanation of the curative powers of milk. Dr. S. Weir Mitchell has stated that during the treatment by skim-milk patients always lose weight at first, and that so long as its use is continued uric acid completely disappears from the urine, which becomes pale and whey-like, while the feces grow pale, hard, and odorless. Tortured as it may be by physiological experiment, milk reveals no special action upon this or that organ or anatomical element, but so modifies the whole system as to restore its soundness without the aid of drugs, or else enables them to produce results which without its aid they would have been unable to accomplish. It is perhaps not always remembered that milk and alcohol in the form of "milk punch" contain at once the most perfect nutrient and the most efficient condiment that could possibly be used under the circumstances in which this preparation is usually employed.

Of all forms of food that can be used in *fevers* and *inflammations*, there is no doubt that milk is the best whenever the decline of the fever and the process of wasting have begun. Before this period watery preparations of starchy products, especially of barley and rice, are sufficient, but as soon as tissue-waste shows itself a portion of milk should be added to them, and gradually increased until it forms the principal part of the nourishment or is supplemented by the stimulant operation of beef-tea. In less acute affections, and especially in those attended with suppuration or an excessive discharge of blood, serum, or mucus, nothing so well as milk maintains the strength without tending to excite fever. When inflammatory or ulcerative lesions exist in the stomach or bowels the use of milk can hardly be dispensed with. In *simple gastric ulcer* it is the one remedy which may be depended upon for a permanent cure; and in *cancer* of the stomach or bowels it is infinitely the best palliative, and the only one, by means of which life may with any certainty be prolonged. But in these and similar cases the quantity of the milk employed must be carefully adjusted to the tolerance of the digestive organs, and,

if necessary, its retention favored and its assimilation promoted by the addition of lime-water or by preceding the administration of each portion with a dose of bismuth. The same remarks apply to *dysentery*, both in its acute and chronic forms, provided that in the acute disease whey or milk-and-water or buttermilk is employed rather than pure milk. The last is most efficient in the chronic form, if it be administered with a due regard to its tolerance by the patient. In almost all of the gastric disorders in which vomiting depends upon irritability of the stomach lime-water and milk in equal proportions, and in small doses at a time, form one of the most efficient remedies. M. Debove has proposed that in order to introduce into the stomach the largest necessary quantity of milk there should be added to the skim-milk to be given a proportion of desiccated milk in pulverulent form, so that the percentage of nutritive matter in the mixture shall be much greater than in milk alone. In not a few cases *albuminuria* due to desquamative nephritis has been cured by the persistent use of an exclusive milk diet, and in others by an association with it of ferruginous-saline mineral waters or of official preparations of iron. Even in those less curable cases of interstitial nephritis associated with hepatic and cardiac lesions there can be no doubt that this method tends to remove the dropsy, and at the same time to quiet the morbid violence of the heart's action, while it greatly improves the nutrition of the system. Some years ago several physicians announced the cure of *diabetes* by a milk diet, but longer observation showed that they must have been deceived and that its treatment by milk aggravates the disease. In regard to a milk diet in *chronic diseases of the lungs*, whether tuberculous or bronchitic, with their associated affections pleurisy and emphysema, it suffices to say that, as a rule, it is contraindicated, as affording too little nutriment when there is need of all that can be assimilated. In point of fact, a milk diet, as such, never cured, or even ameliorated, any one of them; but its use has been followed by favorable results, even in consumption, when it has been associated with other favorable hygienic influences, such as a pure, dry atmosphere, active and regular exercise, a complete change in the habits of living, abstention from the use of perturbative drugs, and a nutritious diet fitted to compensate for the defects of the milk regimen in this respect. In almost every cachectic condition milk is the most reliable article of food. Different kinds of milk, and especially ass's and goat's milk, have been reputed to be remedies for consumption and *scrofula*; and beyond a doubt a milk diet, with an appropriate regimen in other respects, is a very efficient means of invigorating the strumous constitution. Lime-water, which has always had a similar reputation, should be associated with the milk. A milk-and-vegetable diet has long been used in the treatment of *epilepsy*, and its operation is intelligible by analogy when we consider that every remedy that has been most useful in this disease, from the time of Aretæus, who declared, "from flesh in particular the patient is to be entirely restricted," down to the introduction of the bromides, has been a sedative of the nervous and circulatory systems. Milk is one of the most convenient and efficient antidotes for nearly all corrosive poisons, acids, alkalies, and metallic salts, because with some of them it forms compounds that are not readily soluble, and all of them it envelops in its curd, and thus tends to prevent inflammation or absorption until proper emetics can be administered.

The close analogies of milk and chyle led to the use of the former by its injection into the veins, which was tried by Donné in 1842, and without causing any alarming symptoms. Later it was employed fruitlessly by Bovell and by Herepath in *cholera*, and about 1860 by Hodder of Toronto in a case of complete collapse, in which reaction and recovery followed. Subsequently, Dr. Howe, and then Dr. Thomas of New York, made use of the same method, the one in *phthisis*, the other in *traumatic hæmorrhage*, and in no case did any alarming symptoms arise when the milk employed was perfectly fresh. The latter physician pronounced it a safe and legitimate remedy, expressing his conviction that the intravenous injection of milk will answer nearly as good a purpose as that of blood, and predicting for it a brilliant and useful future. Subsequently, however, Dr. Howe performed a number of experiments upon dogs, depleting the animals, and then injecting into the veins or the arteries a less amount of milk than that of the blood abstracted. Thus he removed by depletion from 8 to 16 ounces of blood, and replaced it with from 6 to 10 ounces of milk. All of the animals died, but two dogs bled in the same manner, and not injected, recovered. Certain experiments of Brown-Séquard proved that much smaller quantities of milk, such as 95 Gm. (3½j), might, under similar circumstances, be tolerated. Afterward, Wolfsberg found that animals would bear the injection of milk to the extent of three-fourths of 1 per cent. of the quantity of blood abstracted, but that more than this speedily destroyed them. He also was unable to preserve the life of dogs by this treatment; their weight declined, and they died of inanition without obvious dis-

ease. Meanwhile, attempts were made to preserve or prolong life by this treatment in patients affected with various diseases by Hunter and Pepper in America and Macdonnell and Meldon in Europe, with results which do not sustain the favorable anticipations referred to above, and which led Dr. Thomas to state that intravenous injection of milk should be used not only in hæmorrhage, but also in Asiatic cholera, pernicious anæmia, typhoid fever, and puerperal convulsions. Dr. Howe, who was the first in this country to employ it, declares not only that his own experience gives him little faith in its utility, but that "it is a dangerous operation, and one that should only be resorted to when blood cannot be obtained." In several cases the patient was attacked with vertigo, dimness of vision, twitching of the eyeballs, and dyspnoea. In other cases it conferred no sensible or lasting advantage, but only postponed the fatal result. Dr. Pepper, who employed it in a case of progressive organic anæmia, effected no material relief, and is of opinion that in cases of intense anæmia connected with serious but curable disease, although doubtless of much service, the severe symptoms following the operation and the possible dangers attending it render it improper to perform it until all other remedies have failed. It is difficult to conceive on what rational grounds such an operation should ever have been undertaken. Its proposers would seem to have considered that the elaborate mechanism provided by nature for the digestion of milk in infancy is useless or superfluous—that the casein which requires the action of the gastric juice, and the butter which needs the bile and pancreatic secretions, to fit them for absorption and nutrition, need not be subjected to any such preparation, but might at once be mixed with the blood and converted directly into tissue! That the water and salts, and possibly even the sugar, may, when so introduced, be capable of sustaining life for a short time, is rendered probable by the results of saline injections into the veins in epidemic cholera; but in regard to milk as a whole experience has confirmed the plainest deductions from physiological law, and proved the operation to be dangerous as well as irrational. These conclusions have been confirmed by the more recent experiments of Moutard-Martin and Richet, and of Demetre Culeer (*Bull. de thérap.*, xevii. 136; xeviii. 89), who found that death was caused by caseous emboli in the medulla oblongata; and by Béchamp and Baltus, who conclude that the operation cannot form a substitute for the transfusion of blood (*Archives gén.*, Août, 1879, p. 228). It should perhaps be added that Dr. Meldon of Dublin claims to have rescued a phthisical patient from death for at least 6 months by a single intravenous injection of 3½ ounces of milk. He performed the operation, only as a last resort, in ten cases, four of which were cured, and were all of them cases of "pernicious anæmia" (*Med. News and Abstract*, xxxviii. 265). Such a result was unparalleled when it was announced in 1880, and has not been matched since then.

Milk may be used topically as an emollient and demulcent. It is a popular remedy for *ophthalmia* in infants, and especially in nursing infants, to instil the mother's milk in the eyes, and human and warm cow's milk are applied to various local cutaneous inflammations, such as *erythema*, *intertrigo*, *otorrhœa*, etc. A poultice made by stirring bread-crumbs in hot milk is in common use to promote suppuration in *abscesses*. If its application is long continued, it is apt to render the skin sodden and wrinkled. It should be prevented from adhering by the addition of a little lard or glycerin.

Administration.—According to Karell, a chief apostle of the "milk cure," it is essential that the patient abstain from all other food but milk, and that he should take it at fixed hours and in determinate quantities. The milk, we are told, must be skimmed, but that degree of exaction is not required by others who employ the method. It should be warmed, not hot, in winter, cool, but not iced, in summer, and should be swallowed by small mouthfuls and slowly. If the stools are consistent, the quantity of milk may be gradually increased until from 4 to 6 pints a day are taken. Almost always a primary effect of the treatment is to produce constipation, which must be overcome by a little castor oil or rhubarb or by a roasted apple or stewed prunes. Sometimes much more energetic modes of treatment are called for. If, on the other hand, the milk food undergoes decomposition, producing flatulence or diarrhœa, a certain proportion of lime-water should be mixed with it, or the milk should not be taken unless it has been boiled. When its use is attended with a coated tongue and dyspeptic symptoms the cause is generally a febrile condition, originating in the imperfectly-digested milk contained in the alimentary canal. If the patient is thirsty, he may drink pure water or carbonated water. Toward the third week of this process, if he grows weary of it, he may be allowed a little stale bread once a day, or grits or other analogous preparations may be added to the milk. To carry out this discipline requires the patient to be endowed with a degree of courage approaching heroism; but in certain cases it brings a due reward: the flesh and strength,

which had before been declining under the combined influence of pain, indigestion, and scanty nourishment, begin to improve, and thus persons of resolution are encouraged to endure their martyrdom.

It may be stated here that *condensed milk* is in many cases a valuable substitute for fresh milk in all cases of sickness calling for the use of milk, and especially when good milk cannot be procured from the cow. This is notoriously the case at most of our seaside resorts, and it occurs also where the drinking-water is unduly mineralized.

SERUM LACTIS, Whey. This preparation, which contains little else than sugar of milk and a fractional percentage of salts, and is nutritious chiefly through its watery element, has been used from time immemorial as a drink in fevers. It is agreeable to the taste, or may be rendered so by lemon-juice or by tamarinds, as was the custom in Sydenham's day, and is also more or less diuretic and laxative. Taken copiously and hot, it was at that time the favorite diaphoretic at the commencement of febrile attacks due to cold. When whey is drunk to the extent of a pint or two every day, and for several weeks together, it tends to derange the stomach, impair the appetite, and produce diarrhoea, and is therefore improper in all chronic diseases in which the digestive organs are already enfeebled. On the other hand, it may, as far as it goes, prove useful in chronic blood disorders like *gout*, *rheumatism*, and *gravel*, with congestion of the brain or of the portal circulation, owing to its depurative and somewhat diuretic qualities, which it owes to the salts which it contains. But in Germany, where alone the "whey cure" is systematically employed, it is pursued in localities in which pure air and exercise and the various food, to say nothing of the mineral waters usually taken at the same time, doubtless have much more to do with the cure of disease than the systematic drinking of whey. *Wine-whey* is made by adding to a pint of milk, at a boiling heat, from 2 to 8 ounces of sherry wine, straining off the whey, and sweetening it. It is a mildly stimulant and nutritive drink, much used in the *typhoid state* of febrile diseases.

BUTTERMILK, or the thin sour milk separated from the cream by churning, contains casein, but very little butter. Even by many persons in health it is considered a most refreshing drink, and there is no form of *fever* in which it is not apt to be relished, probably on account of its acidulous taste. It is one of the very best remedies that can be employed in acute and even in chronic *dysentery*, promptly allaying the tenesmus and modifying the bloody and mucous stools of the acute form, and lessening the frequency of the evacuations in the chronic disease. Its effects in *typhoid fever* are scarcely less striking. It renders the discharges less numerous and moderates the tympanites. It should be given in doses of from 2 to 4 ounces every three or four hours, and always as fresh as possible.

KOUMYS is a drink imitated from the Tartars, and which may be considered a peculiar form of milk punch, since it contains the saline and protein constituents along with the sugar, fat, and lactic acid of the milk, together with carbonic acid and alcohol, the latter constituents varying with the time employed in the fermentation. It is therefore a nourishing and stimulating drink, sometimes even an intoxicating one, since the longer it is kept the more alcohol it contains. One analysis states that at the end of 16 days it yields upward of 20 parts of alcohol in 1000. The effects of drinking 2 or 3 glasses of koumys are identical with those of alcohol—a general diffusive glow, a quickening of the pulse, a pleasurable excitement of mind and body. Like alcohol, indulged in overmuch it impairs the appetite for food, tends to constipate the bowels, renders one dull and sleepy, and augments the urinary solids. Moderately used, it promotes digestion and nutrition, or at least increases the weight by augmenting the fat, precisely like milk punch. Like that familiar drink, it is of more or less use in various wasting diseases, including *consumption* and *nervous exhaustion*, chronic *dyspeptic* disorders, chronic *diarrhoea*, *anæmia*, *chlorosis*, *malarial cachexia*, etc. In the 2d edition of the Dispensatory we made use of the following words: "It is not to be wondered at that in Germany a counterfeit koumys is prepared with milk, lemon, and rum. There is good reason to fear that the general fondness for sparkling wines and other effervescing drinks may tend to render fashionable a draught which, under the disguise of a medicine, partakes more or less of their intoxicating qualities, and may become the prime cause of a baleful habit of intoxication. There is much danger also lest its votaries overlook the essential conditions of its utility—active exercise in the open air and those other hygienic measures upon which the utility of alcohol and other hydrocarbons in all chronic wasting diseases essentially depends." More recently, as we learn from Stange (*Von Zrimssen's Handbuch der allgemeinen Therapie*, 1883, i. 403), "favorable results from the koumys treatment can be expected only in the steppes of Russia, where not only is the preparation properly made,

but a dry, hot climate exists, which is essential to the success of the method. The proper koumys can only be prepared from the milk of a special race of mares fed on the peculiar grasses of the steppes alone and subjected to no labor." And Dr. Carrick of St. Petersburg stated to the Medico-Chirurgical Society of Edinburgh that "the best effect of the koumys cure was to be got not only by taking the remedy itself, but by going to the Russian steppes to partake of it there" (*Edinb. Med. Jour.*, xxvii. 167).

LACCA.—LAC.

Resina (Gummi) lacca.—*Laque, Gomme lacque, Fr.; Lack, Gummilack, G.*

A resinous exudation produced by the puncture of *Coccus Lacca, Kerr.*

Origin.—The hemipterous insects thus named congregate in large numbers upon the tender branchlets of various East Indian (mostly laticiferous) trees, and become surrounded with the resinous exudation, which gradually hardens. The impregnated, much-enlarged female insects, imbedded in the resin, contain a red coloring matter, in which the young larvæ are developed. These finally eat a passage through the incrustating material and escape. The branches are collected with the incrustation, which is considered more valuable if still containing the red coloring matter. Among the trees yielding lac are the following: *Aleurites laccifera, Willdenow* (*Croton, Linné*) (Nat. Ord. Euphorbiaceæ); *Ficus indica, Roxburgh, F. bengalensis, Linné, F. religiosa, Linné, F. Tsjela, Hamilton* (Nat. Ord. Urticaceæ); *Schleichera trijuga, Willdenow* (Nat. Ord. Sapindaceæ); *Butea frondosa, Roxburgh, s. Erythrina monosperma, Lamarché* (Nat. Ord. Leguminosæ). According to Stillman (1880), lac may also be collected from *Acacia Greggii, Gray*, and from the *creasote-bush* or *stinkweed, Larrea mexicana, Moricand, s. L. glutinosa, Engelmann*, which plants grow from Western Texas to Mexico and Southern California.

Description.—The thin branches, almost completely covered with numerous small resin-nodules, constitute the *stick-lac*. The separate nodules or tears are red-brown, and contain in the interior a dark blackish-red powder; after the escape of the young insects the resin is brown. The same resin, after having been detached from the twigs, constitutes the *seed-lac* or *grain-lac*. It is in irregular fragments of the size of a pea and smaller, yellowish-brown or reddish, somewhat shiny, and nearly tasteless. After boiling the stick-lac or seed-lac with water, fusing the resin, and congealing it upon a smooth surface, *shellac* is obtained; it comes in thin, glossy, and more or less transparent fragments. Sometimes *grape-lac* and *lump-lac* have been distinguished, the former of which consists of agglutinated incrustations separated from the twigs; the latter is identical with shellac, except that it has not been congealed in thin layers. When chewed, stick-lac softens and colors the saliva purplish-red, a slight bitterish and astringent taste being perceived; when burned, it gives off a strong and agreeable odor. The water in which red stick-lac has been boiled on being treated with alum yields *lac-dye*.

Shellac is soluble in potassa, soda, borax, and hydrochloric and acetic acids, and when digested with ammonia in close vessels swells to a gelatinous mass. By treating the alkaline solution with chlorine or sulphurous acid bleached shellac is obtained.

In the year 1876–77 the importation of stick- and seed-lac amounted to 47,000 pounds, and of lac-dye to 454,781 pounds. In 1882 nearly 3,250,000 pounds of shellac and about 40,000 pounds of lac-dye were imported.

Constituents.—Lac is a complex body, containing, according to Unverdorben, five distinct resins, besides wax, fat, and coloring and extractive matter. The resins which may be separated by their different behavior to alcohol, ether, and alkalies are present in seed-lac, according to Hatchett and John, to the amount of 66 or 68 per cent., but shellac contains fully 90 per cent. of resin. The wax has been found to vary in amount between about 2 and 6 per cent.

Uses.—Shellac is used in the preparation of *varnish* and of *sealing-wax*, the latter by fusing from 5 to 8 parts of it with 1 part of turpentine and coloring the mixture with a suitable pigment. *Varnish* suitable for blackboards is made by digesting and intimately mixing shellac, mastic, sandarac, white turpentine, emery-flour, and lampblack, of each 1 ounce, and alcohol 2 pints. A solution, made without heat, of 1 part of powdered bleached shellac in 2 or 3 parts of a saturated solution of borax is recommended by Geissler (1880) as an excellent *starch-gloss*, also as a *varnish* for maps and prints. An *ink* useful for laboratory purposes is obtained by mixing lampblack with a solution of 100 grains of shellac and 20 grains of borax in 4 ounces of water.

Medical Action and Uses.—Having in a slight degree some of the qualities of

the resins, lac has been used in combination with astringents as an application to indolent ulcers, especially of a scrofulous and scorbutic sort. It is rarely employed in medicine.

LACMUS.—LITMUS.

Lacca cœrulea, *Lacca musica*.—*Tournesol*, *Laque bleu*, Fr.; *Lackmus*, G.

A blue pigment obtained from *Lecanora tartarea*, *Acharius*, *Roccella tinctoria*, *Ach.*, *R. fusiformis*, *Ach.*, and from other lichens.

Preparation.—The lichens are powdered, mixed with some potash and urine or other ammoniacal liquid, and exposed to the air. The liquid acquires a red, purple, and finally blue color, and is mixed with sufficient chalk to be formed into small rectangular cakes. It is manufactured in Holland.

Description.—Litmus is in earthy, friable cakes of a deep-blue or purplish-blue color and a slight saline and somewhat pungent taste. It effervesces with acids, and is partly soluble in water with a blue, and in dilute alcohol with a purplish-blue, color, which is changed to red by acids.

Constituents.—Besides the earthy matter, Kane (1841) separated from litmus four coloring matters—namely, *erythrolein*, a purplish-red fatty matter, soluble in ether, fusible at 38° C. (100° F.), and yielding with ammonia a purple-colored solution; *erythrolitmin*, red, crystalline, insoluble in ether, soluble in alcohol, and changed to blue by alkalis; *azolitmin*, brown-red, amorphous, insoluble in alcohol, turned blue by ammonia; and *spaniolitmin*, present in minute quantity only, light-red, soluble in water.

Pharmaceutical Uses.—Litmus is employed as a reagent for acids and alkalies. Litmus-paper is made by making a strong aqueous solution of the coloring matter (*tincture of litmus*), and dipping white unsized paper into it. To make *red litmus-paper*, dilute hydrochloric acid is carefully added to the blue solution until the color has just changed to red, carefully avoiding excess of the acid. When litmus is used for testing by gas-light the change of color is best observed through a green glass. By treating litmus with alcohol, afterward with water, purifying the aqueous extract with alcohol acidulated with acetic acid, and removing every trace of the acid by dissolving in water and evaporating repeatedly with alcohol, nearly pure brown-red azolitmin is obtained, from which test-paper extremely sensitive to both acids and alkalies may be prepared.

Allied Pigments.—Archil or orchil, *E. Orseille*, Fr., G., is made from the same lichens which yield litmus. The lichens are heated for a week with diluted ammonia, when sulphuric acid and table-salt are added. Archil is a pasty mass of a deep-purple color.

Cudbear, *E. Orseille de terre*, Fr., Persio, G., is made in precisely the same manner, except that, instead of adding acid and salt, the mixture is dried and powdered.

The lichens which are used for the production of the above pigments contain a number of chromogenes, which are ternary compounds, and in the presence of water and ammonia are converted into various nitrogenated red pigments. The most important of these chromogenes, as far as they have been investigated, are—*erythric acid*, $C_{20}H_{22}O_{20}$, *alphaorsellie acid*, $C_{32}H_{28}O_{14}$, *betaorsellie acid*, $C_{34}H_{32}O_{15}$, and *evernic acid*, $C_{34}H_{32}O_{14}$. On being boiled for a long time with water or baryta they yield *becanoric acid*, $C_{16}H_{14}O_7$, afterward *orsellie acid*, $C_8H_8O_4$, and finally *orein*, $C_{12}H_8O_2$, which crystallizes in large colorless needles, has a sweet taste, turns red in contact with air, and yields with ammonia *orecin*, $C_7H_7NO_3$; this is brown, and dissolves in alkalies with a beautiful red color. Orein is also obtained from aloes by fusing it with caustic potassa.

Medical Uses.—The only use of litmus in medicine is to determine the acidity or alkalinity of the animal fluids. Litmus-paper is a necessary adjunct of all apparatus for examining the urine.

LACTUCA, Br.—LETTUCE.

Herba lactucæ; *Herba lactucæ virosæ*.—*Laitue vireuse*, Fr.; *Gifflattich*, G.

The flowering herb of *Lactuca virosa*, *Linné*. Woodville, *Med. Bot.*, t. 31; Bentley and Trimen, *Med. Plants*, 160, 161.

Nat. Ord.—Compositæ, Ligulifloræ.

Description.—This biennial herb, which grows to the height of 3 to 6 feet (.9–1.8 M.), has a cylindrical, somewhat prickly, pale-green, and often purplish-spotted stem. The large radical leaves are petiolate, obovate-oblong, obtuse, irregularly spinously toothed, wavy or nearly entire at the margin, pale-green beneath, and prickly on the midrib. The stem-leaves are smaller, alternate, horizontal, sessile, with a sagittate amplexicaul base and an acute spinous apex, otherwise resembling the radical leaves, the floral ones reduced to small pointed bracts. The flower-heads form a loose terminal

panicle and are on short axillary peduncles: the involuere is oblong or conical, and composed of imbricated lanceolate bracts in about three rows; the florets are neutral, pale-yellow, ligulate; the akenes are oval, flattened, black, and prolonged into a long whitish beak, bearing at its apex a pappus consisting of numerous soft white capillary bristles. The plant has a disagreeable rather narcotic odor and a bitter and saline taste.

It is indigenous to Western and Southern Europe, is less frequent in Central Europe, and has been naturalized in some parts of New England. It is closely allied to *L. Scariola*, *Linne*, which is indigenous to Europe, but is found more frequently in the central part, and is distinguished from the preceding mainly by its spinescent, deeply-cut, toothed or pinnatifid vertical leaves, but possesses the same disagreeable odor and taste, though in a rather milder degree.

Constituents.—The older analyses by Pfaff, Dublane, and others have demonstrated the presence of principles common in herbs; among the inorganic constituents potassium nitrate was found by Pfaff and Bley. More recently, the investigations have been confined to lactucarium, which is partly obtained from this plant.

Off. Prep.—*Extractum lactucae*, *Br.*

Medical Action and Uses.—The ancients ascribed to strong-scented lettuce soporific and anaphrodisiac properties, and its juice was even used by them for adulterating opium. It was held to be peculiarly adapted to allay wakefulness produced by overstimulation of the mind. Whatever may have been the virtues of lettuce in ancient Greece, they are certainly very faintly represented by the plant which grows in this country and in Western Europe. They are contained in their most concentrated and available form in lactucarium.

LACTUCARIUM, *U. S.*, *P. G.*—LACTUCARIUM.

Lactucarium, *Fr.*, *G.*; *Gifilattichsaft*, *G.*

The concrete milk-juice of *Lactuca virosa*, *Linne*, obtained by incision and spontaneous evaporation.

Origin and Collection.—*Lactuca virosa* and *L. Scariola*, *Linne*, have been described above. *L. sativa*, *Linne*, is the common garden lettuce. *L. altissima*, *Bieberstein*, a tall Caucasian herb, is cultivated in Auvergne in France for lactucarium; Planchon regards it as a variety of *L. Scariola*, *Linne*. We prepared (1867) very efficient lactucarium from several varieties of *L. canadensis*, *Linne*, of this country, but found the milky juice, which yielded from 22 to 32 per cent. of air-dry residue, to congeal rapidly and to dry into irregular tears. Commerce is supplied with lactucarium almost exclusively from Germany and Great Britain from plants cultivated for the purpose; a small quantity is also produced in Austria. Thomas Fairgrieve, who described the preparation in 1873, states that he cultivates *L. virosa*, var. *montana*. The collection of the milky juice is commenced about the middle of July or beginning of August, when the flowers are just appearing, and is continued for 6 or 8 weeks (until the latter part of September). The collectors proceed over the field, cutting the head of each stalk and scraping the juice into their vessels, one person who cuts being followed by two who collect the juice. This process is repeated six or seven times a day, a new cut being made each time a little lower down the stalk. In the evening, when the juice has thickened into a viscous mass, it is turned out of the vessels, suitably divided, and dried by the aid of heat, about 5 days being required for it.

In Germany, near the town of Zell on the Mosel, the collection lasts from May to September; the milky juice is taken up by the finger and transferred to hemispherical earthen cups, in which it quickly hardens, so that it can be turned out. It is then dried in the sunshine until it can be cut into four pieces, when the drying is completed by exposure to the air for some weeks on frames (*Pharmacographia*).

The lactucarium prepared in France by Aubergier is rarely if ever met with in this country. Fairgrieve obtained 1 pound of lactucarium from 4 pounds of juice, and estimates the average yield of each plant to be between 40 and 50 grains. By frequently puncturing the stems, Schütz (1823) obtained from *L. sativa*, *scariola*, and *virosa*, respectively, 17, 25, and 56 grains of lactucarium. The extract of lettuce-leaves was medicinally employed by Dr. H. J. Collin of Vienna (1780), but lactucarium was first introduced into medicine by Dr. J. R. Coxe of Philadelphia (1799).

Description.—German lactucarium generally comes in sections of plano-convex circular cakes which are of a gray-brown color externally, usually white or yellowish, and of a waxy lustre internally. English or Scotch lactucarium is met with in irregular-sized

angular pieces of a brown color and earthy appearance. Both kinds have a strongly bitter taste and a strong narcotic odor, suggesting that of opium: they are powdered with difficulty, and on trituration with water are not emulsionized, except after the addition of gum-arabic. When lactucarium is prescribed in mixtures, A. Vogeler (1881) recommends triturating it with a little spirit of nitrous ether before adding the water, when it is readily divided in the liquid.

What is usually sold here as French lactucarium is *EXTRACTUM LACTUCÆ* (see p. 644).

Tests.—Lactucarium on being treated with boiling water should become soft without melting, and yield a bitter filtrate, which while hot should be clear, and on cooling become turbid; this liquid should not be colored blue by iodine (absence of starch), but should become clear on the addition of ammonia or of alcohol; the ammoniacal liquid should yield a copious precipitate with solution of calcium sulphate (presence of oxalic acid), and the alcoholic solution should not be affected by ferric chloride (absence of tannin, etc.)—*P. G.*

Constituents.—Lactucarium has been analyzed by Walz (1840), Aubergier (1842), Wackenroder (1844), Lenoir (1847), Ludwig (1847), Kromayer (1861), and O. Schmidt (1875, 1879). Nearly one-half the weight of lactucarium is soluble in alcohol, but dilute alcohol dissolves only between 36 and 44 per cent. 50 to 60 per cent. of lactucarium consists of *lactucerin* or *lactucon*, $C_{16}H_{26}O$, which was obtained crystallized by Lenoir (1847) by exhausting lactucarium with boiling alcohol and recrystallizing the product: it forms thin colorless needles, which are inodorous and tasteless, insoluble in water, soluble in alcohol, and more freely so in ether, chloroform, benzin, and fixed and volatile oils; it appears to vary somewhat in different lactucariums. The bitter taste of lactucarium is due to three principles, two of which are usually amorphous and freely soluble in water, while the crystallizable *lactucin*, $C_{11}H_{12}O_3 \cdot H_2O$, requires over 60 parts of cold water for solution, but dissolves more readily in hot water and in alcohol. Kromayer (1861) obtained only 0.3 per cent., which does not perhaps represent the whole amount present, but the much larger yields (18 to 28 per cent.) previously observed by Buchner and Ludwig must be due to impurities. Lactucin forms pearly scales or rhombic plates when crystallized from very dilute alcohol, has a neutral reaction, turns red and brown with alkalis, and is deprived of bitter taste; it is not a glucoside, but reduces from alkaline cupric solutions cuprous oxide. *Lactucic acid* and *lactucopierin* have been found in the mother-liquor of lactucin; the former is light-yellow, amorphous, crystallizes on long standing, is colored red by alkalis, reduces alkaline copper solutions, is precipitated by lead subacetate, and is insoluble in carbon disulphide, petroleum benzin, ether, and chloroform. Lactucopierin is brown, amorphous, insoluble in ether, soluble in alcohol, not precipitated by subacetate of lead, and appears to be produced by oxidation of lactucin.

The other constituents of lactucarium which have been observed by different investigators are—a trace of volatile oil, asparagin, mannit, sugar, albumen, gum, caoutchouc, resin, oxalic, citric, and malic acids, and between 8 and 10 per cent. of ash. Flückiger obtained from German lactucarium, by means of carbon disulphide, an amorphous mass which is fusible below 100° C. and separates from alcohol as a syrupy liquid.

Hiland Flowers (1879) noticed that the milk-juice of *L. canadensis* does not possess a bitter taste until the plant is in bloom, when the lactucarium collected from it has the same constituents as European lactucarium.

Off. Prep.—*Extract. lactucarii fluid.*, *Syrupus lactucarii*, *U. S.*

Medical Action and Uses.—The utility of retaining lactucarium as an official medicine is very doubtful. It may possibly be desirable as a hypnotic for very impressionable persons, with whom faith in a remedy supplies its want of intrinsic efficiency. If it have any virtues of the sort ascribed to it, they would peculiarly adapt it to cases of infantile disease. The dose of lactucarium is indefinite. 2 grains (Gm. 0.10) may be given to an infant.

LAMELLÆ, *Br.* (see page 1661).

LAMINARIA, *P. G.*—LAMINARIA.

Laminaire digittée, *Fr.*; *Laminaria*, *Riementang*, *G.*

Laminaria Cloustoni, *Edmonston*, s. *L. digitata*, *Lamouroux*.

Nat. Ord.—*Algæ*. *Fucoideæ*.

Origin.—The Linnean name, *Laminaria digitata*, has, according to Ferd. Cohn (1864), been applied to two different *Algæ* which are found in the North Atlantic Ocean. *Laminaria flexicaulis*, *Le Jolis* (s. *L. stenophylla*, *Harvey*), has a glossy, dark-brown, flexible stem, which on drying becomes thin like a fibre. *Laminaria Cloustoni*, however, has an

erect, rigid, light-brown stem, 3 to 6 feet (0.9–1.8 M.) long, at the base 2 inches (5 Cm.) thick, divided below into spreading root-like branches, and at the apex prolonged into a flat and digitately divided frond which is 3 to 5 feet (0.9–1.5 M.) long, 1 to 3 feet (30–90 Cm.) broad, leathery, and olive-green. The plant grows upon rocks at a depth of 10 to 15 fathoms in the Atlantic and Pacific Oceans and northward in the Arctic Sea. The lower cylindrical portion only is employed.

Description.—*Laminaria* is met with in commerce in irregular cylindrical pieces, which are $\frac{1}{2}$ inch (12 Mm.) or less thick, deeply wrinkled, of a brown or gray-brown color externally, lighter and darker brown internally, of a horn-like texture, and breaking with a smooth and horny fracture. Immersed in water, it becomes softer and swells to from four to six times its usual diameter. Two layers are readily distinguished, the central one being whitish and composed of large cells, while the outer one is formed of smaller cells, has a brownish color, and contains a zone of axially somewhat elongated large mucilage-cells. For medical use it is turned into cylindrical or conical pieces.

Constituents.—*Laminaria* contains the usual constituents of marine Algæ. (See CHONDRUS.) Stenhouse isolated from it mannit.

Allied Plants.—*LAMINARIA SACCHARINA*, *Lamouroux*, has a flattish stem and linear or oblong entire fronds. After having been washed with water it acquires a sweet taste, and, like *Lam. esculenta*, *Lamouroux*, is eaten. The ash of all these species is used for obtaining iodine.

For some years past the soft root of one or two species of *tupelo*, *Nyssa* (Nat. Ord. Cornaceæ), has been used in Europe for tents. The species adapted for this purpose are *Nyssa grandidentata*, *Michaux filius*, and *N. capitata*, *Walter* (*N. candicans*, *Michaux*): both grow in the Southern United States not far from the sea-coast. The first species is known as *cotton-gum*, *large tupelo*, and, in Louisiana, *olivier à larges feuilles*; the second species is called *tupelo-gum*, *sour-gum*, and *Ogechee lime*. The wood is light, white, of a spongy texture, and when dry swells to about double its usual thickness from the absorption of water.

Medical Action and Uses.—The porosity of its stalks and the quality they possess, when dried, of absorbing water, and thereby increasing in bulk even as much as four-fold, have rendered *laminaria* a very convenient substitute for compressed sponge. The following summary of the qualities of sea-weed tents, applied particularly to the uterus, was made by Dr. J. Braxton Hicks: 1, they may be made of any size, but much smaller than sponge tents; 2, they have more distending power; 3, they do not retain the secretions so as to produce much offensiveness; 4, by their greater rigidity they can be more readily applied, especially in a tortuous canal. On the other hand, their rigidity makes them less suitable in cases where the uterus readily bleeds or is very tender, and in cases where the os is somewhat dilated by a polypus or growth distending it. For *dilatation of the os uteri* in a natural state, and for the induction of premature labor, these tents are less suitable than sponge tents or the India-rubber bag. In cleanliness, certainty of action, ease of introduction, and small size they are not equalled by those made of any other material. By fastening several together the physician is enabled to effect any degree of dilatation he may desire. They are, however, no less likely than other uterine tents to produce metritis. According to Landau, the *tupelo* tents recommended by Tiemann are superior to any other for the same reasons above assigned in favor of *laminaria* tents (*Times and Gaz.*, Mar. 1881, p. 327). Bougies of *laminaria* have been employed to dilate strictures of the *urethra*. For this purpose they were covered with several coats of varnish or with glycerin before introduction, and allowed to remain in place for several hours. Similar instruments have been made use of for dilating the Eustachian tube.

LAPPA, U. S.—BURDOCK.

Radix bardanæ.—*Bardane*, *Glouteron*, Fr.; *Klettenwurzel*, G.

The root of *Lappa officinalis*, *Allioni* (*Aretium Lappa*, *Linné*, *A. majus*, *tomentosum*, and *minus*, *Schkuhr.*).

Nat. Ord.—*Compositæ*, *Cynaræ*.

Origin.—We follow Gray in uniting the three forms, which are often regarded as distinct, and described as *Lappa major*, *Gaertner*, *L. tomentosa*, *Lamarck*, and *L. minor*, *De Candolle*. They are found in waste places and along roadsides in Northern Asia and throughout Europe, and have been naturalized in North America, where the variety *major* is more frequently met with than the others. They are coarse-looking biennial weeds, with branching stems 2 to 4 or 6 feet (.6, 1.2, or 1.8 M.) high, and cordate-oblong, nearly entire or toothed, rough, petiolate leaves. The globose involucre has the numerous scales

appressed at the base and contracted to a recurved sharp point above. The numerous tubular florets are purplish, or, rarely, whitish; the akenes are flattened and have a pappus of numerous short bristles. The variety major has rather large heads with a smoothish involucre; var. *tomentosa* has the involucre and peduncles woolly; var. *minor* has the heads much smaller, the involucre at first cottony, finally smooth, and the leaves usually unequally rounded or tapering at base. They bloom from July to September. The root should be collected in the autumn of the first year's growth or early in the succeeding spring; 6 or 7 parts of the fresh yield 1 part of air-dry root.

FIG. 171.

Burdock-Root: transverse section.

radially striate and by a dark cambium-line separated from the medullium; this is about four times thicker, has finely porous ligneous rays, and the medullary rays of about the same width. The latter, as well as the parenchyma of the bark, are frequently partly destroyed, leaving merely the white dead tissue, which is spongy and full of holes. Burdock has a rather disagreeable but weak odor, and a mucilaginous afterward sweetish and bitterish taste.

Constituents.—Burdock-root is free from starch, but contains in its stead *inulin*. (See *INFULA*.) Mucilage, sugar, a bitter principle, a little resin, and some tannin have been observed in it.

Allied Drugs.—*FRUCTUS LAPPÆ*, S. *SEMEN BARDANÆ*. Burdock-fruit is about $\frac{1}{4}$ inch (6 Mm.) long, obovate-oblong, somewhat curved, angular, and flattened, roughish wrinkled, brown-gray mottled with black, mostly deprived of the setaceous pappus, the short base of the style projecting from the centre of the apical scar; inodorous; taste oily and bitter. The bitter principle has not been isolated. *Tinctura lappæ fructus* has been proposed to be made from 4 troyounces of the ground fruit by percolating with a mixture of alcohol 3 parts and water 1 part until a pint of percolate is obtained.

FRUCTUS SILYBI, S. *SEMEN CARDUI MARIE*.—Mary thistle, *E.*: Chardon Marie, *Fr.*: Stechkörner, Frauendistel, *G.*—from *Silybum marianum*, *Gærtner*, s. *Carduus marianus*, *Linne*, a syngenesious biennial of Southern Europe. The akenes are $\frac{1}{4}$ or $\frac{1}{5}$ inch (4 or 5 Mm.) long, not curved, obovate, flattened, smooth, glossy, light-brown with black or blackish striae, oblique at the apex, and crowned by a yellowish margin, from the centre of which the base of the style projects; inodorous; taste mucilaginous, oily, and somewhat bitter.

Medical Action and Uses.—Burdock has had the reputation in Europe and in this country of being a depurative through its diaphoretic and diuretic virtues, and by a gradual and insensible modification of nutrition. It has been in vogue for the cure of *rheumatism*, *gout*, chronic *cutaneous diseases*, and chronic *pulmonary catarrhs*; it has been reputed to be diuretic (especially its seeds), and to promote the discharge of *urinary deposits*; to be alterative also, and beneficial in constitutional *syphilis* and *scrofula*. These virtues, if they are real, would indicate that the medicine operates by promoting all the secretions, much as sarsaparilla is supposed to do. But, like that medicine, burdock is seldom given unless associated with more active agents. Externally, the expressed juice of the leaves, the fresh leaves bruised, and liniments made by boiling the leaves or the roots with oil have been much used as popular remedies for *burns*, *wounds*, *ulcers*, and *eruptions*. Although an agent of secondary value, it is not quite just, as has been done, to call it "one of the illusions of the materia medica." Burdock is generally given in a decoction prepared by boiling 2 ounces of the recent bruised root in 3 pints of water (Gm. 64 in Gm. 1500) to 2 pints. At least a pint (Gm. 500) of this decoction should be taken daily. Possibly the concentrated syrup or fluid extract, equally diluted, would answer quite as well. According to Dr. Squibb, a tincture made with 1 pound of the ground seed to a gallon of whisky, and allowed to stand for 2 weeks before decanting, may be taken in *doses* of 2 or 3 teaspoonfuls immediately after meals. He cites a case in which a similar preparation cured an inveterate *psoriasis* (*Ephemeris*, Sept. 1882, p. 115).

LARICIS CORTEX, *Br.*—LARCH-BARK.

Ecorce de mélèze, Fr.; Lärchenrinde, G.

The bark, deprived of its outer layer, of *Larix europæa*, *De Candolle* (*Abies Larix*, *Richard*, *Pinus Larix*, *Linne*).

Nat. Ord.—Coniferæ, Abietinæ.

Origin.—The European larch is a forest tree of Southern and Central Europe, where it grows chiefly in mountainous localities up to an altitude of about 5000 feet (1500 M.). It is often cultivated in Europe, and has been introduced into North America as an ornamental tree. It attains a height of 80 to 100 feet (24–30 M.), has the narrow linear deciduous leaves in fascicles of twenty to forty, and oblong ovoid erect cones which are about 1 inch (25 Mm.) long. The bark is collected from the trunk and the branches.

Description.—The bark has a brown-gray, or when older a reddish-brown, fissured, corky layer, which is to be removed. The liber has a reddish or pinkish hue; the inner surface is smooth, of a yellowish or pale-brown color. It breaks with a short somewhat fibrous fracture, displaying rather indistinct medullary rays and some resin-ducts. Larch-bark has an agreeable terebinthinate odor and a balsamic and astringent taste.

Constituents.—Stenhouse (1861) found larch-bark to contain a good deal of peculiar *tannin*, which yields olive-green precipitates with salts of iron, turns red on being boiled with dilute sulphuric acid, but does not yield any *sugar*, which, however, is contained in the decoction of the bark, together with a considerable quantity of *mucilage* and *resinous matter*. He obtained also a volatile acid by evaporating the warm infusion of the bark to a syrupy consistence and then distilling it. The *larixinic acid*, $C_{10}H_{10}O_5$, crystallizes partly in the neck of the retort; the remainder is obtained by carefully concentrating the distillate and purifying the product by sublimation. The bark of the branches and of trees not over 30 years old yields the largest proportion. It forms long colorless crystals resembling those of benzoic acid, sublimes at 93° C. (199.4° F), fuses at 150° C. (302° F.), and has a bitterish and astringent taste and a camphoraceous odor. Its combinations with alkalis are red-brown and decomposed by carbonic acid; baryta solution causes a bulky precipitate; ferric salts produce a purple color, and on boiling it with silver salts the metal is separated; nitric acid oxidizes it to oxalic acid. It is sparingly soluble in ether and freely soluble in alcohol and hot water. It is allied to pyrogallie acid and pyrocatechin.

Other Products of the Larch are Venice turpentine and Briançon manna.

The bark of the American larch, *Larix americana*, *Michaux*, which is more slender and has shorter leaves and smaller cones, deserves to be investigated.

Off. Prep.—Tinctura laricis, *Br.*

Medical Action and Uses.—Its action does not differ from that of other terebinthinate and balsamic remedies, but its flavor is less disagreeable. With the inner bark a saturated tincture has been prepared, and highly recommended in *chronic bronchitis* and in chronic inflammation of the *urinary mucous membrane*. It has also been used in *purpura hæmorrhagica*. The dose of the tincture is from 20 to 30 minims (Gm. 1.30–2).

LAUROCERASI FOLIA, *Br.*—CHERRY-LAUREL LEAVES.

Folia laurocerasi.—Feuilles de laurier-cerise, *Fr.*; Kirschlorbeerblätter, *G.*

The fresh leaves of *Prunus Laurocerasus*, *Linne* (*Cerasus Laurocerasus*, *Loiseleur*). *Steph.* and *Church*, *Med. Bot.*, plate 117; *Bentley* and *Trimen*, *Med. Plants*, 98.

Nat. Ord.—Rosaceæ, Amygdalæ.

Origin.—The cherry-laurel is a small evergreen tree, or is frequently a shrub 15 to 20 feet (4.5–6 M.) high, with a smooth brownish bark and pale-green branches, and produces pendulous racemes of dark-purple, shining, cherry-like drupes. It is a native of Western Asia from Northern Persia to Asia Minor, but it has been naturalized in Southern Europe, and is cultivated in the open air as an ornamental shrub northward to Southern Germany and England.

Description.—The leaves are leathery, glossy, and dark-green above, pale-green beneath, oblong in outline, narrowed above to an obtuse point and below to a short petiole. They are about 4 to 6 inches (10–15 Cm.) long and 1½ to 2½ inches (38–62 Mm.) wide, somewhat revolute on the margin, with distant and small but sharp serratures. The midrib is quite prominent on the lower surface, and has near its base one or two pairs of

depressed glands. The unbroken fresh leaves are inodorous, but when broken they have a strong bitter-almond odor: their taste is aromatic, bitter, and somewhat astringent.

Constituents.—Cherry-laurel leaves contain some sugar, tannin, wax, fat, and, according to Stange (1823), an acid allied to, if not identical with, malic acid. The same author recognized also the production of *benzoic acid* from the volatile oil in the presence of oxygen. Liebig and Wöhler did not succeed in isolating amygdalin, from which they suppose the volatile oil to be derived. F. L. Winckler (1839) obtained the bitter principle as a soft, transparent, wine-yellow mass, which, when treated with dilute sulphuric acid and manganic binoxide, yielded a distillate of a very agreeable odor which did not contain hydrocyanic acid. When treated with emulsion of sweet almonds the taste became gradually less bitter, and the odor of bitter almonds became afterward apparent. It seems, therefore, as if the leaves contained a compound from which amygdalin must be first produced before the volatile oil can be obtained, which has the same composition as oil of bitter almonds. Broeker (1867) observed that the watery distillate is strongest in hydrocyanic acid if the leaves were collected in the summer. Schoonbroodt (1869) obtained from the aqueous extract, on treatment with ether, some bitter crystals which reduced cupric oxide.

Off. Prep.—Aqua laurocerasi, Br.

Medical Action and Uses.—Cherry-laurel leaves are officinal in the British Pharmacopœia, chiefly as the source from which cherry-laurel water is obtained. Their medicinal virtues depend upon the hydrocyanic acid which they furnish, and are treated of under AQUA LAUROCERASI and ACIDUM HYDROCYANICUM. The bruised fresh leaves are used as anodyne applications to *painful parts*.

LAURUS.—LAUREL.

Bay, Sweet bay, E.; Laurier commun, Fr.; Lorbeer, G.

European pharmacopœias recognize the leaves, fruit, and expressed oil of *Laurus nobilis*, Linné. Bentley and Trimen, *Med. Plants*, 221.

Nat. Ord.—Lauraceæ.

Origin.—The bay tree is indigenous to the Levant and grows wild in the countries bordering the Mediterranean. It is a small tree or large shrub with umbellate clusters of yellowish flowers.

Description.—1. FOLIA LAURI. They are 3 or 4 inches (7–10 Cm.) long, an inch (25 Mm.) or more broad, shortly petiolate, coriaceous, smooth, pellucid-punctate, oblong or oblong-lanceolate, rather acute at both ends, entire, glossy above and veined beneath. The veins form, with the midrib, an acute angle, send off numerous lateral branches forming a network of small meshes, and disappear near the margin of the leaf without prominently anastomosing. The dry leaves are of a yellowish- or brownish-green color. They have a pleasant aromatic odor and an aromatic and bitterish taste.

2. FRUCTUS (BACCÆ) LAURI. *P. G.* The so-called *bay-berries* are oval or subglobular drupes about $\frac{1}{2}$ to $\frac{3}{4}$ inch (8–13 Mm.) long. When dry, they are greenish-black or blackish-brown, slightly wrinkled, and fragile, the integuments, including the reddish-brown endocarp, being thin and brittle. The loose oval seed is easily separated into the two plano-convex brownish cotyledons, which have an aromatic oily and bitter taste.

3. OLEUM LAURI (S. LAURINUM, S. LAURI EXPRESSUM, S. LAURI UNGUINOSUM). *P. G.* It is obtained in Southern Europe by expressing the bruised fruit between warm plates after steeping it in hot water. It has the consistence of lard, a granular appearance, a green color, and an aromatic odor and taste. It melts near 40° C. (104° F.) to a clear dark-green liquid, is soluble in ether, partly soluble in alcohol, and does not yield its coloring matter to water. When agitated with warm alcohol the alcoholic solution should not become red on the addition of ammonia (absence of turmeric). Fictitious oils, if colored with curcuma and indigo, leave these behind when dissolved in ether.

Constituents.—The leaves and fruit contain a volatile oil. The volatile oil of bay-berries is pale-yellow, of the spec. grav. 0.91, congeals at a low temperature, contains oxygen, and is easily soluble in alcohol; it contains hydrocarbons, $C_{10}H_{16}$, boiling at 171° C. (340° F.) and 250° C. (482° F.), and four oxygenated constituents (Staub). Gladstone (1863) had found eugenol, while Blas (1865) could not detect this, but proved the presence of a little lauric acid. Bley (1834) obtained from old berries .22 per cent. of volatile oil. The seeds contain, according to Bonastre (1824), about 20 per cent. of fat, 2 per cent. of volatile oil, and 1.5 per cent. of resin. The expressed fat was analyzed by A. Staub (1879), who determined, besides volatile oil and chlorophyll, the presence

of a little acetic acid and the glycerides of oleic, linoleic, lauric, myristic, palmitic, and stearic acids. *Lauric acid*, $C_{12}H_{24}O_2$, discovered by Marsson (1842), has been found in many vegetable and a few animal fats; it melts at $43.5^\circ C.$ ($110.3^\circ F.$), and volatilizes with the vapors of boiling water (Goergey, 1848). Schmidt and Roemer found little free acid in the freshly-expressed oil, but the fruit contained 2 to 3 per cent. of fatty acids.

Medical Action and Uses.—Bay leaves and berries were anciently held in high esteem as stimulant, stomachic, and astringent, and in substance or decoction were much used for the stings of insects, eruptions of the scalp, and vaginal relaxation with leucorrhœa; a decoction of the root-bark was given internally in diseases of the urinary organs and in dropsy, and was regarded as a powerful emmenagogue. More efficient medicines have supplanted it, and it is now seldom used except in the form of its volatile and fixed oils for relieving *local rheumatic* and other *pains*. In Europe the fresh leaves continue to be employed for flavoring pastry and rendering it more digestible.

LAVANDULA, U. S.—LAVENDER.

Flores lavandulæ, P. G.; *Flores lavendulæ*.—Lavender-flowers, E.; *Fleurs de lavande*, Fr.; *Lavendelblüthen*, G.

The flowers of *Lavandula vera*, *De Candolle* (*L. Spica*, var. *a*, *Linne*; *L. angustifolia*, *Ehrhart*; *L. officinalis*, *Chaix*). *Bentley and Trimen, Med. Plants*, 199.

Nat. Ord.—Labiata, Ocymoiidæ.

Origin.—Lavender is a native of Southern Europe from Italy to Spain, and of North-western Africa, growing upon sunny hillsides and mountains. It is extensively cultivated as an ornamental garden-plant, and in Europe also for the purpose of distilling the volatile oil. (For an account of the cultivation of lavender at Hitchin, England, see *Proc. Amer. Phar. Assoc.*, 1876, pp. 819–821.) The plant is shrubby, about 2 feet (60 Cm.) high, has a brown-gray bark, which is much cleft when old, opposite, sessile, entire, and linear leaves, with revolute margins and long-stalked terminal spikes, with the lower whorls of flowers remote from the others. The flowers are collected in June and July before fully expanded, and require to be carefully dried.

Description.—The flowers grow in the axil of rhombic-obovate, pointed, brownish, and glandular bracts of nearly the length of the calyx. The latter is about $\frac{1}{4}$ inch (4 Mm.) long, tubular, thirteen-nerved, contracted and naked at the mouth, with the upper tooth roundish-rhomboid and the remaining four teeth obsolete, densely covered with short hairs and minute glands, and of a blue-gray color. The corolla exceeds the calyx, and is violet-blue, tubular, enlarged above, hairy and glandular on the outside, and two-lipped, the upper lip being erect and two-lobed, and the smaller lower lip spreading and three-lobed. The four stamens are quite short and inserted in the middle of the hairy corolla-tube. Lavender-flowers have an agreeable aroma, which becomes more apparent on bruising and rubbing them, and a bitterish aromatic somewhat camphoraceous taste.

Constituents.—Besides some tannin, resin, and other widely-diffused principles, lavender-flowers contain volatile oil, when fresh yielding about 1 per cent. (See *OLEUM LAVANDULÆ*.)

Allied Plants.—*LAVANDULA SPICA*, *Chaix*, s. *L. LATIFOLIA*, *Ehrhart*.—Spike lavender, E.; *Aspic*, *Lavande mâle*, Fr.; *Spiklavendel*, G.—The plant has spatulate leaves, rather short and dense spikes, and lance-linear bracts. The calyx is finely velvety-hairy, not blue, and about the same length as the calyx-tube. The plant is cultivated in Southern France and Northern Africa, and volatile oil is distilled from it.

LAVANDULA STOECHAS, *Linne*.—Arabian or French lavender, E.; *Stœchas*, Fr.; *Schopflavendel*, G.—This small shrub grows near the Mediterranean, where the flowering spikes are used. These are short-stalked, about $\frac{1}{4}$ inch (2 Cm.) long, and have the small dark-purple flowers in the axil of conspicuous rhombic or obovate, sometimes three-lobed, purple-colored bracts; the odor is strongly aromatic, camphoraceous.

OCYMMUM BASILICUM, *Linne*.—Sweet basil, E.; *Grand basilic*, Fr.; *Basilienkraut*, G.—This annual herb is indigenous to tropical Asia and Africa, and is frequently cultivated in gardens.

FIG. 172.

Lavender-flower, with bract and corolla cut open; magnified 4 diameters.

The branching and more or less pilose stem is 1 to 2 feet (30-60 Cm.) high; the long petiolate leaves are oblong-ovate, somewhat toothed, smooth, and beneath glandular-punctate; the flowers are in somewhat interrupted spikes, the calyx short and ciliate, and the corolla white or reddish, with a short tube, a broad four-lobed upper lip, and a descending spatulate lower lip. The herb has a strong and agreeable aromatic odor and a balsamic and cooling taste; it contains volatile oil and a little tannin.

Medical Action and Uses.—Lavender is a stimulant aromatic, remarkable for its refreshing perfume. It is seldom used internally, unless in the form of oil or spirit, and then associated with other medicines. The infusion (5j to 0j — Gm. 4 to Gm. 60) is said, when too freely taken, to occasion colic. Fomentations made with lavender enclosed in bags allay *local pains*, like other plants of the Labiate family.

Ocimum basilicum (basil or sweet basil) is a well-known potherb used for seasoning certain kinds of food, and has the same general qualities as thyme, sage, etc. It has long been a popular remedy for mild nervous or hysterical disorders, and in Buenos Ayres its fresh juice is said to be used as an anthelmintic, and to possess the advantage of not tending to produce unpleasant symptoms. Its essential oil was formerly in vogue as a carminative and nervine (*Med. Record*, xvi. 325).

LEDUM.—MARSH TEA.

Marsh cistus, Wild rosemary, E.; *Lédon*, *Romarin sauvage*, Fr.; *Porsch*, *Sumpfporst*, *Wilder Rosmarin*, G.

The leaves of *Ledum palustre*, *Linné*.

Nat. Ord.—Ericaceæ, Ericineæ.

Origin.—This shrub flourishes in marshy locations in the northern sections of North America, Asia, and Europe. It is about 3 feet (90 Cm.) high, and has white or pale rose-red five-petalled flowers in umbellate clusters.

Description.—The leaves are coriaceous, about an inch (25 Mm.) long, linear or lance-linear, obtuse, with a revolute margin, dark-green, smooth, glossy, and with depressed veins above, and clothed with a rusty wool on the lower side. They have a peculiar heavy aromatic odor and a bitter aromatic somewhat camphoraceous taste.

Constituents.—Meissner's results (1827) with marsh tea were further investigated by Willgik (1852) and others. The tannin, *leditanic acid*, $C_{15}H_{20}O_8$, is a reddish powder which dissolves in water and alcohol and colors ferric salts dark-green. The volatile oil, $\frac{3}{4}$ to $1\frac{1}{2}$ per cent., is obtained from plants grown in swampy localities; it is yellow, pungently aromatic, and contains a stearopten, *ledum camphor*, probably $5C_{10}H_{16} \cdot 4H_2O$, which has been examined by Grassmann (1831), Buchner (1856), Trapp (1869), Iwanow (1876), and by Hjelt and Collan (1882); it is in silky needles, sublimable, melts at 101° C. (213.8° F.), and boils at 174° C. (345.2° F.). Fröhde (1861) recognized in the volatile oil the presence of valericianic and other volatile acids, and of *ericinol*, $C_{15}H_{20}O$; this is likewise contained in other ericaceous plants or obtainable from them as a decomposition-product of the glucoside *ericolin*, $C_{31}H_{36}O_{21}$, which was discovered by Rochleder and Schwarz (1852), and is inodorous, hygroscopic, brown-yellow, bitter, soluble in water, alcohol, and alcoholic ether, nearly insoluble in ether, chloroform, and benzin, and not precipitated by lead salts. Thal (1883) gives to ericolin the formula $C_{30}H_{36}O_{23}$, and to ericolol $C_{20}H_{26}O$; combining with water, the latter forms *hydroericinol*, $C_{30}H_{40}O_4$, which is a thick, brown-yellow, balsamic, not bitter fluid. Thal obtained ericolin from over thirty species of Ericaceæ. The remaining constituents of marsh tea are citric acid, resin, wax, and other ordinary vegetable principles.

Allied Plants.—*LEDUM LATIFOLIUM*, Aiton, known as *Labrador tea* and *James tea*, is indigenous to the Northern United States and to British America. The leaves resemble the preceding, but are broader, elliptic-oblong, and occasionally slightly heart-shaped at the base. They probably contain the same constituents.

ANDROMEDA POLIFOLIA, Linné, indigenous to marshes of Northern Asia, Europe, and America, is also known as *wild rosemary*. The leaves are about an inch (25 Mm.) long, linear-lanceolate, acute, strongly revolute at the margin, greenish-white beneath, not aromatic, of a somewhat acrid taste; otherwise resembling the preceding. They are considered to possess acrid and somewhat narcotic properties.

Medical Action and Uses.—This plant has been ranked with acrid-narcotic medicines, and is stated, in large doses, to occasion headache, restlessness, sleeplessness, dyspnoea, cough, dilatation of the pupils, a sort of intoxication, with pain in the limbs, increased secretion of urine, saliva, and especially of sweat, with itching and an eruption

of papules or pustules on the skin. It is said to have been used in the manufacture of beer to render it more intoxicating. It was formerly employed in diarrhœa, dysentery, whooping cough, croup, gouty and rheumatic pains, and all sorts of chronic cutaneous eruptions. Its use for such purposes is, however, obsolete. The *dose* is stated to be from 5 to 15 grains (Gm. 0.30–1). An infusion may be prepared with from 5 to 10 parts of the leaves in from 100 to 200 parts of hot water. A strong decoction of the plant is used to destroy *cutaneous parasites* in horses and neat cattle and to cleanse bedsteads of *vermin*, and the leaves and twigs of the fresh plants are laid among woollen clothing to protect it against moths.

LEONURUS.—MOTHERWORT.

Agripaume, *Cardiaque*, Fr.; *Herzgespann*, *Wolfstrapp*, G.

Leonurus Cardiaca, Linné.

Nat. Ord.—Labiatae, Stachydeæ.

Description.—Motherwort is a perennial herb growing in waste places and near dwellings throughout Europe, Northern Asia, and North America. It is 3 or 4 feet (.9 or 1.2 M.) high, and has a quadrangular rather rough stem. The lower leaves are roundish, often heart-shaped at the base, and palmately five- to seven-lobed; the upper ones are oblong, acutely three-lobed, and have a wedge-shaped base. The pale-purplish flowers have awl-shaped or spiny-toothed calyx-teeth, and are in dense axillary cymes. The plant has a rather unpleasant aromatic odor and a bitter taste.

Constituents.—It evidently contains volatile oil; the bitter principle has not been isolated.

Allied Plants.—Of the numerous plants belonging to the tribe Stachydeæ, the following seem to deserve a brief notice (see also MARRUBIUM and SCUTELLARIA):

STACHYS PALUSTRIS, Linné.—Hedge nettle, *E.*; *Ortie rouge*, *Fr.*; *Stinknessel*, *Sumpfsiest*, *G.*—grows in wet places in Europe and North America. The stem is stiff-hairy. The leaves are mostly sessile, about 3 inches (7 Cm.) long, varying between ovate and linear-lanceolate, round or heart-shaped at the base, rather obtuse, hairy, and on the margin crenately serrate. The flowers are in whorls of six to ten, have sharply subulate calyx-teeth, and a purple somewhat spotted corolla.

BETONICA OFFICINALIS, Linné.—Wood-betony, *E.*—is a native of Southern Europe and grows sparingly in Massachusetts. It is rough-hairy, has cordate-oblong leaves, the cauline ones few, and purplish or whitish soft-hairy flowers in whorls of six to ten.

GALEOPSIS TETRAHIT, Linné.—Hemp nettle, *E.*; *Chanvre batard*, *Galeopside*, *Fr.*; *Hanfnessel*, *Hohlzahn*, *G.*—Introduced from Europe into North America. The stem is densely bristly-hairy below the joints; the leaves are about 2 inches (5 Cm.) long, ovate, usually acute, rather rounded at the base, coarsely serrate. The flowers are in dense axillary clusters, have long spiny-toothed calyx-teeth, and a white or yellowish corolla, with a purple spot on the lower lip.

The allied species, *Gal. ochroleuca*, *Lamarck*, and *G. grandiflora*, *Roth*, at one time attracted attention in Europe as the principal ingredients of a nostrum sold as *Blankenheim tea* or *Lieber's consumption herbs*: the former species is the *Herba galeopsidis* of European pharmacopœias.

BALLOTA NIGRA, Linné.—Black horehound, *E.*; *Marrube noir* (fétide), *Fr.*; *Schwarzer Andorn*, *G.*—Sparingly naturalized in New England. The stem is hairy, often red-brown; the leaves are about 1½ inches (2 Cm.) long, wrinkled, hairy, ovate, slightly heart-shaped, acute, and crenately toothed. The reddish-purple flowers are in axillary clusters of five to nine.

LAMIUM ALBUM, Linné.—Dead nettle, *E.*; *Ortie morte*, *Fr.*; *Taubnessel*, *G.*—It has likewise been introduced from Europe; has ovate, heart-shaped, pointed, and coarsely serrate, somewhat hairy, petiolate leaves, and white or whitish flowers in dense axillary clusters and with slender calyx-teeth. *Lamium amplexicaule*, Linné, and *L. purpureum*, Linné, are more frequent in the United States; they have roundish leaves and smaller purplish flowers.

Many other species of the above genera have been employed in Europe and Asia, and, like the above, contain volatile oil and a bitter principle.

Medical Action and Uses.—A decoction of motherwort is sometimes used in Europe to promote digestion and quicken the functions of the skin. There also *L. lanatus* is regarded as a vascular stimulant and diuretic and as a general tonic; it is employed in *dropsy*, especially of hepatic origin, and is stated to impart to the urine a dark-brown color; it is also used in chronic *gout* and *rheumatism* and to relieve *uterine obstructions*. A hot infusion may be prepared with ½ ounce to 1 ounce of the plant to a pint of water (Gm. 16–32 in Gm. 500).

LEPTANDRA, U. S.—LEPTANDRA.

Culver's Root, *Culver's Physic*, *Black-root*, *E.*; *Racine de leptandra*, *s. de véronique de Virginie*, *Fr.*; *Leptandra-Wurzel*, *G.*

The rhizome, with the rootlets, of *Leptandra virginica*, *Nuttall* (*Veronica virginica*, *Linneé*). Bentley and Trimen, *Med. Plants*, 196.

Nat. Ord.—Scrophulariaceæ.

Origin.—*Leptandra* is indigenous to Canada, and to the United States as far west as the Mississippi Valley; in its southern locations it grows in mountain-valleys, and farther north in low grounds and rich woodlands. It sends up an obtusely-angular stem, 3 to 6 feet (0.9–1.8 M.) high, has the short-petioled, lanceolate, and serrate leaves in verticils of four or five, and the white flowers with the two much-exserted stamens in panicle spikes 3 to 6 inches (7–15 Cm.) long. It flowers in July and August, and produces ovate, two-celled, and many-seeded capsules.

Description.—The rhizome is 4 to 6 inches (10–15 Cm.) long, and about $\frac{1}{4}$ inch (6 Mm.) thick, horizontal, somewhat bent, and branched, blackish-brown to brown-black,

FIG. 173.

Leptandra virginica: transverse sections of rhizomes and rootlets.

nearly free from wrinkles, but the bark is sometimes transversely fissured. The upper side has short remnants of the stems or cup-shaped scars $\frac{3}{4}$ to 2 inches (2–5 Cm.) apart; the numerous rootlets, which are chiefly attached to the lower side, are blackish, about $\frac{1}{16}$ inch (1.5 Mm.) thick, longitudinally wrinkled, quite fragile, and therefore usually detached and much broken. The rhizome is hard, and breaks with a woody fracture, showing a large purplish-brown pith and a few medullary rays dissecting the yellowish wood, which is eight to ten times thicker than the blackish-gray

bark. The ligneous cord of the rootlets is of about the same thickness as the bark. *Leptandra* has no odor; its taste is bitter and feebly acid.

Constituents.—According to the analysis of Prof. Wayne (1856), *leptandra* contains, besides widely-diffused principles, like tannin, gum, resin, and a trace of volatile oil, a principle having the nauseous bitter taste of the drug, and therefore deserving to be called *leptandrin*. It is soluble in water, alcohol, and ether, and was obtained by precipitating the infusion with subacetate of lead, removing the excess of lead from the filtrate by sodium carbonate, and passing the liquid through a column of animal charcoal; this was washed with water and then treated with boiling alcohol, and the extract left on evaporation treated with ether; on evaporating the ether spontaneously a portion of *leptandrin* crystallized; the remainder was contaminated with coloring matter, which prevented it from crystallizing. The so-called *leptandrin* of the eclectics, which is obtained by precipitating the concentrated tincture with water, appears to owe its efficacy to the accidental presence of the principle described. From the mother-liquor of this eclectic preparation Wayne (1859) obtained *mammil.* F. F. Mayer (1863) observed the bitter principle to be at least partly precipitated by tannin, and that portion to be a glucoside; he also found *saponin*, some *citric acid*, and a small quantity of a *volatile alkaloid*. Prof. Lloyd (1880) reported the presence of a considerable amount of glucose, and that the bitter taste of the tincture is destroyed by boiling with dilute sulphuric acid.

Off. Prep.—Extract. *leptandræ*, Extract. *leptandræ fluidum*, *U. S.*

Medical Action and Uses.—Although this medicine has long been in use and is official, we do not learn that it has commended itself to educated physicians by its peculiar virtues, although they are sufficiently marked to merit greater attention. The root, when fresh or recent, acts violently as an emeto-cathartic, and the impure resin obtained from it, and ignorantly called *leptandrin*, as if it were itself the proximate active principle of the plant, produces similar effects when the dose is excessive. Like all gastro-intestinal irritants, it probably promotes the secretions of the mucous glands, the pancreas, and the liver, but has no specific influence upon the last-named organ, as has been confidently assumed. According to Rutherford, its stimulant action on the liver is "very feeble," and it resembles *podophyllin* in its operation. The dose of the powder is stated to be from 20 to 60 grains (Gm. 1.30–4), and of *leptandrin* from 2 to 4 grains (Gm. 0.10–0.20). It has also been given in tincture and fluid extract.

LEVISTICUM.—LOVAGE.

Radix levistici, P. G.—*Liveche*, *Ache de montagne*, Fr.; *Liebstockel*, G.

The root of *Levisticum officinale*, *Koch*, s. *Ligusticum Levisticum*, *Linneé*.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—*Lovage* is indigenous to the mountainous districts of Southern Europe, and has a stem about 4 feet (1.2 M.) high, terminal umbels of yellow flowers, and elliptical or

oval fruits with winged ribs, and one or more oil-tubes in each groove. The plant is sometimes cultivated in gardens.

Description.—The root is altogether about 16 inches (40 Cm.) long, 1 or 1½ inches (25–38 Mm.) thick, several-headed, indistinctly annulate, longitudinally wrinkled, somewhat branched below, and is yellowish-brown externally and pale-yellowish internally. It has a thick bark, which is radially striate from the medullary rays, fissured in the outer portion, and contains numerous orange-yellow resin-cells arranged in irregular concentric circles. The medullium is denser, but soft, and has narrow medullary rays and in the upper portion a central pith. It has a strong balsamic odor, somewhat resembling that of angelica, and a mucilaginous, aromatic, and pungent taste.

The root of *Ligusticum actæifolium*, *Michaux*, which is indigenous to the Southern United States, is similar in appearance and properties.

Constituents.—Lavage was analyzed by Trommsdorff (1836), Riegel (1840), and others, and found to yield a thickish volatile oil containing much stearopten, various resins, some soft, others hard (one having a bitter and pungent taste), sugar, mucilage, and other common principles.

Allied Drugs.—*PIMPINELLA SAXIFRAGA* and *P. MAGNA*, *Linné*, *Radix pimpinellæ*, *P. G.*—Small burnet saxifrage, *E.*: Grand boucage, *Fr.*: Pimpinell, *Bibernell*, *G.*—Indigenous to Europe and Asia. The root resembles the preceding, but is brown-yellow or blackish, usually one-headed, not over $\frac{3}{8}$ inch (15 Mm.) thick, finely annulate above and wrinkled and verrucose below; the bark is very thick, spongy, either white or yellowish, contains numerous resin-cells (in the medullary rays), and encloses a porous radiate yellow wood. The constituents are similar to those of the preceding.

TINCTURA PIMPINELLÆ, *P. G.*, is made with 1 part of the root to 5 parts of alcohol sp. grav. .892. *LASERPITIUM LATIFOLIUM*, *Linné*.—The root was formerly known as *Radix gentiane alba*, from its resemblance in shape to that of gentian-root, but it is externally brownish-white, internally white, and contains yellow resin-cells in the thick spongy bark. Kütz (1883) isolated from it bitter *laserpitin*, $C_{15}H_{22}O_4$, which separates from hot benzol in monoclinic crystals, and is easily soluble in chloroform, ether, benzol, and carbon disulphide.

PEucedANUM OFFICINALE, *Linné*.—The root is externally blackish, internally brownish-yellow, and has a rather thick bark containing numerous orange-colored resin-cells in radial rows, and enclosing a soft porous wood, with resin-cells in the medullary rays. (For *peucedanin*, see p. 813.)

Medical Action and Uses.—Levisticum belongs to the large class of plants containing an essential oil and a resin, which have always been employed as carminatives, diuretics, emmenagogues, and digestive stimulants. It has been much used in flatulent *dyspepsia*, *amenorrhœa*, and *dropsy*, especially in Germany, where it is prescribed as a substitute for angelica. It is administered in decoction or infusion (Gm. 5–10 in Gm. 100), in tablespoonful doses. *Pimpinella saxifraga* is endowed with similar properties, and was formerly much used to expel the mercury remaining in the system after the treatment of syphilis. The root of *Laserpitium latifolium* is an active cathartic. *Peucedanum officinale* was in ancient, and even in modern times, employed as a diuretic, aromatic, and nervine medicine.

LIATRIS.—LIATRIS.

Nat. Ord.—Compositæ, Eupatoriæ.

Description.—The genus *Liatris* embraces principally North American perennial herbs with tuberous roots, simple and erect stems, alternate and entire leaves, and handsome rose-purple flower-heads with an oblong imbricate involucre, naked receptacle, and a pappus composed of many bristles. The flowers are usually in terminal spikes or racemes.

LIATRIS SPICATA, *Willdenow*. The tuberous rhizome is known as *Button snake-root*, *Devil's bit*, and *Colic-root*. It is $\frac{1}{2}$ inch (12 Mm.) or more in diameter, somewhat tuberculate from short branches, and marked with several cup-shaped stem-scars. It is slightly wrinkled and of a brown color externally, and internally of a dingy white, with streaks of brown. Its odor is somewhat balsamic and its taste warm and bitterish.

L. SQUARROSA, *Willdenow*, and *L. SCariosa*, *Willdenow*, are known as *Rattlesnake's master*. The rhizomes resemble the preceding, but are more elongated, irregularly ovate, and beset with a few wiry rootlets. Internally they are of a brownish color.

L. ODORATISSIMA, *Willdenow*, *Vanilla-plant* or *Deer's tongue*. The radical leaves are obovate-spatulate, obtuse, about seven-veined, narrowed below; the stem-leaves are oval or oblong, and clasping at the base. All the leaves are rather fleshy, pale-green, and smooth, and after drying have a very agreeable odor.

Constituents.—The rhizomes appear to contain volatile oil and resin. The leaves of the deer's tongue were found by Procter (1859) to contain coumarin, which is frequently separated upon the surface in crystals.

Pharmaceutical Uses.—Their agreeable and persistent odor renders deer's tongue leaves serviceable in the preparation of sachet powders, etc., as suggested by Dr. A. W. Miller (1875).

Medical Action and Uses.—*L. spicata* is one of the numerous "snake-roots," which owe whatever virtue they possess to being diaphoretic when administered in hot decoction in consequence of the acrid or stimulant principle they contain. Its qualities adapt it to relieve flatulent *colic*. It is also diuretic, and is used in *nephritic complaints*. *L. odoratissima* has an odor resembling that of vanilla, for which reason it is sometimes mixed with smoking tobacco and introduced into cigars. Other species, *L. scariosa* and *L. squarrosa*, are especially high in popular esteem as antidotes to the *rattlesnake's bite*, both internally and locally, and are employed in *gonorrhœa* and also to prepare gargles for *sore throat*. *Liatris* is administered in decoction and tincture.

LIGUSTRUM.—PRIVET.

Troène, Fr.; Rainweide, Hartriegel, G.

Ligustrum vulgare, Linné.

Nat. Ord.—Oleaceæ.

Description.—The privet is a shrub 8 or 10 feet (2.4–3 M.) high, indigenous to Southern Europe; it is cultivated for ornament and in hedges, and is naturalized in the United States. The *leaves* are opposite, elliptic-lanceolate, smooth, thickish, entire on the margin, and about 2 inches (5 Cm.) long; they have a bitterish and astringent taste. The *flowers* are in panicles, the calyx short, the corolla funnel-shaped, four-lobed, white, and of a sweetish agreeable odor. The *berries* are globular-oval, black externally, dark-purple internally, two-celled, and contain two or four ovate-oblong acute seeds.

Constituents.—According to Stenhouse (1854), the leaves contain a principle which yields *quinone*. The bitter principle, *ligustrin*, was not completely isolated by Polex (1839) and Kromayer (1854). It appears to be insoluble in absolute alcohol and ether, and to be allied to *syringin*, the bitter principle of *lilac*, *Syringa vulgaris*, Linné. *Ligustron* is a crystalline, bitter, and fusible principle obtained by Kromayer.

Medical Action and Uses.—The leaves and bark are strongly astringent. They were formerly used to restrain diarrhœa and hæmorrhages, and are still employed in gargles for various forms of *sore mouth* and *throat*.

LIMONIS CORTEX, U. S. Br.—LEMON-PEEL.

Cortex fructus citri, P. G.; *Écorce (Zeste) de citron de limon*, Fr.; *Citronenschale, Limonenschale*, G.

The rind of the recent fruit of *Citrus Limonum*, *Risso* (*C. medica*, var. β , Linné), Steph. and Church, *Med. Bot.*, plate 92; Bentley and Trimen, *Med. Plants*, 54.

Nat. Ord.—Aurantiaceæ.

Origin.—The lemon is a native of the north-western part of India, where it is found in the forests up to an altitude of about 4000 feet (1200 M.). It is extensively cultivated in the basin of the Mediterranean, and the culture has also been introduced into the southern parts of the United States, into Australia, and into most tropical and subtropical countries. Several varieties have been produced from the original stock, of which, besides the lemon, the following are quite distinct:

C. MEDICA, *Risso*, *Citron* or *Cedrat* (Bentley and Trimen, *Med. Plants*, 53). Its flowers are purplish externally; the fruit is 4 to 6 inches (10–15 Cm.) long, ovate-oblong, has a rugged and thick rind, and contains an acid juice.

C. LIMETTA, *Risso*, *Sweet lime*. Its flowers are white; the fruit is smaller than the lemon, oval or roundish, has a smoother and thin rind, and contains an insipidly sweet juice.

C. LUMIA, *Risso*, has likewise a sweet pulp. The *sour lime* is the fruit of *Citrus acida*, *Roxburgh*, *C. acris*, *Miller*, and perhaps other varieties.

The *lemon tree* is 12 to 15 feet (3.5–4.5 M.) high, irregularly branched, and spiny in the leaf-axils; the leaves are oval or ovate-oblong, somewhat serrate, leathery, glossy above, and articulated with the wingless or slightly-winged petiole. The flowers are mostly solitary, have a small calyx, five petals, which are purplish-pink externally, and

numerous stamens. The fruit, 2 to 3 inches (50–75 Mm.) long, varies in shape between oval and obovate, has a nipple-shaped apex, a yellow nearly smooth but glandular pericarp, and is divided into eight to twelve cells, each with two or three seeds.

Description.—Lemon-peel forms either narrow bands or oblong and curved sections; the outer surface has a deep lemon-yellow color, and is somewhat uneven from numerous oil-glands imbedded in the tissue. This portion has an agreeable odor and an aromatic slightly bitter taste; it is the only part which possesses any medicinal value. The white spongy tissue underneath, which is inodorous and nearly tasteless, should be rejected. The Pharmacopœia now directs it to be “in narrow thin bands, with very little of the spongy white inner layer adhering to it.”

Constituents.—The principal constituent is volatile oil. (See OLEUM LIMONIS.) The bitter taste is probably due to hesperidin (see page 289). The white portion is colored black by ferric salts; the principle which gives rise to this color has not yet been isolated.

Off. Prep.—Infus. aurantii comp., Infus. gentianæ comp., *Br.*; Spiritus limonis, *U. S.*; Syrupus limonis, *U. S., Br.*; Tinctura limonis, *Br.*

Medical Uses.—Lemon-peel is used in medicine, as in cookery, for the sake of its flavor.

LIMONIS SUCCUS, *U. S., Br.*—LEMON-JUICE.

Succus citri.—Lime-juice, *E.*; *Suc de citron (de limon)*, *Fr.*; *Citronensaft, Limonensaft*, *G.*

The juice of the fruit of *Citrus Limonum*, *Risso*.

Origin.—(See the preceding article.) The juice is obtained by expressing the ripe fruit.

Description.—Lemon-juice is a slightly turbid, yellowish liquid which has the agreeable odor of lemon and an acid taste. The odor is usually due to the presence of a little volatile oil from the rind, but even without the latter lemon-juice has a slight odor distinct from that of the peel. Stoddard determined its usual specific gravity to be 1.044, and each fluidounce to contain 44 grains of citric acid (about 9¼ per cent. = 42.5 grains in 1 Imperial fluidounce); its acid strength, however, is subject to variation. The *U. S. P.* requires it to contain about 7 per cent. of citric acid, and to have a specific gravity not less than 1.030. According to H. M. Witt (1854), lemon-juice yields from 0.2 to 0.5 per cent. of ash; W. W. Stoddard (1868) obtained between 0.26 and 0.6 per cent. Lemon-juice speedily undergoes decomposition, the citric acid decreasing in quantity, at first slowly, afterward rapidly, as shown by Stoddard. Various methods for its preservation have been suggested, most of which, however, fail to preserve the juice in condition for medicinal use. It has been proposed to concentrate it by evaporation or freezing before bottling it, or to exclude the air by a stratum of fixed oil; the flavor, however, is considerably modified. A better method is to clarify the juice by adding half its volume of strong alcohol; the decanted liquid is then freed from alcohol at a very moderate heat, and the remaining liquid put into suitable bottles, which are heated to near the boiling-point for about an hour, and then hermetically sealed. The juice may be preserved by the same method without the previous treatment with alcohol, but the flavor will be impaired on keeping.

Constituents.—Lemon-juice contains from 7 to 10 per cent. of citric acid and 0.5 to 1 per cent. of gum and sugar. Witt found the principal constituents of the ash to be potassa 44.34, lime 7.61, and phosphoric acid 7.56 per cent. Cossa (1872) obtained 15 per cent. of phosphoric acid.

Off. Prep.—Mistura potassii citratis, *U. S.*; Syrupus limonis, *U. S., Br.*

Medical Uses.—(See ACIDUM CITRICUM.)

LINARIA.—TOAD FLAX.

Herba linariæ.—Snapdragon, *Ramsted*, *Butter-and-eggs*, *E.*; *Linaire commune*, *Fr.*; *Leinkraut, Flachskraut, Löwenmaul*, *G.*

Linaria vulgaris, *Miller*, s. *Antirrhinum Linaria*, *Linné*.

Nat. Ord.—Scrophulariaceæ.

Description.—The toad flax is a European perennial, now extensively naturalized in North America. It is 1 or 1½ feet (30–45 Cm.) high, has alternate, sessile, lance-linear, almost three-nerved, smooth, and light-green leaves, 1 or 1½ inches (25–38 Mm.) long;

and terminal racemes of showy yellow flowers, which have a personate corolla about $\frac{2}{3}$ inch (17 Mm.) long, and at the base continued into a curved spur of the same length. When fresh the herb has a slight disagreeable odor and a bitterish somewhat acrid taste.

Constituents.—The flowers were analyzed by Riegel (1843); they contain a yellow coloring matter, mucilage, sugar, and tannin. Walz obtained an acrid principle, resin, and volatile *linarosmin* and *antirrhinic acid*.

Pharmaceutical Preparation.—**UNGUENTUM LINARIÆ.** 2 parts of the dry plant are macerated with 1 part of alcohol, and then digested with 10 parts of lard until the alcohol has evaporated; the fat is expressed, strained, and stirred until congealed.

Medical Action and Uses.—Common toad flax is used in Germany for *jaundice*, *dropsy*, and *diseases of the skin*, and an ointment is made with it for the cure of *hemorrhoids*. A decoction is prepared with 3ss–5j in water f3vij–f3xvi (Gm. 15–30 in Gm. 250–500).

LINIMENTA.—LINIMENTS.

Embrocations, E., Fr.; *Linimente*, *Einreibungen*, G.

Liniments are liquid or semi-liquid preparations which are intended for external use and are applied to the skin by friction. The vehicle may be oil or alcohol, or sometimes water; many are perfect solutions, others mechanical mixtures which should be well agitated before they are used; a few are of a soft solid consistence at the ordinary temperature, but become liquid when applied to the skin. The U. S. Pharmacopœia now uses cotton-seed oil in place of olive oil, formerly directed.

LINIMENTUM ACONITI, Br.—LINIMENT OF ACONITE.

Liniment d'aconite, Fr.; *Akonitliniment*, G.

Preparation.—Take of Aconite-Root, in No. 40 powder, 20 ounces; Camphor 1 ounce; Rectified Spirit a sufficiency. Moisten the aconite with 20 fluidounces of spirit, and macerate in a closed vessel for 3 days; then transfer to a percolator, and, when the liquor ceases to pass, continue the percolation with more of the spirit, allowing the liquor to drop into a receiver containing the camphor until the product measures 30 fl. oz.—*Br.*

This liniment is one-third weaker than the fluid extract, and differs also in containing camphor. With proper manipulation the aconite-root is practically exhausted by the above process. Procter (1853) had suggested an aconite liniment which was dropped from the present Pharmacopœia, but may be prepared from the fluid extract of aconite-root by mixing 4 fluidounces of it with $\frac{1}{2}$ fluidounce of glycerin and evaporating the mixture to 4 fluidounces.

Medical Uses.—This liniment is convenient for using aconite locally and as an addition to other anodyne applications. It is chiefly employed for the relief of *neuralgia* by saturating with it disks or pledgets of cloth, which are then applied to the painful part. Mixed with an equal quantity of soap liniment, it is said effectually to remove the pain of *dry gangrene*.

LINIMENTUM AMMONIÆ, U. S., Br.—LINIMENT OF AMMONIA.

Linimentum ammoniacum, P. G.; *Linimentum volatile*, *Linimentum ammoniacale*.—*Volatile liniment*, E.; *Liniment ammoniacal (volatil)*, *Savon ammoniacal*, F.; *Flüchtiges Liniment*, *Flüchtige Salbe*, G.

Preparation.—Water of Ammonia 30 parts (130 grains); Cotton-seed oil 70 parts (300 grains); to make 100 parts (430 grains or 1 fluidounce). Mix them.—*U. S.* The proportions by measure are ammonia-water 12 fluidrachms, cotton-seed oil 29 fluidrachms.

Take of solution of ammonia 1 fluidounce; olive oil 3 fluidounces. Mix together with agitation.—*Br.*

The German Pharmacopœia directs 3 parts of olive oil and 1 part of poppy-seed oil, and the French Codex 9 parts of expressed oil of almonds to 1 part of ammonia-water. The fixed oil is partly decomposed, with the formation of an ammonia soap, by means of which the water and oil are kept well mixed, forming an opaque emulsion. Using cotton-

seed oil, the mixture will be liquid at ordinary temperature, and it will be more perfect and less apt to separate if the oil be old, but not rancid, or if mixed with about 10 per cent. of olive oil. The other formulas produce stiffer liniments, which may be kept fluid, as suggested by Rother (1872), by the addition of a little alcohol. On being kept, the liniment becomes thicker, and finally forms a stiff and even granular mass, which Rother prevents by the addition of a minute quantity of oleic acid.

LINIMENTUM AMMONIÆ CAMPHORATUM.—Camphorated volatile liniment, *E.*; Liniment ammoniacal camphré, *Fr.*; Flüchtiges Kampfer-liniment, *G.*—The French Codex and German Pharmacopœia direct it to be made precisely like volatile liniment, except that camphor liniment is substituted for the almond and olive oil.

Medical Uses.—This preparation represents the stimulant rather than the counter-irritant virtues of ammonia. It is used to relieve local pains of a *neuralgic* or *rheumatic* nature, and to palliate both pain and congestion in the forming stage of various inflammations, as *sore throat*, *laryngitis*, *bronchitis*, and *pleurisy*. If prevented from evaporating it may vesicate the skin.

LINIMENTUM BELLADONNÆ, *U. S., Br.*—LINIMENT OF BELLADONNA.

Liniment de belladone, *Fr.*; *Belladonna-Liniment*, *G.*

Preparation.—Fluid Extract of Belladonna 95 parts (437 grains or 1 oz. av.); camphor 5 parts (23 grains); to make 100 parts (460 grains or 1 fluidounce). Dissolve the camphor in the fluid extract.—*U. S.*

Take of belladonna-root, in No. 40 powder, 20 ounces; camphor 1 ounce; rectified spirit a sufficiency. Moisten the belladonna with 20 fluidounces of spirit, and macerate in a closed vessel for 3 days; then transfer to a percolator, and, when the liquor ceases to pass, continue the percolation with more of the spirit, allowing the liquor to drop into a receiver containing the camphor until the product measures 30 fluidounces.—*Br.*

Considering the belladonna-root used in both formulas to be of equal efficiency, the second liniment is one-third weaker.

Medical Uses.—Belladonna liniment is a convenient and efficient preparation for allaying the local pains which belong to *neuralgia*, *rheumatism*, *sprains*, etc. It is advantageously associated with aconite liniment.

LINIMENTUM CALCIS, *U. S., Br.*—LIME LINIMENT.

Liniment of lime, *E.*; *Liniment calcaire*, *Savon calcaire*, *Fr.*; *Kalkliniment*, *G.*

Preparation.—Solution of Lime, Cotton-Seed Oil, each 50 parts (8 oz. av.); to make 100 parts (16 oz. av. or nearly 1 pint). Mix them.—*U. S.*

Take of solution of lime, olive oil, each 2 fluidounces. Mix together, with agitation.—*Br.*

A lime soap is formed by this process, which keeps the excess of the oil emulsified for a short time, the two separating together from the aqueous liquid.

The French Codex directs the separation of the soft saponaceous mass resulting from the agitation of 9 parts of lime-water with 1 part of expressed oil of almonds, and its preservation for use.

Medical Uses.—This liniment is much employed in the treatment of *burns*, both those which are recent and superficial and those which involve the skin, in their ulcerative stage. It is not only a protective, but, as an astringent of a special kind, it hastens the restoration of the injured tissues. It may be used to prevent pitting in confluent *small-pox*. It is applied most efficiently on cloths, which should not be allowed to get dry.

LINIMENTUM CAMPHORÆ, *U. S., Br.*—LINIMENT OF CAMPHOR.

Oleum camphoratum, *P. G.*; *Linimentum camphoratum*.—Camphorated oil, *E.*; *Liniment camphré*, *Huile camphrée*, *Fr.*; *Kampferliniment*, *G.*

Preparation.—Camphor 20 parts (2 oz. av.); Cotton-Seed Oil 80 parts (8 oz. av.); to make 100 parts (10 oz. av.). Dissolve the camphor in the oil.—*U. S.*

Take of camphor 1 ounce; olive oil 4 fluidounces. Dissolve the camphor in the oil.—*Br.* Dissolve camphor 1 part in olive oil 9 parts.—*F. Cod., P. G.*

A simple solution of camphor in oil, which is best obtained by employing the camphor as a fine powder or by digesting the mixture in a closed bottle at a moderate heat.

Souley's *carbolic camphor liniment* is made by dissolving pure carbolic acid 9 parts and camphor 25 parts in absolute alcohol 9 parts and adding olive oil 35 parts.

Off. Prep.—Linimentum chloroformi, Linim. hydrargyri. Linim. terebinth. acet., *Br.*

Medical Uses.—It is used as an anodyne and discutient for *sprains, bruises, and glandular swellings* and for the relief of *rheumatic pains*. It is also serviceable in preventing the ill effects of pressure by surgical apparatus and by decubitus.

LINIMENTUM CAMPHORÆ COMPOSITUM, *Br.*—COMPOUND LINIMENT OF CAMPHOR.

Liniment ammoniacal camphré anglais, Fr.; Ammoniak- und Kampher-Liniment, G.

Preparation.—Take of Camphor 2½ ounces; Oil of Lavender 1 fluidrachm; Strong Solution of Ammonia 5 fluidounces; Rectified Spirit 15 fluidounces. Dissolve the camphor and oil of lavender in the spirit; then add the solution of ammonia gradually, shaking them together until a clear solution is formed.—*Br.*

Medical Uses.—The characteristic of this preparation, as distinguished from simple liniment of camphor, is that it is rendered stimulant, and even rubefacient, by the strong water of ammonia it contains. It is a convenient liniment in cases of local *rheumatic, neuralgic, and traumatic pains*.

LINIMENTUM CANTHARIDIS, *U. S.*—LINIMENT OF CANTHARIDES.

Huile de cantharides térébenthinée, Fr.; Spanischfliegen-Liniment, G.

Preparation.—Cantharides, in No. 60 powder, 15 parts (1½ oz. av.); Oil of Turpentine a sufficient quantity; to make 100 parts (10 oz. av.). Digest the cantharides with 100 parts (10 oz. av.) of oil of turpentine in a close vessel by means of a water-bath for 3 hours; then strain and add enough oil of turpentine through the strainer to make the liniment weigh 100 parts (10 oz. av. or about 11 fluidounces).—*U. S.*

Cantharidin is soluble in oil of turpentine; the digestion may be effected in a bottle partly closed by a stopper. (See also LIQUOR EPISPASTICUS.)

OLEUM CANTHARIDATUM, *P. G.*, is made by digesting for 10 hours coarsely-powdered cantharides 3 parts in rape-seed oil 10 parts. The filtered oil is of a green-yellow color.

Medical Uses.—This is a very powerful stimulant and counter-irritant preparation. Its advantages over turpentine liniment on the one hand and over blisters upon the other are not apparent, and unless carefully used it may occasion troublesome irritation, and even ulcers, where it is applied, and may be conveyed by the patient's fingers to the eyes, genitals, etc.

LINIMENTUM CHLOROFORMI, *U. S., Br.*—LINIMENT OF CHLOROFORM.

Liniment au chloroforme, Fr.; Chloroform-Liniment, G.

Preparation.—Commercial Chloroform 40 parts (2 oz. av.); Soap Liniment 60 parts (3 oz. av.); to make 100 parts (5 oz. av. or nearly 4 fluidounces). Mix them.—*U. S.*

Take of chloroform, liniment of camphor, each 2 fluidounces. Mix.—*Br.*

Chloroform 1 part, expressed oil of almond 9 parts.—*F. Cod.* The preparation bearing the same name in the three pharmacopœias differs essentially in composition as well as in the proportion of chloroform.

Medical Uses.—The purpose of this preparation was probably to prolong, and at the same time mitigate, the local anæsthetic action of chloroform. But the object is better accomplished by a mixture of chloroform and soap liniment, to which tincture of aconite-root may be added.

LINIMENTUM CROTONIS, *Br.*—LINIMENT OF CROTON OIL.

Liniment crotoné, Fr.; Krotönöl-Liniment, G.

Preparation.—Take of Croton Oil 1 fluidounce; Oil of Cajeput, Rectified Spirit, each 3½ fluidounces. Mix.—*Br.*

This is simply a solution of croton oil in alcohol and oil of cajeput, and has the odor of the latter.

Medical Uses.—There is an apparent incongruity in associating a prompt but tran-

sient irritant, like oil of cajeput, with one whose operation is slow and is scarcely active until the characteristic croton pustulation is produced. Possibly, the rubefaction of the skin by the one oil was intended to hasten the more permanent action of the other. But the preparation has little to recommend it before an extemporaneous solution of croton oil in olive oil, with or without the addition of oil of cajeput, cloves, or cassia.

LINIMENTUM HYDRARGYRI, *Br.*—LINIMENT OF MERCURY.

Linimentum mercuriale.—*Liniment mercuriel*, Fr.; *Quecksilber-Liniment*, G.

Preparation.—Take of Ointment of Mercury 1 ounce; Solution of Ammonia, Liniment of Camphor, each 1 fluidounce. Liquefy the ointment of mercury in the liniment of camphor with a gentle heat; then add the solution of ammonia gradually, and mix with agitation.—*Br.*

This may be prepared in a wide-mouthed vial if the ointment and liniment are digested together and frequently agitated until the lumps have disappeared, when the ammonia-water should be added and well incorporated by shaking. The liniment has a gray color from the finely-divided mercury.

Medical Uses.—The camphor and ammonia in this preparation are intended by their stimulant action to promote the discutient and absorbent action of the mercury. As it must be applied with friction, there is great danger of its causing salivation. It is less efficient in promoting the resolution of enlarged and indurated glands, etc. than are mercurial ointments and plasters, especially those containing the iodides of mercury.

LINIMENTUM IODI, *Br.*—LINIMENT OF IODINE.

Liniment ioduré, Fr.; *Jodliniment*, G.

Preparation.—Take of Iodine $1\frac{1}{4}$ ounces; Iodide of Potassium $\frac{1}{2}$ ounce; Glycerin $\frac{1}{2}$ ounce; Rectified Spirit 10 fluidounces. Dissolve the iodine, iodide of potassium, and glycerin in the spirit.—*Br.*

This is much stronger than the *Tinctura iodi*, from which it also differs in containing about $2\frac{1}{2}$ per cent. of glycerin. The potassium iodide adapts the liniment for use with a small quantity of aqueous liquids by preventing the precipitation of the iodine.

Medical Uses.—As it is probable that a very minute proportion, if any, either of iodine or of iodide of potassium is absorbed by the sound skin, it must be concluded that this liniment will be less efficient as a local application than either the simple or compound iodine ointment, in both of which the active ingredients are kept longer in contact with the integument than they can be in a liniment.

LINIMENTUM OPII, *Br.*—LINIMENT OF OPIUM.

Anodyne liniment, E.; *Liniment opiacé*, Fr.; *Opiumliniment*, G.

Preparation.—Take of Tincture of Opium, Liniment of Soap, each 2 fluidounces. Mix.—*Br.*

The *liniment savonneux opiacé* of the French Codex was made by triturating 5 parts of powdered soap with 90 parts of expressed oil of almonds, and adding 5 parts of tincture of opium; it must be well agitated.

Medical Uses.—Being merely a mixture of laudanum and soap liniment, its fixed proportions are rather embarrassing than convenient. The quantity of laudanum used should vary with the condition of the affected part as to delicacy, the degree of pain, etc.

LINIMENTUM PLUMBI SUBACETATIS, *U. S.*—LINIMENT OF SUB-ACETATE OF LEAD.

Liniment saturné, *Beurre de saturne*, *Baume universelle*, Fr.; *Bleil liniment*, G.

Preparation.—Solution of Subacetate of Lead 40 parts (2 oz. av.); Cotton-Seed Oil 60 parts (3 oz. av.); to make 100 parts (5 oz. av. or nearly $4\frac{3}{4}$ fluidounces). Mix them.—*U. S.*

This yields a yellowish-white opaque emulsion which does not separate on standing, but gradually stiffens. It is made extemporaneously by weighing the materials into a vial and then agitating well.

Medical Uses.—A convenient discutient liniment for sprains, bruises, chilblains, inflamed glands, and chapped hands.

LINIMENTUM POTASSII IODIDI CUM SAPONE, *Br.*—LINIMENT OF IODIDE OF POTASSIUM AND SOAP.

Liniment savonneux ioduré, Fr.; Jodkalium-Seifenliniment, G.

Preparation.—Take of Curd Soap, cut small, 2 ounces (16 parts); Iodide of Potassium $1\frac{1}{2}$ ounces (12 parts); Glycerin 1 fluidounce (8 fluid parts); Oil of Lemon 1 fluidrachm (1 fluid part); Distilled Water 10 fluidounces (80 fluid parts). Reduce the soap to fine shreds, and mix this with the water and glycerin in a porcelain dish over the water-bath. When the soap is dissolved pour the liquid into a mortar in which the iodide of potassium has previously been powdered. Mix briskly, and continue the trituration until the mixture is cold. Set aside for an hour; then rub well the oil of lemon into the cream-like product.—*Br.*

Medical Uses.—This liniment is even more objectionable than liniment of iodine, since it contains only the iodine salt, and no iodine, as the latter preparation does. The clinical evidence of any real benefit being derived from it through its iodide of potassium has never been furnished. If cutaneous absorption of the iodide of potassium be desired, it will be secured much more readily by the prolonged application of compresses saturated with a strong solution of the iodide and their protection by a water-proof covering.

LINIMENTUM SAPONIS, *U. S., Br.*—SOAP LINIMENT.

Linimentum saponato-camphoratum liquidum, P. G.—*Spiritus nervinus camphoratus; Liquid opodeldoo, E.; Liniment savonneux camphré, Fr.; Flüssiger Opodeldok, G.*

Preparation.—Soap, in shavings, 10 parts (8 oz. av.); Camphor 5 parts (4 oz. av.); Oil of Rosemary 1 part (350 grains or 7 fluidrachms); Alcohol 70 parts (56 oz. av. or 4 pints and $1\frac{1}{2}$ fluidounces); Water a sufficient quantity; to make 100 parts (80 oz. av.). Digest the soap in 14 parts ($11\frac{1}{2}$ oz. av. or $10\frac{3}{4}$ fluidounces) of water until it is dissolved; dissolve the camphor and oil in the alcohol; mix the solutions and filter through paper, adding enough water, through the filter, to make the liniment weigh 100 parts (80 oz. av. or about 5 pints).—*U. S.*

Take of hard soap, in fine shavings, 2 ounces; camphor 1 ounce; oil of rosemary 3 fluidrachms; rectified spirit 16 fluidounces; distilled water 4 fluidounces. Mix the water with the spirit, and add the oil of rosemary, the soap, and the camphor. Macerate for 7 days at a temperature not exceeding 70° F., with occasional agitation, and filter.—*Br.*

Both Pharmacopœias use soap made with olive oil and soda, which is more soluble in the alcohol than soap made with animal fat, but both omit to state whether or not the soap is to be dried before being weighed. The details of the first process are rapidly executed: the soap on being digested with the water in a tared vessel yields a thick and smooth almost jelly-like solution, to which sufficient hot water should be added to compensate for the loss by evaporation; the alcoholic solution of the oil and camphor is then added, the mixture rapidly stirred, and the vessel well closed and allowed to cool. If white Castile soap is used the liniment will have a pale-yellowish color, and is at once ready for use, but if mottled soap is employed the preparation will be turbid, and should be filtered, when it will have a brownish color, due to the iron held in solution. With the slight reduction in the amount of soap, as compared with the process of 1870, the preparation is less liable to have a portion of the soap deposited in cold weather than formerly. Barekhausen (1872) suggested the use of a potassa soap made of rape-seed oil, which has the advantage of not separating from the alcohol even at the freezing temperature; and a soap made from castor oil has been suggested by C. H. Clark and L. E. Sayre in 1872. To accomplish the same result, the German Pharmacopœia uses a potassa soap of olive oil.

Allied Preparations.—LINIMENTUM SAPONATO-CAMPHORATUM, *S.* BALSAMUM OPODELDOC.—Opodeldoo, Steer's opodeldoo, *E.*: Baume opodeldooch, Baume de savon, *Fr.*: Opodeldok, *G.*—Digest, in a suitable vessel, of tallow soap 30 parts, camphor 24 parts, and 90 per cent. alcohol 250 parts; when dissolved add oil of thyme 2 parts, oil of rosemary 6 parts; agitate with 10 parts of animal charcoal, add ammonia-water 10 parts; filter rapidly by means of a well-covered funnel, collect the filtrate in suitable wide-mouthed vials, and allow it to congeal.—*F. Cod.*

The German Pharmacopœia uses soap 6 parts, camphor 2 parts, alcohol 81 parts, and glycerin 5 parts: the warm solution is filtered; then it adds oil of thyme 0.4 part, oil of rosemary 0.6 part, and ammonia-water 5 parts. The liniment is solid at the ordinary temperature, but readily liquefies at the temperature of the body, and is white or yellowish, opalescent, and somewhat translucent.

LINIMENTUM SAPONATO-AMMONIATUM. Dissolve 1 part of Castile soap in 30 parts of water and 10 parts of alcohol, and add 15 parts of ammonia-water.—*P. G.* 1872.

SPIRITUS SAPONATUS, P. G.—Tincture of soap, *E.*; Teinture de savon, *Fr.*; Seifenspiritus, *G.*—Digest olive oil 6 parts, solution of potassa (sp. gr. 1.144) 7 parts, and alcohol 7 parts until saponified; add alcohol to replace that which may have evaporated; afterward add alcohol 23 parts and water 17 parts.—*P. G.* It is a yellowish liquid of an alkaline reaction.

SAPONIMENTUM is an alcoholic solution of neutral soap, combined with other medicaments.

Medical Uses.—An anodyne and discutient preparation, used for the same purposes as camphor liniment, but more efficient, because more stimulant, than that preparation. The *opodehloc balsam* (*P. G.*), again, is more stimulant than the official preparation.

LINIMENTUM SINAPIS COMPOSITUM, U. S., Br.—COMPOUND LINIMENT OF MUSTARD.

Liniment sinapisé composé, Fr.; *Zusammengesetztes Senfliniment, G.*

Preparation.—Volatile Oil of Mustard, 3 parts (24 grains); Extract of Mezereum 2 parts (16 grains); Camphor 6 parts (48 grains); Castor Oil 15 parts (120 grains); Alcohol a sufficient quantity; to make 100 parts (800 grains). Dissolve the extract of mezereum and the camphor in 70 parts (560 grains or 1½ fluidounces) of alcohol; then add the oil of mustard and castor oil, and finally enough alcohol to make the product weigh 100 parts (800 grains or about 2 fluidounces).—*U. S.*

Take of oil of mustard 1 fluidrachm; ethereal extract of mezereum 40 grains; camphor 120 grains; castor oil 5 fluidrachms; rectified spirit 4 fluidounces. Dissolve the extract of mezereum and camphor in the spirit, and add the oil of mustard and castor oil.—*Br.*

The solution is readily effected on maceration in a vial. The second formula yields a somewhat stronger preparation.

Medical Uses.—It was doubtless intended in this compound to provide a powerful counter-irritant and revulsive, and it is described as a useful embrocation. We should hesitate to employ it without feeling more assured than at present of its being safe. The sores made by mezereum or by mustard are very intractable. Moreover, if the oil of mustard is in such proportion as to produce its proper effect, it will do so long before the mezereum has begun to act. Hence one or the other ingredient of the liniment would seem to be superfluous.

LINIMENTUM TEREBINTHINÆ, U. S., Br.—LINIMENT OF TURPENTINE.

Linimentum terebinthinatum, P. G.—*Liniment térébenthiné, Fr.*; *Terpentinliniment, G.*

Preparation.—Resin Cerate 65 parts (13 oz. av.); Oil of Turpentine 35 parts (7 oz. av. or 7¼ fluidounces); to make 100 parts (20 oz. av.). Add the oil to the cerate, previously melted, and mix them thoroughly.—*U. S.*

Take of soft soap 2 ounces; camphor 1 ounce; oil of turpentine 16 fluidounces. Dissolve the camphor in the oil of turpentine; mix the soap with 2 fluidounces of water; then rub these fluids together until they are thoroughly mixed.—*Br.*

Oleol of chamomile, oil of turpentine, equal parts.—*F. Cod.* Potassium carbonate 6 parts, green soap 54 parts, oil of turpentine 40 parts.—*P. G.*

The first formula yields what is known as *Kentish liniment*; the cerate should be melted at a low heat, and then the oil gradually added, with continued stirring. The second process is a considerable modification of the former, and requires continued trituration of the soap in a mortar, with the gradual addition of the oil, in order to obtain a uniform mass. The liniments of the French and German Pharmacopœias differ from each other and from the foregoing.

Medical Uses.—This preparation was originally employed in the treatment of *burns* and *scalds*, which it protects from the irritating influence of the air, while it maintains a moderate stimulation which tends to prevent the ulterior effects of those injuries in which the vitality of the tissues is more or less impaired. It is essential for its successful use that the primary dressing should not be removed for 24 hours, and that the liniment should not be continued longer than is necessary to establish a healthy action in the part. This preparation is also serviceable in superficial *erysipelas* or *erythema* arising from traumatic causes, and in *frost-bite* without active inflammatory phenomena.

LINIMENTUM TEREBINTHINÆ ACETICUM, Br.—LINIMENT OF TURPENTINE AND ACETIC ACID.

Liniment térébenthiné acétique, Fr.; Terpenthin- und Essig-Liniment, G.

Preparation.—Take of Oil of Turpentine 4 fluidounces (4 fluid parts); Glacial Acetic Acid 1 ounce (1 part); Liniment of Camphor 4 fluidounces (4 fluid parts). Mix.—*Br.*

Medical Uses.—This preparation is essentially “St. John Long’s liniment,” which name it derived from a quack who professed to cure almost every painful local disease by its application. It is particularly efficient in *neuralgia* when applied over the points of exit of the trunks or the terminal distribution of the affected nerves. It should then be employed so as to vesicate the part superficially and over a small area. It may also be applied to relieve other local pains and inflammations, such as limited *muscular rheumatism*, and to the epigastrium to allay *vomiting* depending on inflammation of the stomach.

LINTEUM.—LINT.

Linteum carptum.—*Charpie, Fr., G.*

Preparation and Description.—Lint was originally made from bleached linen cloth by scraping it until it became soft and woolly. At the present time it is almost exclusively prepared by means of machinery from a fabric woven for this purpose, and is known as *patent lint* in distinction to the hand-made lint. It is in rather thick but very soft and fleecy sheets, and when viewed under the microscope shows the bast-cells of flax as long cylindrical tubes, which are slightly thickened in a few places and somewhat pointed toward both ends. The cell-walls are very thick by concentric deposits, leaving only a small central cavity. Immersed in an ammoniacal solution of copper, they swell considerably, and are ultimately dissolved without leaving any residue. These cells resemble the bast-fibres of hemp, but the latter are thinner, blunt at the ends, with a still smaller cavity in the centre, and adhere more firmly together, hence the coarser appearance of hemp fabrics.

Cotton is now often more or less substituted for linen, and lint made in this way is known as *cotton lint*. The fibre of cotton is described on page 744, and may be readily distinguished from linen fibre by the microscope.

Tests for Linen and Cotton.—Boiled with a concentrated solution of potassa, the linen fibre turns bright yellow within 2 minutes, while cotton fibre remains white or becomes pale-yellowish. Dipped in a solution of *rosolic acid*, which is known in commerce as *aurin* or yellow corallin, and afterward in a concentrated solution of sodium carbonate, linen fibre is dyed rose-red, while cotton fibre remains white. When immersed in a tincture of *madder*, linen fibre acquires a yellowish-red, but cotton fibre a light-yellow, color. Cold concentrated *sulphuric acid* does not materially alter linen fibre within 1 or 2 minutes, while cotton fibre is destroyed in the same time. When rubbed with a *fixed oil*, linen fabric remains white and opaque, but cotton becomes translucent.

Surgical Action and Uses.—The purpose of lint is to provide a soft and unirritating covering for *wounds*; to protect them from the air and the foreign particles floating in it; to moderate and graduate the pressure of bandages and other surgical apparatus; to absorb the more liquid discharges; and to be introduced into wounds which are not intended to heal immediately. Of the different forms of lint, that which is made of old linen by picking apart its threads is the most elastic and absorbent, and by far the most comfortable to the patient; that which is made by scraping old linen is very suitable for small wounds and abrasions; and the so-called patent lint is the least eligible unless its threads are unravelled so as to form a soft mass. But the last-mentioned lint, when made of cotton, as it usually is, does not absorb discharges nearly as well as that derived from linen, chiefly on account of the oil which adheres to it. Of late years cotton lint has been prepared entirely free from oil, and therefore possessing a greater absorbent power, and is at the same time impregnated with carbolic acid, so as to render it disinfectant. But a defect of all cotton lint is, that as soon as it becomes saturated with liquids it entirely loses its elasticity, which is not the case with old linen lint or charpie. A substance analogous to charpie is oakum, which consists of tarred ropes picked into shreds. Its value, derived from the tar impregnating it and the greater looseness of its texture, is counterbalanced by the harshness of the material. It was first suggested by Surgeon Ruschenberger, U. S. N., in 1862.

LINUM, U. S.—FLAXSEED.

Lini semina, Br.; *Semen Lini*, P. G.—*Linseed*, E.; *Semence (Graine) de lin*, Fr.; *Leinsamen*, *Flachssamen*, G.

The seed of *Linum usitatissimum*, Linné. Woodv., *Med. Bot.*, plate 3; Bentley and Trimen, *Med. Plants*, 39.

Nat. Ord.—Linacææ.

LINI FARINA, Br.—FLAXSEED MEAL.

Linseed meal, E.; *Farine de lin*, Fr.; *Leinsamenmehl*, *Leinmehl*, G.

Origin.—Flax is probably indigenous to the Mediterranean basin, but has been cultivated for so long a period, and grows so spontaneously wherever it has been introduced, that it is difficult to determine its native country. It has an annual stem about 2 feet (60 Cm.) high, alternate linear-lanceolate leaves, and terminal flowers with five ovate, pointed, and three-nerved sepals and five fugacious blue-veined and short-clawed petals. The fruit is an ovate five-celled and ten-seeded capsule, each cell being again imperfectly divided. As cultivated in the various tropical and temperate countries, several varieties have been observed, differing in the shape and size of the seeds and more markedly in other characters. The seeds are principally imported from Russia and Germany. (See OLEUM LINI.)

Description.—Flaxseed is $\frac{1}{8}$ to $\frac{1}{4}$ inch (4–6 Mm.) long, oblong-ovate, considerably flattened, but the sides convex and the edges obtuse, rounded below and oblique at the apex, beneath which the hilum is located in a slight depression. The testa is of a yellowish-brown color, glossy, and covered with a transparent epithelium, which swells very considerably in water; the kernel consists of a very thin endosperm and two large plano-convex oily greenish or yellowish cotyledons having the shape of the seed, with the radicle projecting into the pointed end. The brown coloring matter is contained in the inner cell-row of the testa; the albumen and cotyledons are composed of thin-walled parenchyma, the cells being filled with proteids and oil, but are free from starch. The seed is inodorous, and has a mucilaginous, bitterish, and oily taste.

PLACENTÆ SEMINIS LINI, P. G., are the press-cakes obtained in preparing linseed oil, and on grinding yield the so-called *cake meal*. These press-cakes are of a dingy-gray color, and their powder shows under the microscope fragments of the brown-yellow testa of linseed, but none of the blackish-brown testa of rape-seed, and yields with boiling water and on filtering a mucilaginous liquid, which when cold is not colored blue by iodine. But cake meal is not recognized by the U. S. Pharmacopœia, which requires that "ground flaxseed, for medicinal purposes, should be recently prepared, free from unpleasant or rancid odor, and, when extracted with disulphide of carbon, should yield not less than 25 per cent. of fixed oil." The Br. P. and F. Cod. likewise order the ground seeds.

Constituents.—The most important constituents of flaxseed are the *mucilage* and *fixed oil*, the latter (see OLEUM LINI), according to Chevallier (1844), being contained in the embryo to the extent of about 30 to 39 per cent., the former in the epithelium to the extent of about 15 per cent. The mucilage is $C_{12}H_{20}O_{10}$, and by nitric acid is converted into mucic acid. Besides the above, Leo Meyer (1826) found protein compounds, a small portion of wax, resin, sugar, malates, acetates, and other salts, which are dissolved with the mucilage. The ash amounts to about 3 per cent., and consists of phosphates, with some sulphates and chlorides of potassium, calcium, and magnesium.

Off. Prep.—1. Of flaxseed: *Farina lini*, *Infus. lini*, Br. 2. Of flaxseed meal: all cataplasms, except *Catapl. fermenti*, Br.

Medical Action and Uses.—The union of oil and mucilage in flaxseed adapts it for external application in the many cases in which an emollient is required, and the ready absorption of at least the water in its infusion has led to its internal use as a diluent and diuretic. Flaxseed tea is universally employed in *inflammations* of the mucous membranes of the *respiratory*, *digestive*, and *urinary* organs. It serves as the basis of numerous ptisans, and is injected into the rectum, vagina, and bladder in irritations of those organs. It forms an ordinary drink in *renal* and *vesical* irritations. The tea is made with $\frac{1}{2}$

FIG. 174.

ounce of flaxseed to a pint of boiling water, macerated for 2 hours and strained. It may be taken in any convenient quantity. The compound infusion (U. S. P. 1870) contains liquorice, which adapts it to bronchial affections. Flaxseed mucilage is prepared by boiling the seed. It is commonly used to cover *erysipelatos* and other inflammations of the skin, *burns*, etc., but is objectionable if allowed to get dry, by rendering the skin stiff; it is also apt to become sour and irritating. For the purposes last mentioned acetate of lead is sometimes dissolved in it. It precipitates the solution of subacetate of lead.

The flaxseed poultice is prepared by gradually pouring boiling water upon flaxseed meal and stirring the mixture until it acquires the proper consistence. As it tends to render the skin white, wrinkled, and sodden, and to excite a pustular eruption, the part to which it is applied should first be covered with sweet oil, fresh lard, or glycerin; or, as directed officinally (British Pharmacopœia), olive oil should be mixed with the meal of which the poultice is made. Wherever applied, it should be kept in close contact with the skin. It may be medicated by the addition of narcotic tinctures or watery solutions, of astringents, stimulants, etc.

LIQUIDAMBAR.—SWEET GUM.

A balsamic exudation from *Liquidambar styraciflua*, *Linne*.

Nat. Ord.—Hamamelaceæ, Balsamifluæ.

Origin.—The sweet gum tree, also called *bilsted* and *copalm*, is a handsome North American tree, from 40 to 60 feet (12–18 M.) high, growing from Connecticut and Illinois southward to Florida and westward to Mexico. It has a reddish, fine-grained, and compact wood and a thick gray deeply-furrowed astringent bark, that of the branches being usually furnished with thick wing-like ridges of cork. The leaves are dark-green, round in outline, palmately five to seven-lobed, and the lobes serrate. The fruit is capsular, beaked, aggregated in globular heads, together with the indurated scales. The leaves, fruit, and bark when bruised have an agreeable odor; the taste of the bark is balsamic and astringent, and that of the other parts mentioned aromatic and acidulous. In its southern locations the tree yields a balsamic exudation from incisions made in the bark.

Description.—Sweet gum, also called *gum wax*, exudes in the form of a thick liquid having the density of syrup and a yellowish color. On standing it thickens, becomes darker in color, and finally hard at the ordinary temperature, and breaks with a resinous fracture, which is of a variegated appearance, the color being brown, with lighter (and even white) spots and streaks. It softens somewhat by the warmth of the hand, and when heated fuses to a yellowish-brown liquid. It has a very pleasant balsamic odor and taste, the latter being followed by pungency. It dissolves completely, fragments of bark excepted, in alcohol, ether, and chloroform, the alcoholic solution having a slight acid reaction.

Constituents.—A pretty complete analysis of sweet gum was made by William L. Harrison (1874). He obtained, by distillation with a solution of sodium carbonate in water, 3½ per cent. of an aromatic oily hydrocarbon, having the properties of *styröl*, but which was found by Flückiger to be not converted into metastyröl; the aqueous liquor in the retort, on being supersaturated with acid, yielded 5½ per cent. of *cinnamic acid*. The portion insoluble in the alkaline liquor was partly dissolved in hot petroleum benzin, the solution yielding *styracin* on cooling, and finally left a dark-brown nearly tasteless and inodorous resin. The sweet gum examined contained 9 per cent. of impurities. On treating sweet gum with warm petroleum benzin, cinnamic acid and styracin are taken up, and crystallize together on cooling; they may then be separated with weak ammonia, which dissolves the cinnamic acid only. Harrison observed also that by heating sweet gum with a small quantity of water and stirring frequently a gray-colored mixture is obtained resembling storax. The presence of cinnamic acid in sweet gum was previously proved by Hanbury (1857) and Procter (1866). It will be observed that sweet gum agrees in composition with storax, which in addition contains water mechanically mixed with it.

Pharmaceutical Uses.—A *syrup of sweet gum* is made by the official process for syrup of tolu, and is much employed in some parts of the Southern States. A *syrup of sweet-gum bark* is likewise used and prepared by the official process for syrup of wild cherry (Dr. C. W. Wright, 1856). According to L. Hughes (1876), an ethereal solution of sweet gum is very serviceable for extinguishing the mercury in preparing mercurial ointment.

Medical Action and Uses.—These appear to be identical with those of storax;

and indeed the latter is defined by the United States Pharmacopœia to be "a balsam prepared from the inner bark of *Liquidambar orientalis*." Its action is that of an aromatic resin, operating particularly upon the respiratory and urinary mucous membranes. It is employed in the treatment of chronic profluvia of these parts, such as *bronchitis*, *cystitis*, *pyelitis*, and *glect*. Externally, it was used formerly in an ointment for the treatment of *scabies* (as storax now is), and for various purposes to which resin cerate is applied, including *frost-bite*, indolent *ulcers*, and *burns*. A decoction, and also a syrup prepared from the bark, are said to be used in the Western and Southern States in the treatment of infantile *diarrhœa* and *dysentery*. The former is sometimes made with milk. The bark, like the leaves, is astringent.

LIQUORES.—SOLUTIONS.

Solutés, Fr.; *Lösungen*, G.

With the exception of infusions, decoctions, and syrups, and of those aqueous liquids containing volatile oils or gases, all aqueous solutions are, by the U. S. Pharmacopœia, designated *Liquores*; the British and some other pharmacopœias embrace under the same head also aqueous solutions of gases. The German Pharmacopœia is inconsistent in its designation, lime-water, chlorine-water, and lead-water being placed among *Aquæ*, while ammonia-water is regarded as a *liquor*. Gutta-percha solution and blistering liquid alone have a menstruum other than water.

LIQUOR ACIDI ARSENIOSI, U. S.—SOLUTION OF ARSENIOUS ACID.

Liquor arsenici chloridi, U. S. 1870.—*Liquor arsenici hydrochloricus*, Br.—*Solution of chloride of arsenic*, *Hydrochloric solution of arsenic*, E.; *Liqueur arsénicale hydrochlorique*, Fr.; *Chlorarsenik-Lösung*, G.

Preparation.—Arsenious Acid, in small pieces, 1 part (20 grains); Hydrochloric Acid 2 parts (40 grains); Distilled Water a sufficient quantity; to make 100 parts (2000 grains). Boil the arsenious acid with the hydrochloric acid, and with 25 parts (500 grains or 9 fluidrachms) of distilled water, until solution has been effected. Filter the liquid, and pass enough distilled water through the filter to make the solution weigh 100 parts (2000 grains, measuring 35 fluidrachms).—U. S.

Arsenious acid in powder 87 grains; hydrochloric acid 2 fluidrachms; distilled water sufficient to make 1 pint (Imperial).—Br.

Arsenious and hydrochloric acids, when heated together, and then distilled, unite to form volatile *arsenious chloride*, As_2Cl_6 , which, on being dissolved in water, is decomposed again into the compounds from which it was prepared. The official solutions, therefore, contain simply the two acids.

Properties.—The solution is colorless, has an acid reaction, and an acidulous taste. Sulphuretted hydrogen yields at once a bright-yellow precipitate of sulphide of arsenic. In arsenic strength it corresponds with Fowler's solution, containing 1 per cent. of arsenious acid, or 4.57 grains (4 grains, U. S. 1870) to the fluidounce, or 4.35 grains (4 grains, Br. 1867) to the Imperial fluidounce; Valangin's solution contained 0.38 per cent. of arsenious acid, or $1\frac{1}{4}$ grains to the fluidounce. The pharmacopœial solutions have the specific gravity 1.009 U. S., 1.010 Br.

The strength is determined as follows: "If 25 Gm. of solution of arsenious acid be boiled for a few minutes with 2 Gm. of bicarbonate of sodium, the resulting liquid should not decolorize less than 48.5 Cem. of the volumetric solution of iodine (corresponding to 1 per cent. of arsenious acid of the required purity)."—U. S. "442 grains boiled for 5 minutes with 20 grains of bicarbonate of sodium, and then diluted with 6 fluidounces of distilled water, to which a little mucilage of starch has been added, does not give with the volumetric solution of iodine a permanent blue color until 875 grain-measures have been added."—Br.

Allied Preparation.—LIQUOR ARSENICI BROMIDI. Clemens's formula (1876), somewhat modified in the manipulation, is as follows: Mix 1 part each of powdered arsenious acid and pure carbonate of potassium, and dissolve in about 10 parts of boiling water; then add 80 parts of water and 2 parts of bromine, set aside at a moderate temperature until the liquid has become colorless, and add sufficient water to make the solution weigh 100 parts. It is said to improve by age. Bromide of arsenic, AsBr_3 , is crystalline, melts near 25°C . (77°F .), boils and volatil-

izes without decomposition near 220° C. (428° F.), and is decomposed by water, with the formation of arsenious and hydrobromic acids. The above solution probably contains bromide and arsenate of potassium.

Medical Uses.—The advantages of this preparation, which contains the same proportion of arsenic as Fowler's solution, are far from being apparent. Indeed, its action has been pronounced very uncertain. It may be given in *doses* of from 3 to 5 drops, largely diluted and after meals.

LIQUOR AMMONII ACETATIS, U. S., Br.—SOLUTION OF ACETATE OF AMMONIUM.

Liquor ammoniæ acetatis, Liquor ammonii acetici, P. G.; *Acetas ammonicus liquidus, Spiritus Mindereri*.—*Spirit of Mindererus*, E.; *Acetate d'ammoniaque liquide, Esprit de Mindererus*, Fr.; *Ammoniumacetal-Lösung, Essigsäure Ammonium-Lösung*, G.

Preparation.—Diluted Acetic Acid 100 parts (weight or measure prescribed): Carbonate of Ammonium 10 parts (weight or measure prescribed). Add a sufficient quantity of carbonate of ammonium gradually to the diluted acetic acid until the latter is neutralized. This preparation should be freshly made when required for use.

Solution of acetate of ammonium may also be prepared in the following manner: Carbonate of ammonium 10 parts (2½ oz. av.); acetic acid 28 parts (7 oz. av.); distilled water 142 parts (35½ oz. av.). Dissolve the carbonate of ammonium in 80 parts (20 oz. av. or 19½ fluidounces) of distilled water, and filter the solution. To the acetic acid add 62 parts (15½ oz. av. or 14½ fluidounces) of distilled water. Keep the solutions in separate, well-stopped bottles, and when solution of acetate of ammonium is to be dispensed weigh equal quantities of each solution and mix them.—U. S.

Strong solution of ammonium acetate 4 fl. oz., distilled water sufficient for 20 fluidounces.—Br. Spec. grav. 1.022.

LIQUOR AMMONII ACETATIS FORTIOR.—Add crushed carbonate of ammonium 17½ oz. gradually to 45 oz. of acetic acid; then add more of the acid (about 5 oz.) until a neutral liquid results, and add sufficient water to yield 60 fluidounces of product. Preserve in bottles free from lead.—Br. Spec. grav. 1.073.

The directions of the U. S. Pharmacopœia indicate that the solution is to contain some carbonic acid. The first formula directs the *neutralization* of the acetic acid, which, however, cannot be ascertained by litmus-paper, owing to the carbonic acid remaining in solution. Turmeric-paper is preferable, in so far as it more readily indicates even a slight excess of ammonium carbonate by the brown color produced; but the exact point of neutralization cannot be ascertained. Under the circumstances the taste is as reliable as test-paper. After the pricking sensation upon the tongue caused by the carbonic acid has disappeared the taste should be saline and free from alkalinity. This result is accomplished by the second process, provided that translucent ammonium carbonate is used in making one of the solutions. The correct weights of the alkaline and acid solutions having been taken, they are mixed in a graduate, and after the violent effervescence has subsided the liquid is poured into the vial. For the *extemporaneous* preparation by this process of 4 fluidounces of this solution, dissolve 110 grains of ammonium carbonate in 880 grains (or 15½ fluidrachms) of distilled water; mix 308 grains (or 5 fluidrachms and 10 minims) of acetic acid with 682 grains (or 12 fluidrachms) of distilled water, and add the acid liquid to the first solution. After effervescence has ceased the liquid will measure about 33 fluidrachms.

Properties.—It is "a clear, colorless liquid, free from empyreuma, of a mildly saline taste and a neutral or slightly acid reaction; sp. gr. 1.022. It is wholly volatilized by heat. When heated with potassa it evolves vapors of ammonia, and when heated with sulphuric acid it gives out vapor of acetic acid. It should not be darkened by hydrosulphuric acid or sulphide of ammonium (absence of metals). It contains about 7.6 per cent. of acetate of ammonium."—U. S. In this description no notice is taken of the presence of carbonic acid gas in the liquid, which is evidently intended by the process.

The British Pharmacopœia directs the preparation of a neutral solution which is somewhat stronger: the undiluted acetic acid being used, less carbonic acid is retained by the liquid, and may be expelled by trituration or stirring at first, and toward the close of the reaction by warming the liquid until it has no effect upon test-paper, after which it is to be properly diluted. In place of ammonium carbonate, ammonia-water may be used to effect the neutralization, as directed by the German Pharmacopœia, which requires the neutralized liquid to be heated to boiling for a short time, in order to expel traces of empyreumatic matter likely to be present in the ammonia-water. The description cor-

responds with the one given above, but the solution is to have the specific gravity 1.032–1.034, to contain 15 per cent. of ammonium acetate, and to be not rendered turbid by barium nitrate (absence of sulphate), nor, after acidulation with nitric acid, by silver nitrate (absence of chloride).

Acetic acid decomposes ammonium carbonate, carbonic acid gas being given off and ammonium acetate remaining in solution; $4\text{HCl} \cdot \text{H}_2\text{O}_2 + \text{N}_2\text{H}_{16}\text{C}_4\text{O}_6$ yields $3\text{CO}_2 + 4\text{NH}_4\text{C}_2\text{H}_3\text{O}_2 + 2\text{H}_2\text{O}$. When long kept in contact with air the solution acquires an alkaline reaction.

Off. Prep.—*Mistura ferri et ammonii acetatis, U. S.*

Physiological Action.—Experiments upon animals show that this preparation, in large doses, affects them energetically—in rabbits causing fatal tetanic spasms and dissolution of the gastric mucous membrane. Given to healthy men, it does not appear to occasion any decided symptoms, except a little warmth of the skin and in the abdomen, headache, and loss of appetite. Upon the skin it acts as an irritant, and may even vesicate it. Judged by its apparent effects in disease, it seems to be stimulant, diaphoretic, diuretic, and expectorant, and sometimes causes transient giddiness and exhilaration.

Medical Uses.—It is generally held to be efficient in the forming stage of *catarrh*, *sore throat*, and *muscular rheumatism*, and in the *eruptive fevers* when the eruption is slow to appear. It is the best diaphoretic in epidemic catarrh or *influenza*. In low forms of *fever* it is often of signal advantage, helping to sustain the powers of life until the crisis is past. In this way it is peculiarly valuable in *typhus*, in which, like other appropriate stimulants, it lowers the pulse and temperature, moistens the dry tongue, and moderates the delirium. It is reported to have been peculiarly efficacious in the treatment of epidemic *pseudo-membranous bronchitis*.

In *sick headache* few remedies are so successful as a teaspoonful or two of this solution repeated every hour. In *alcoholic intoxication* it frequently dissipates at once the signs of drunkenness. It is reported to be an efficient remedy in *dysmenorrhœa* and *menorrhagia*. It is an adjuvant in the treatment of scarlatinous *dropsy*, and is perhaps not without advantage in chronic *eruptions of the skin*.

Externally, it is a valuable discentient in *contusions*, *glandular swellings*, *mammary engorgements*, *commencing abscesses*, *hydrarthrosis*, and even acute *hydrocele*. It has been found beneficial in *impetigo capitis*.

The *dose* of the official solution is from $\frac{1}{2}$ fluidounce to $1\frac{1}{2}$ fluidounces (Gm. 15–45), diluted with sweetened water.

LIQUOR AMMONII CITRATIS, *Br.*—SOLUTION OF CITRATE OF AMMONIUM.

Citrate d'ammoniaque liquide, Fr.; Ammoniumcitrat-Lösung, G.

Preparation.—Strong Solution of Ammonium Citrate 5 fl. oz.; Distilled Water sufficient for 20 fluidounces.—*Br. Spec. grav.* 1.062.

LIQUOR AMMONII CITRATIS FORTIOR.—Neutralize citric acid 12 oz. with ammonia 11 fluidounces or sufficient, and add distilled water sufficient to yield 20 fluidounces of product. Store in bottles free from lead.—*Br. Spec. grav.* 1.209.

Citric acid combines with ammonia, forming ammonium citrate and water. The two solutions are clear and colorless, have a saline taste, and should not change either litmus- or turmeric-paper.

Medical Action and Uses.—This solution is perhaps more palatable than solution of acetate of ammonia, but its medicinal effects are in no wise different. *Dose*, from 2 to 4 fluidrachms (Gm. 8–16).

LIQUOR ANTIMONII CHLORIDI, *Br.*—SOLUTION OF CHLORIDE OF ANTIMONY.

Liquor stibii chlorati, Antimonium muriaticum liquidum, Butyrum antimonii (s. stibii), Chloridum (s. Chloruretum) stibicum.—Liquid butter of antimony, *E.*; Chlorure (*Beurre*) d'antimoine liquide, *Huile d'antimoine, Fr.; Spiessglanzbutter, G.*

A solution of SbCl_3 (molecular weight 226.2) in hydrochloric acid.

Preparation.—Purified Black Antimony 1 pound; Hydrochloric Acid 4 pints. Place the black antimony in a porcelain vessel, pour upon it the hydrochloric acid, and,

constantly stirring, apply to the mixture, beneath a flue with a good draught, a gentle heat, which must be gradually augmented as the evolution of gas begins to slacken, until the liquid boils. Maintain it at this temperature for 15 minutes; then remove the vessel from the fire, and filter the liquid through calico into another vessel, returning what passes through first, that a perfectly clear solution may be obtained. Boil this down to the bulk of 2 pints (Imperial), and preserve it in a stoppered bottle.—*Br.*

Hydrochloric acid decomposes sulphide of antimony, with the production of antimonious chloride, which dissolves in the acid liquid, and hydrogen sulphide, which escapes; $\text{Sb}_2\text{S}_3 + 6\text{HCl}$ yields $2\text{SbCl}_3 + 3\text{H}_2\text{S}$. Provision must be made to carry off the offensive gas either through a flue or by working in the open air. The powdered sulphide and the acid may be left in contact for several hours, during which time the reaction will partly take place; the mixture should afterward be slowly heated until the boiling-point is reached and the disengagement of sulphuretted hydrogen ceases. The insoluble mineral impurities are then filtered off, either through calico, or, preferably, through a material which is not corroded by the acid liquid, such as gun-cotton, asbestos, or glass-wool. The arsenic naturally contained in the antimony is partly evolved, and the remainder is removed as arsenious chloride by boiling the filtered liquid and concentrating it as directed, this arsenic compound being much more volatile than the antimonious chloride. The French Codex directs the liquid to be concentrated by evaporation, and the residue to be distilled—an operation requiring great care in case notable quantities of lead chloride be present.

Properties.—It is a yellowish or yellowish-red liquid having the spec. gr. 1.47, and yielding with water a white precipitate of antimonious oxychloride (*powder of Algaroth*), $(\text{SbCl}_3)_2 \cdot 5\text{Sb}_2\text{O}_3$. This precipitate is completely soluble in an aqueous solution of tartaric acid, and the solution, when treated with hydrogen sulphide, yields an orange-brown precipitate of sulphide of antimony, which, when dried at 100°C ., should weigh about 22 grains for every fluidrachm of the official solution. When free from other metals the solution is colorless; as prepared from the crude sulphide, however, it always contains ferric chloride.

Antimonium chloride of the French Codex is a soft white, translucent, crystalline, and very caustic mass, which melts to a clear liquid at 73°C . (163.5°F .) and boils at 223°C . (433.5°F .). On exposure to the air it fumes and absorbs moisture, deliquescent to a clear oily liquid, which is precipitated by more water. The salt is soluble in cold alcohol, and this solution, when boiled, precipitates antimonious oxychloride.

Impurities.—*Lead*, if present, will mostly crystallize from the cold liquid; what remains dissolved may be recognized by a drop of dilute sulphuric acid, which will cause a white precipitate. *Copper* is recognized by the blue color obtained on treating the liquid with an excess of ammonia. *Arsenic* is detected by rendering the liquid strongly alkaline with potassa, adding a little pure zinc, and heating to boiling. The vapors, on coming in contact with filtering-paper moistened with a drop of solution of silver nitrate, will then color the latter black.

Pharmaceutical Uses.—In the preparation of Antimonii oxidum, *Br.*

Surgical Action and Uses.—Butter of antimony is one of the most powerful caustics employed in surgery, and from its readily penetrating into *wounds* has been used to canterize those inflicted by rabid animals and venomous serpents. It has also been applied to *malignant pustule, warts, condylomata, and chancres*. "Pure chloride of antimony has been used as an application to *staphylocoma* by some German surgeons; a camel's-hair pencil or a point of lint is dipped in the deliquescent salt and applied to the tumor until a whitish crust is perceived, when the whole is washed away by means of a large camel's-hair pencil dipped first in milk and afterward into milk and water" (Neligan).

Several instances of poisoning by this preparation are on record in which, besides abrasions of the mouth and throat, or even a charred appearance of these parts, there was more or less complete general collapse. In one case recovery took place after 4 or 5 drachms, and in another after an ounce, had been taken. In a fatal case the dose was 3 ounces, and on inspection after death the interior of the alimentary canal from the mouth down to the jejunum presented a black appearance, as if the parts had been charred (Taylor).

The proper *antidotes* for poisoning by chloride of antimony are chalk and magnesia or its carbonates, combined with demulcent drinks. Tannic acid and the substances containing it are also recommended.

LIQUOR ARSENII ET HYDRARGYRI IODIDI, U. S., Br.—SOLUTION OF IODIDE OF ARSENIC AND MERCURY.

Liquor arsenici et hydrargyri iodidi, U. S. 1870; *Solutio Donovan*.—Donovan's solution, E.; *Soluté d'iodo-arsénite de mercure*, *Liquueur de Donovan*, Fr.; *Jodquecksilber-Arsenik-Lösung*, *Donovansche Tropfen*, G.

Preparation.—Iodide of Arsenic 1 part (41 grains); Red Iodide of Mercury 1 part (41 grains); Distilled Water, a sufficient quantity; to make 100 parts (4100 grains). Triturate the iodides with 15 parts (615 grains or 11 fluidrachms) of distilled water until they are dissolved. Filter the liquid, and pass enough distilled water through the filter to make the solution weigh 100 parts (4100 grains or 9 fluidounces).—*U. S.*

Iodide of arsenium, mercuric iodide, each 45 grains; distilled water sufficient for 10 fluidounces Imperial.—*Br.*

This is a solution of the two iodides in very nearly the proportion of their molecular weights, and containing them mixed, but not chemically combined. The present preparation contains about 4 per cent. more of each of the two iodides than that of 1870.

Properties.—It is of a light-yellow color, has a metallic taste, and gives precipitates with solutions of silver, alkalies, and salts of the alkaloids. The 9 fluidounces represent very nearly 7 grains of metallic arsenic and about 18 grains of mercury.

Medical Uses.—The combination of arsenic and mercury in this preparation was proposed for the treatment of *syphilitic* diseases of the skin, and was thought to be especially useful in those of the squamous form, although mercury alone is apt to aggravate them. Yet many consider that in these cases the compound is more injurious than useful. The efficacy of Donovan's solution is shown in cutaneous affections apparently free from syphilitic taint when they have become chronic and have resisted arsenic alone. Among these may be mentioned *impetigo* and *syccosis*; in the latter it should be associated with epilation. The best authorities deny that it has any curative influence in *lupus*. The *dose* is 5 drops (Gm. 0.30), gradually increased and taken after meals, well diluted.

LIQUOR ATROPIÆ, Br. 1867.—SOLUTION OF ATROPIA.

Soluté d'atropine, Fr.; *Atropin-Lösung*, G.

Preparation.—Take of Atropia 4 grains; Rectified Spirit 1 fluidrachm; Distilled Water 7 fluidrachms. Dissolve the atropia in the spirit, and add this gradually to the water, shaking them together.—*Br. 1867.*

Medical Uses.—This solution contains in each minim $\frac{1}{120}$ grain of atropia. It may be administered hypodermically in the *dose* of 1 minim, and cautiously increased. It is employed for *dilating the pupil* by instilling it into the eye, care being taken, by pressure on the punctum lachrymale, to prevent its passage into the nostril.

LIQUOR ATROPINÆ SULPHATIS, Br.—SOLUTION OF SULPHATE OF ATROPINE.

Soluté de sulfate d'atropine, Fr.; *Schwefelsaure Atropin-Lösung*, G.

Preparation.—Take of Sulphate of Atropine 9 grains (1 part); Camphor-Water $16\frac{1}{2}$ fluidrachms (99 fluid parts). Dissolve.—*Br.*

The two preceding solutions are best prepared in small quantity only, that decomposition, which is likely to result from long keeping, may be prevented. Combining the atropine with benzoic or boracic acid does not, in the experience of Tichborne (1877), prevent the appearance of fungoid growth, but *solution of salicylate of atropine*, made of 2.7 grains of atropine and 1.3 grains of salicylic acid to 1 ounce of distilled water, was found to keep indefinitely. Camphor-water prevents decomposition better than distilled water.

Medical Uses.—This preparation is identical with solution of atropia in its strength, action, uses, dose, and mode of application. For acting upon the iris discs of paper or gelatin impregnated with either solution may be introduced between the eyelid and the eyeball.

LIQUOR BISMUTHI ET AMMONII CITRATIS, Br.—SOLUTION OF CITRATE OF BISMUTH AND AMMONIUM.

Liquor bismuthi.—*Solution of ammonio-citrate of bismuth*, E.; *Soluté de citrate de bismuth ammoniacal*, Fr.; *Wismuth-Ammoniak-Citrat-Lösung*, G.

Preparation.—Take of Citrate of Bismuth 800 grains; Solution of Ammonia, Dis-

tilled Water, of each a sufficiency. Rub the citrate of bismuth to a paste with a little of the water; add the solution of ammonia, gradually and with stirring, until the salt is just dissolved. Dilute with distilled water to form 1 pint (Imperial).—*Br.*

In the former edition of the Br. P. a concentrated solution of bismuth nitrate in nitric acid was mixed with double the quantity of citric acid theoretically necessary for the formation of bismuthous citrate; and this acid liquid was neutralized with ammonia. Thus prepared, the solution contained ammonium citrate and bismuthous citrate, or a double salt of these two compounds, and in addition thereto a notable quantity of ammonium nitrate. N. G. Bartlett (1865), however, showed—and his observations were corroborated by Méhu (1873)—that the neutral bismuthous citrate dissolves in ammonia, and that on evaporation a dry salt is obtained which is again soluble in water, and for which Rother (1876) gives the formula $(\text{NH}_4)_3\text{C}_6\text{H}_5\text{O}_7\cdot\text{Bi}_3\text{HIO}$. These observations have led to several modifications of the former formula, by which contamination with ammonium nitrate is at the same time avoided. These modifications are based upon the preparation of *bismuth citrate*—1, by double decomposition between bismuth nitrate and potassium or sodium citrate; or 2, by first preparing bismuthous hydrate or subcarbonate, and treating this with the equivalent quantity of citric acid; or 3, as suggested by Rother, by boiling for a short period equivalent quantities (10 parts) of bismuth subnitrate and (7 parts) of citric acid with some water. This latter process has been adopted by the U. S. P. (see page 318), while the Br. P. prepares its *Bismuthi citras* from a solution of bismuthous nitrate in nitric acid, diluted with water as much as possible, by precipitating it with sodium citrate. These precipitated citrates frequently contain small quantities of bismuthous chloride and sulphate as impurities, and these two salts remain insoluble on treating the citrate with ammonia, which should be added merely until it remains permanently in slight excess. By filtering, weighing the dried undissolved residue, and deducting it from the original weight of the bismuthous citrate, the actual weight of the latter is readily ascertained, and the strength of the solution may thus be adjusted.

BISMUTHI ET AMMONII CITRAS. Br. is prepared from the above solution (see p. 318), the heat for drying in scales being limited to 37.8°C . (100°F .) to avoid loss of ammonia.

Properties.—The solution of the British Pharmacopœia is colorless, and has a saline slightly styptic taste and the specific gravity 1.07. It is neutral or slightly alkaline to test-paper, and mixes with water without change. Potassa yields a precipitate of bismuth hydrate, and liberates ammonia: hydrochloric acid produces a precipitate of basic salt, which is redissolved by an excess of acid. 2 fluidrachms of the official solution, treated with sulphuretted hydrogen, yield a black precipitate, which after drying weighs about 7 grains. Each fluidrachm represents 3 grains of bismuthous oxide.

Medical Uses.—If, as we have endeavored to show elsewhere, the action of bismuth is entirely local and depends upon its insolubility, the use of its soluble salts is irrational. Yet the solubility of this preparation is set forth as a ground of its superiority over the oxide and the subnitrate! As an astringent it is quite superfluous, although it seems to have been employed in cases of flaccidity of the *vagina*, *rectum*, etc. The official dose is stated to be from 30 minims to 1 fluidrachm (Gm. 2–4).

LIQUOR CALCIS, U. S., Br.—SOLUTION OF LIME.

Aqua calcariæ, P. G.; *Aqua calcariæ ustæ*, *Aqua calcis*, *Calcariæ soluta*, *Oxydum calcicum aqua solutum*.—*Lime-water*, E.; *Eau (Liquueur) de chaux*, Fr.; *Kalkwasser*, G.

An aqueous solution containing about 0.16 per cent. of hydrate of calcium, $\text{Ca}(\text{HO})_2$.

Preparation.—Lime 1 part ($\frac{1}{2}$ oz. av.); Water. Distilled Water each a sufficient quantity. Slake the lime by the gradual addition of 6 parts (3 ounces) of water, then add 30 parts (15 ounces) of water, and stir occasionally during half an hour. Allow the mixture to settle, decant the liquid, and throw this away. Now add to the residue 300 parts (150 oz. av. or 9 pints) of distilled water, stir well, wait a short time for the coarser particles to subside, and pour the liquid, holding the undissolved lime in suspension, into a glass-stoppered bottle. Pour off the clear liquid when wanted for use.—*U. S.*

Wash slaked lime 2 oz. with distilled water until the filtrate acidulated with nitric acid is not rendered turbid by nitrate of silver. Put the washed lime into a stoppered bottle containing 1 gallon of distilled water, and shake well for 2 or 3 minutes. After 12 hours the excess of lime will have subsided, and the clear solution may be drawn off with a siphon as it is required for use, or transferred to a green glass bottle furnished with a well-ground stopper.—*Br.*

When water is added to burned lime or calcium oxide, this is converted into *calcium hydrate*, Ca_2HO , which dissolves in the excess of water. If used for this purpose, the

lime should be prepared from marble, when it will be nearly pure; but if made from ordinary limestone it usually contains alkalies which are readily soluble in water, hence it should be treated with a portion of the water, and this rejected to remove the impurities mentioned. The water should be kept, at a low temperature, upon the lime to retain the solution saturated, and this should be drawn off as needed

Properties.—Lime-water is a clear, colorless, inodorous solution of a slight alkaline disagreeable taste, but of a strong alkaline reaction to test-paper; its specific gravity is 1.0015 at 15° C. (59° F.) When exposed to air it becomes covered with a pellicle of calcium carbonate; the same compound is formed with the loss of the alkaline reaction if carbonic acid gas is passed through the solution and the solution heated to expel the excess of the gas (absence of alkalies or alkali carbonates). If lime-water is heated to boiling, it becomes turbid from the separation of some calcium hydrate, which dissolves again on cooling. On the addition of test-solution of oxalic acid, lime-water yields a white precipitate of calcium oxalate, which is insoluble in acetic, but soluble in hydrochloric, acid.

Tests.—Since at 15° C. (59° F.) lime requires about 780 parts of water for solution, 1 fluidounce (U. S. measure) of lime-water contains 0.57 grain of lime or 0.75 grain of calcium hydrate, which is equal to .125 and .165 per cent. respectively. At 21° C. (70° F.) 800 parts of water are required for solution, indicating .125 per cent. of calcium oxide or .166 per cent. of calcium hydrate—not 0.15 per cent. of the latter, as stated in the Pharmacopœia; a saturated solution of lime of this strength is obtained at 32° C. (90° F.). According to Thomas Maben (1883), 1 part of CaO is soluble

	10°	20°	30°	40°	60°	80°	99°C.
in	770	791	862	932	1136	1362	1650 parts of water,
or	.129	.126	.116	.107	.088	.073	.06 per cent. CaO.

On mixing 100 Ccm. of lime-water with 4.4 Ccm. of volumetric solution of oxalic acid, the liquid does not acquire an acid reaction, indicating at least .123 per cent. of CaO. "10 ounces require for neutralization at least 180 grain-measures of the volumetric solution of oxalic acid, which corresponds to 5 grains of calcium oxide (CaO)."—*Br.*

Pharmaceutical Uses.—In preparing Argenti oxidum, Lotio hydrargyri flava, Lotio hydrargyri nigra, *Br.*, and Linimentum calcis, *U. S., Br.*

Medical Action and Uses.—Lime-water is destitute of caustic qualities, but is astringent and styptic, diminishing more or less the secretion of parts to which it is directly applied and of the mucous membranes and glands when taken internally. It is a valuable lotion in various diseases of the skin, especially *eczema capitis* and *ulcers*. In the former the affected part should be thoroughly cleansed with warm water and soap before the lime-water is applied. In all cases of chronic *mucous* or *purulent discharges* from the nostrils, fauces, auditory canal, vagina, urethra, or rectum, it is one of the simplest and best washes. It is said to destroy *ascarides of the rectum*. With flaxseed oil or sweet oil it forms the official liniment so useful in the treatment of *burns*.

Internally, as already indicated, it appears to escape in part the neutralizing influence of the gastric acids, for it has long been used to diminish the mucous secretion in *chronic bronchitis*, and to modify the urine and the lining membrane of the urinary passages in *calculous* and other disorders of the urino-genital organs. In vesical diseases lime-water is sometimes injected into the bladder through a catheter after properly cleansing the organ. It would seem, whether employed in the one or the other manner, to act by diminishing the irritability of the vesical mucous membrane. Lime-water is one of the most useful remedies for excessive *vomiting* produced by irritability or ulcer of the stomach, especially when the matters rejected are very acid. In the vomiting of tubercular phthisis and of simple and cancerous gastric ulcer milk with lime-water is sometimes the only nutriment that can be retained. The constipation that results from the internal use of lime-water, as well as its beneficial operation in chronic bronchitis, proves that it is not fully acidified in the stomach. In *diarrhœa* attended with acid stools and the associated colic and tympanites belonging to acid gastro-intestinal fermentation, and which is so prevalent during hot seasons, especially among infants, lime-water added to their milk in the proportion of from one-fourth to one-half is a very efficient remedy. The *aphthous* condition of the mouth and fauces, and the *thrush* fungus that forms there under these circumstances, are often removable by lime-water. In *chronic diarrhœa*, dependent on whatever cause, this solution, given with milk as the almost exclusive food, will usually mitigate, and in appropriate cases cure, the disease. The most signal triumphs of this simple method are achieved in *chronic dysentery* and in cases of *typhoid fever* protracted

by the persistence of the intestinal ulcers. Even in tubercular *phthisis* it sometimes suspends the discharges for a considerable time. In all these affections it diminishes *tympanites*, and in certain cases in which that symptom appears to be the result of intestinal fermentation, lime-water is one of the best remedies. This preparation has been extolled as a remedy for *diabetes*, and the highest testimony in its favor exists, so far as relates to its power of lessening the secretion of sugar. It in like proportion diminishes thirst and voracious appetite. It should be given with milk, or, if that is contraindicated, with cream, and in quantity not less than 1 or 2 pints daily. In *hydruria* or diabetes insipidus it is more efficacious still. It has been recommended in *rachitis* and *osteomalacia*, and is very useful in gouty (acid) *dyspepsia*, especially when taken during the first stages of digestion. The *cutaneous eruptions* so often associated with gouty disorders are usefully treated by the internal use of lime-water.

The demonstration that false membranes are soluble in lime-water led to the use of gargles and the spray of this liquid and the vapors of slaked lime in *pseudo-membranous pharyngitis* (diphtheria) and in *laryngitis* and *bronchitis* of the same type. The result has been the cure of a large number of cases in which the nature of the disease was abundantly demonstrated by inspection or by the rejection of false membranes. To be successful the inhalation should be almost uninterrupted. As often as possible the patient should be confined in a dense vapor of slaking lime, and with this the use of atomized lime-water should be alternated, while the room is kept filled with the vapor. Other treatment, except stimulants, is of little use. It may perhaps be questioned whether the good results of this method are due to the solvent action of the lime or to the softening influence of the watery vapor which holds it in solution. Possibly, both influences contribute to the result, but the latter is probably the most efficient.

Lime-water is an appropriate antidote to *arsenious acid*, with which it forms an innocuous compound.

The *dose* of lime-water is from $\frac{1}{2}$ ounce to 6 ounces (Gm. 32–190), given from one to four times a day with an equal quantity of milk or weak animal broth.

LIQUOR CALCIS CHLORINATÆ, Br.—SOLUTION OF CHLORINATED LIME.

Chlorure de chaux liquide, Fr.; *Chlorkalk-Lösung*, G.

Preparation.—Take of Chlorinated Lime 1 pound; Distilled Water 1 gallon. Mix well the water and the chlorinated lime by trituration in a large mortar, and, having transferred the mixture to a stoppered bottle, let it be well shaken several times for the space of 3 hours. Pour out now the contents of the bottle on a calico filter, and let the solution which passes through be preserved in a stoppered bottle.—Br.

The solution has the odor, taste, and general properties of chlorinated lime (see page 361). The Br. P. requires the solution to contain at least 1.9 (about 2) per cent. of available chlorine, which is ascertained by the following test: 80 grains by weight, mixed with 20 grains of iodide of potassium dissolved in 4 fluidounces of water, when acidulated with 2 fluidrachms of hydrochloric acid give a red solution, which requires for the discharge of its color 450 grain-measures of the volumetric solution of hyposulphite of soda.

Medical Action and Uses.—This solution is convenient as a *deodorizer* of decomposing organic matter, as an *excitant* of the skin in low fevers, as a stimulant of chronic *cutaneous eruptions*, and for the various purposes enumerated under CHLORINATED LIME.

LIQUOR EPISPASTICUS, Br.—BLISTERING LIQUID.

Linimentum cantharidis, Br. 1864.—*Liquueur vésicant*, Fr.; *Blasenzichende Flüssigkeit*, G.

Preparation.—Take of Cantharides, in powder, 5 ounces; Acetic Ether a sufficiency. Mix the cantharides with 3 fluidounces of acetic ether; pack in a percolator, and at the expiration of 24 hours pour acetic ether over the contents of the percolator, and allow the solution to pass slowly through until 20 fluidounces are obtained. Keep the liquid in a stoppered bottle.—Br.

As formerly made with acetic acid and ether, the blistering liquid contained the entire amount of cantharidin in solution. Tiehborne preferred to use in place of acetic acid an equivalent amount of glacial acetic acid, as thereby less water is introduced into the powder. Brady has shown that when spontaneously evaporated from the skin the film left is not uniform, but thickest at the circumference. Deane (1876) recom-

mended the discarding of the official solvents, and the substitution of acetic ether, which dries more uniformly and takes up a larger amount of cantharidin.

Medical Action and Uses.—This liquid is intended to produce a rapid vesication, which is effected chiefly by the acetic acid, although the irritation is maintained by the cantharides. It should be well rubbed into the skin with a small mop or piece of sponge attached to a handle, until redness is produced, and should be used only on limited portions of the skin.

LIQUOR FERRI ACETATIS, *U. S.*, *Br.*—SOLUTION OF ACETATE OF IRON.

Liquor ferri acetici, P. G.—*Solution of ferric acetate*, E.; *Acétate ferrique liquide*, Fr.; *Ferriacetat-Lösung*, G.

An aqueous solution of ferric acetate $\text{Fe}_2(\text{C}_2\text{H}_3\text{O}_2)_6$; molecular weight 465.8—containing 33 per cent. of the anhydrous salt.

Preparation.—Solution of Tersulphate of Iron 100 parts (25 oz. av. or 18 fluidounces $1\frac{1}{2}$ fluidrachms); Glacial Acetic Acid 26 parts ($6\frac{1}{2}$ oz. av. or 6 fluidounces); Water of Ammonia 80 parts (20 oz. av. or 20 fluidounces); Water, Distilled Water, each a sufficient quantity; to make 100 parts (25 oz. av.). To the water of ammonia, diluted with 200 parts (50 oz. av. or 3 pints) of cold water, add, constantly stirring, the solution of tersulphate of iron, previously diluted with 350 parts ($87\frac{1}{2}$ oz. av. or $5\frac{1}{4}$ pints) of cold water. Pour the whole on a wet muslin strainer, allow the precipitate to drain, then return it to the vessel, and mix it intimately with 600 parts (150 oz. av. or 9 pints) of cold water; again drain it on the strainer, and repeat the operation until the washings cause but a slight cloudiness with test solution of chloride of barium. Then allow the excess of water to drain off, and press the precipitate, folded in the strainer, until its weight is reduced to 70 parts ($17\frac{1}{2}$ oz. av.) or less. Add the precipitate to the glacial acetic acid contained in a capacious porcelain capsule, and stir occasionally until the oxide is entirely dissolved. Finally, add sufficient cold distilled water to make the solution weigh 100 parts (25 oz. av.), and filter if necessary. Solution of acetate of iron should be kept in well-stopped bottles protected from light.—*U. S.*

This formula is modelled after that of the German Pharmacopœia for 1872, but yields a product differing from it not only in strength, but also in composition. The first step is the precipitation of ferric hydrate, which must be accomplished at a low temperature, the iron solution being poured slowly, and with continued stirring, into the ammoniacal liquid, which must remain in slight excess, and the precipitate being washed with cold water by decantation until barium salts show scarcely any reaction with the clear liquid. After draining the precipitate upon a strainer, this is folded and pressure applied to it very gradually—an operation which requires patience to avoid bursting of the press-cloth. The pressure should be very slowly increased until the residue no longer adheres to the cloth as a soft pulpy mass, but may be readily removed in the form of a somewhat firm cake, the weight of which should not exceed 70 parts ($17\frac{1}{2}$ oz. av.). It is then transferred to a glass or porcelain vessel and somewhat broken up with a porcelain spatula, when the glacial acetic acid may be added to it in small portions to avoid heating of the mixture; this is set aside in a cool and dark place, occasionally stirred, and after solution has been effected diluted with distilled water until it weighs 100 parts (25 oz. av. = 20 $\frac{3}{4}$ fluidounces). It is advisable to allow the liquid to settle, to pour off the clear portion from any slight sediment that may be present, and to filter the small quantity of turbid liquid by itself. (For formula of *Br. P.*, see p. 1663.)

Properties.—Solution of ferric acetate is “a dark red-brown, transparent liquid, of an acetous odor, a sweetish, faintly styptic taste, and a slightly acid reaction; sp. gr. 1.160. The diluted solution affords a brown-red precipitate with water of ammonia, and a blue precipitate with test solution of ferrocyanide of potassium. When heated with sulphuric acid the solution evolves acetous vapors.”—*U. S.* On heating the liquid a red-brown precipitate is produced, which does not redissolve on cooling. If the solution be largely diluted with water until it has a mere yellowish color, the addition of solution of potassium sulphocyanide will occasion a blood-red color. On exposure to the light a partial reduction to ferrous salt takes place. As prepared by the pharmacopœial directions, and provided the acetic acid be of the proper strength, the liquid will be a solution of normal ferric acetate having the composition given above. The ferric hydrate, however, will completely dissolve in two-thirds the quantity of acid ordered, the salt then dissolved having the composition $(\text{FeHO})_2(\text{C}_2\text{H}_3\text{O}_2)_4$; and this is the compound which has been largely employed in Europe. It is more readily affected than the preceding by the influ-

ence of light and heat, and is more easily decomposed, even in the dark, with the formation of a brown precipitate, if the ferric hydrate had not been thoroughly washed; precipitates which have been produced under the circumstances indicated are not dissolved on the addition of acetic acid.

The German Pharmacopœia recognizes a solution of the basic acetate, mixed with about 12 per cent. of the normal acetate; this solution has the specific gravity 1.081–1.083, and contains between 4.8 and 5 per cent. of iron.

Tests.—The tests of purity are in both pharmacopœias substantially alike. If a few drops of the liquid be added to freshly-prepared test solution of ferrieyanide of potassium, the mixture should acquire a pure greenish-brown color without a trace of blue (absence of ferrous salt). If the iron be completely precipitated from the solution by an excess of ammonia, a portion of the filtrate should not yield a white or a dark-colored precipitate with hydrosulphuric acid (zinc, copper); another portion should leave no fixed residue on evaporation and gentle ignition (fixed alkalies, alkaline earths, zinc, copper); and a third portion of the filtrate on being acidulated with nitric acid should not be rendered turbid by test solution of barium nitrate (sulphate) or of silver nitrate (chloride). “10 Gm. of the solution mixed with a few drops of nitric acid, carefully evaporated and ignited, should yield a residue weighing 1.13 Gm.”—*U. S.* If all loss has been avoided in making the solution, the residue left on ignition will weigh 1.147 Gm.

Pharmaceutical Uses.—Solution of ferric acetate, diluted with water, may be used as a test for free mineral acids, which change the color from red to brown.

FERRI ACETAS. The clear solution obtained in the cold by saturating acetic acid with ferric hydrate, decanting, instead of filtering from the insoluble matter, and evaporated at a temperature of about 60° C. (140° F.), leaves a scaly basic salt, which is again soluble in cold water.

Off. Prep.—*Tinctura ferri acetatis, U. S.*

Medical Action and Uses.—Besides possessing the special virtues of chalybeate preparations, this compound is astringent, and indeed may be used as a styptic, both internally and topically. The *dose* of the German preparation after which this one is formed is from 5 to 15 grains (Gm. 0.06–1) as a tonic or internal astringent. In much larger doses and well diluted with water it has been given as an antidote to *arsenious acid*.

LIQUOR FERRI CHLORIDI, *U. S.*—SOLUTION OF CHLORIDE OF IRON.

Liquor ferri perchloridi fortior, Br.; Liquor ferri sesquichlorati, P. G.; Liquor ferri muriatici oxydati, Ferrum sesquichloratum solutum.—*Solution of ferric chloride. Strong solution of perchloride of iron, E.; Solution de perchlorure de fer, Chlorure ferrique liquide, Fr.; Eisenchloridlösung, Flüssiges Eisenchlorid, G.*

The specific gravities of the official solutions of ferric chloride are—1.405 *U. S.*, 1.42 *Br.*, 1.280 to 1.282 *P. G.*, 1.26 *F. Cod.*, and they contain 37.8 per cent. *U. S.* (with some free hydrochloric acid), about 39 per cent. *Br.*, 29.8 per cent. *P. G.*, and 26 per cent. *F. Cod.*, of anhydrous ferric chloride.

Preparation.—Iron, in the form of fine wire and cut into small pieces, 15 parts (3½ oz. av.); Hydrochloric Acid 86 parts (21½ oz. av.); Nitric Acid, Distilled Water, each a sufficient quantity; to make 100 parts (25 oz. av.). Put the iron wire into a flask capable of holding double the volume of the intended product. Pour upon it 54 parts (13½ oz. av.) of hydrochloric acid previously diluted with 25 parts (6¼ oz. or 6 fluidounces) of distilled water, and let the mixture stand until effervescence ceases; then heat it to the boiling-point, filter through paper, and, having rinsed the flask and iron wire with a little boiling distilled water, pass the washings through the filter. To the filtered liquid add 27 parts (6¾ oz. av.) of hydrochloric acid, and pour the mixture, slowly and gradually, in a stream, into 8 parts (2 oz. av.) of nitric acid contained in a capacious porcelain vessel. After effervescence ceases apply heat, by means of a sand-bath, until the liquid is free from nitrous odor. Test a small portion with freshly-prepared test solution of ferrieyanide of potassium. Should this reagent produce a blue color, add a little more nitric acid and evaporate off the excess. Finally, add the remaining 5 parts (1¼ oz. av.) of hydrochloric acid and enough distilled water to make the whole weigh 100 parts (25 oz. av. or 17 fluidounces and 1 fluidrachm).—*U. S.*

Mix iron wire 4 oz., hydrochloric acid 12½ fl. oz., and water 7 oz.; when effervescence ceases, heat to boiling, filter, rinse the flask and contents with a little water, and pour this over the filter; add to the filtrate hydrochloric acid 7 fl. oz.; then pour the solution in a slow, continuous stream into 1½ fl. oz. of nitric acid, the evolution of red fumes being

promoted, if necessary, by a slight application of heat. Evaporate the product until no more nitrous fumes escape and a precipitate begins to form; then add hydrochloric acid 1 fl. oz. and sufficient water to produce 17½ fl. oz. of the solution.—*Br.*

LIQUOR FERRI PERCHLORIDI, *Br.* Mix strong solution of perchloride of iron 1 fluidounce with distilled water sufficient for 4 fluidounces. Its spec. grav. is 1.11.

The reactions which take place in the preparation of ferric chloride and the proper manipulations to ensure success have been described. (See FERRI CHLORIDUM, page 676.) The solution of the U. S. Pharmacopœia differs from the similar solutions of the other pharmacopœias in containing 1.6 per cent. uncombined HCl, or 500 grains of official hydrochloric acid, to the pint; the difference in density has been stated above.

Properties.—Solution of ferric chloride is a reddish-brown liquid, which has a faint odor of hydrochloric acid, an acid reaction, and a strongly styptic taste. It may be mixed with water and alcohol in all proportions without producing a precipitate. Diluted with water, it gives a brown precipitate with ammonia or potassa, a white one with silver nitrate (chloride), and a dark-blue precipitate of Prussian blue with potassium ferrocyanide. It is not altered by exposure to the sunlight, except in the presence of various organic matters, by which the salt is partly reduced to ferrous chloride; and it remains clear when heated to boiling unless ferric oxychloride be present, when it becomes turbid, a slight turbidity being best observed in reflected light. On being evaporated to dryness a reddish-brown salt is left, which at a red heat is partly decomposed and partly volatilized.

Tests.—The same reactions which are used for determining the purity of the salt (see FERRI CHLORIDUM, page 676) are likewise employed for this solution. On adding a crystal of ferrous sulphate to a little of the solution, and afterward a few drops of strong sulphuric acid, a black color should not be produced near the crystal (absence of nitric acid). A freshly-prepared solution of potassium ferri-cyanide should color the solution olive-brown, but not blue (ferrous salt). Diluted with water and boiled, it acquires a darker color, but remains clear (oxychloride). Test solution of barium chloride should not cause a precipitate (sulphate). Mixed with excess of ammonia-water and filtered, the liquid should be colorless (copper); a portion of the filtrate, tested with hydrosulphuric acid or acidulated with acetic acid and tested with potassium ferrocyanide, should not be precipitated (copper, zinc); another portion of the filtrate, evaporated to dryness and ignited, should leave no residue (alkalies, alkaline earths, zinc, copper). Paper saturated with solution of starch and zinc iodide on being held near the surface of the solution should not acquire a blue color (free chlorine). “10 Gm. of the solution, when completely precipitated by excess of water of ammonia, yield a precipitate which, when washed, dried, and ignited, should weigh 1.86 Gm.”—*U. S.* 2 fluidrachms of the solution, diluted with water, and mixed with an excess of ammonia-water, yield a reddish-brown precipitate which, when washed and ignited, weighs between 30 and 32 grains.—*Br.*

Pharmaceutical Uses.—MARTIN'S HÆMOSTATIC, which is used in France, consists of selected pieces of spunk which are saturated with ferric chloride.

ADRIAN'S HÆMOSTATIC is made by dissolving 15 Gm. of sodium chloride in 60 Gm. of water, and adding 25 Gm. of solution of ferric chloride specific gravity 1.26.

FERRUM ALBUMINATUM is a compound of ferric chloride and albumen which has been recently introduced in Europe, and for which J. Biel (1878) has given the following process: 10 Gm. of dry soluble egg-albumen are dissolved in 100 Gm. of distilled water; the clear solution is mixed with 1.75 Gm. of crystallized ferric chloride (see page 675) previously dissolved in 24 Gm. of distilled water; 20 Gm. of 90 per cent. alcohol are now added, and sufficient water to make 200 Gm. This concentrated solution will keep in the dark without alteration; for dispensing, to obtain the *Liquor ferri albuminati*, 1 part of it is diluted with 4 parts of distilled water, and then contains 0.033 per cent. of metallic iron, the strength generally adopted in Europe. It is more convenient, however, to evaporate the concentrated solution at a temperature not exceeding 40° C. (104° F.), when the compound is obtained in golden-yellow transparent scales containing 3.34 per cent. of iron, and yielding the solution by dissolving them in one hundred times their weight of distilled water.

LIQUOR FERRI PERCHLORIDI, *Br.*, Solution of perchloride of iron (see formula on page 900), is intended to take the place of the tincture of ferric chloride, as it retains the iron salt in an unchanged condition.

Off. Prep.—Tinct. ferri chloridi (perchloridi), *U. S.*, *Br.*

Action and Medical Uses.—The action of a poisonous dose of ferric chloride is described by Béranger-Féraud and Porte as follows: An acrid and styptic taste in the

mouth is followed by epigastric distress, vomiting, colic, diarrhoea with bloody stools, diminution or suppression of urine, cramps and paresis of the legs, cerebral congestion with delirium or collapse, labored breathing, and general cyanosis. After death the mucous membrane of the mouth and throat is dry and hard, and the saliva is mixed with black particles. After a very large dose of a concentrated solution of the salt eschars may be found in the stomach (*Annales d'Hygiène publique*, Avril et Juin, 1879). The local effects of the preparation are illustrated by the following: In a case of epistaxis a druggist tamponned the nasal passages for several days and repeatedly with a ferric chloride solution. The patient died, and at the autopsy gangrenous inflammation of the upper air-passages was observed, with iron stains extending through the cribriform plate of the ethmoid bone to the arachnoid membrane of the brain (*Phila. Med. Times*, xi. 576). It is used chiefly for the styptic and astringent qualities which it possesses in a high degree. Its efficiency as an internal medicine is displayed in various *passive hæmorrhages*, particularly of the stomach, bowels, uterus, and urinary passages. It is useful in several profluvia, as *leucorrhœa*, *hydruria*, nocturnal *incontinence of urine*, and *vesical catarrh*. It is reported to control *seminal emissions* due to irritability of the urethra or spermatic ducts. In chronic *dysentery* it is one of the best of the astringent medicines appropriate to that affection; it may be prescribed internally and by enema. This preparation is more frequently employed locally as a styptic and astringent in *epistaxis*, hæmorrhage from *leech-bites*, from the jaw after the *extraction of teeth*, from the *tonsils*, from *cancer of the uterus*, from the *umbilical cord*, from the rectum in *hæmorrhoids*, from the uterus after *abortion*, and from *vascular growths* in the cavity of that organ. It is of interest to learn, if possible, in what manner the solution acts in arresting hæmorrhage. Undoubtedly it coagulates the blood itself. If a small artery is allowed to bleed into a saucer containing a mixture of 2 parts liq. ferri perchlor. (*B. P.*) and 1 of water, this mixture converts almost instantaneously six or eight times its bulk of blood into a tough, hard clot, and for a long time preserves it from putrefaction (Connel). But Broca has shown that this coagulating action is not instantaneous, but needs about half a minute for its completion; so that if the liquid is applied to a part from which the blood is flowing freely its styptic influence cannot be exerted upon the vessels from which the blood escapes. But such an influence is essential to an arrest of the hæmorrhage. Hence in applying it with this object every effort must be made by pressure and otherwise to suspend for a time the escape of blood.

One of its most valuable applications is that for the arrest of *post-partum hæmorrhage* caused by uterine inertia. Dr. Barnes, who first brought it into vogue, made use of a mixture of $\frac{1}{2}$ pint of the stronger solution of the chloride (*B. P.*) with $1\frac{1}{2}$ pints of water. He directed that a tube about 9 inches long should be carried by the hand to the fundus of the uterus previously freed from coagula, and that the liquid should be very slowly injected, care being taken that no air accompanied it. Basing his judgment on clinical observation alone, he declared that his conviction of the utility of this operation was too deep to permit him to hesitate to pursue it or to urge others to do the same. Such appears to have been the general estimate of the operation by the gynecologists of London, although even in that city several cases of death were attributed to its use by Drs. Bantock, Protheroe, Smith, and Snow Beck. Indeed, the last-named gentleman stated that he had seen nine or ten cases in which death resulted from the injection of solution of chloride of iron into the uterus to arrest hæmorrhage. In Edinburgh the great majority of leading obstetrical practitioners agreed that its employment for this purpose is either useless or worse than useless. Some of those who condemn the injection into the uterus of a solution of chloride of iron advocate the introduction into the organ of the hand containing a sponge saturated with a solution of equal parts of the tincture and water, and the expression there of the liquid after the removal of the clots as far as possible. Pollard ascribes the grave consequences of the injection of the solution into the uterus to its escaping into the peritoneal cavity from the Fallopian tubes or to its entering the uterine veins, and causing either embolism or phlegmasia alba dolens (*British Med. Jour.*, Apr. 24 and May 1, 1880). In *pulmonary hæmorrhage* a weak solution of the chloride has been successfully used in the form of an atomized spray. It may be employed to check *gastric hæmorrhage* in any of the various conditions in which that accident occurs. This powerful styptic has been used to cure *aneurisms*, varicose, sacculated, and others; but, although the operation is successful in coagulating the blood in the tumor, it has so often happened either that the tumor suppurated, or that purulent infiltration took place around it, or that fatal embolism occurred, that the operation is no longer considered warrantable. (Compare *Med. Record*, xxiii. 672.) It has been most

successful in erectile tumors of the scalp, and safest when the tumors, previously blistered or not, have been covered with compresses wet with the astringent solution. *Varicose veins* have been treated by injections of this preparation, pressure being maintained between the point operated upon and the heart. In chronic *ophthalmia* with varicose enlargement of the blood-vessels it affords probably the best chance of cure. As a local application in *diphtheria* it appears to excel all other stimulants and caustics. In the same manner it cures *chilblains* and is advantageous in *zoma*. It is useful in repressing fungous granulations everywhere, but especially in cases of *ingrown toe-nail* and in ulceration of the *gums*. It also forms one of the best dressings for *hospital gangrene*, hardening the tissues and correcting the fetor. A solution of 1 part of the chloride in 2 of water has been applied with alleged curative effects in certain *serofulous ulcers* that had resisted all other treatment (*Bull. de therap.*, xcix. 190). A weak solution (one-sixteenth) has been used as an injection for the radical cure of *hydrocele*. In *prolapse of the rectum* it has been efficiently employed, the protruding bowel being well painted with the solution and then reduced, after which it is retained by means of a tampon moistened with a diluted solution of the medicine. *Dose*, from 1 to 10 minims (Gm. 0.06–0.60), mixed with syrup and largely diluted.

As the teeth are very actively and injuriously attacked by this preparation, they should be carefully guarded against its action by administering the liquid through a glass tube and by thoroughly washing the month after its use.

Albuminate of iron has been used by Donitz in Japan both internally and hypodermically in the treatment of "kakke" (*Medical Record*, xvi. 515). The preparation does not seem to have been approved elsewhere.

LIQUOR FERRI CITRATIS, U. S.—SOLUTION OF CITRATE OF IRON.

Liquor ferri citrici, Citrus ferricus liquidus.—*Citrate de fer liquide*, Fr.; *Eisencitrat-Lösung, Flüssiges Eisencitrat*, G.

An aqueous solution of ferric citrate, $\text{Fe}_2(\text{C}_6\text{H}_5\text{O}_7)_2$; molecular weight 489.8—containing about 35.5 per cent. of the anhydrous salt.

Preparation.—Solution of Tersulphate of Iron 105 parts ($10\frac{1}{2}$ oz. av.); Citric Acid 30 parts (3 oz. av.); Water of Ammonia 84 parts ($8\frac{1}{2}$ oz. av. or $8\frac{1}{2}$ fluidounces); Water a sufficient quantity; to make 100 parts (10 oz. av.). To the water of ammonia, previously diluted with 200 parts (20 oz. av. or $19\frac{1}{2}$ fluidounces) of cold water, add, constantly stirring, the solution of tersulphate of iron, previously diluted with 1000 parts (100 oz. av. or 6 pints) of cold water. Pour the whole on a wet muslin strainer, allow the precipitate to drain, then return it to the vessel, and mix it intimately with 1200 parts (120 oz. av. or $7\frac{1}{4}$ pints) of cold water. Again drain it on a strainer, and repeat the operation until the washings cause but a very slight cloudiness with test solution of chloride of barium; then allow the excess of water to drain off. Transfer the moist precipitate to a porcelain dish, add the citric acid, and heat the mixture, on a water-bath, to 60°C . (140°F), stirring constantly, until the precipitate is dissolved. Lastly, filter the liquid and evaporate it, at the above-mentioned temperature, until it weighs 100 parts (10 oz. av.)—U. S.

The first part of the process consists in preparing ferric hydrate; the reaction has been explained (see page 688). The hydrate retains a considerable quantity of water, so that on the addition of citric acid the mixture becomes liquid as the acid is dissolved and ferric citrate formed. The solution is aided by the application of heat, which should never exceed 66°C . (151°F), but is best kept at 60°C . (140°F) to prevent decomposition. The digestion must be continued for several hours until the acid has taken up as much iron as can combine with it, when it is filtered and evaporated as directed.

Properties.—The solution is inodorous, has a dark-brown color, a slightly ferruginous taste, an acid reaction, and the specific gravity 1.260. When evaporated spontaneously or at a moderate heat in thin layers it forms transparent, garnet-red scales, which are readily detached from the glass or porcelain plate; 100 parts of the solution should yield 43 to 44 parts of scales, and these, on being incinerated, should leave 11 parts of incombustible residue. The solution is rendered darker, but is not precipitated, by alkalis in the cold, but when boiled with potassa or soda a red-brown precipitate of ferric hydrate is produced, and the filtrate, if neutralized with acetic acid and then boiled with test solution of calcium chloride, yields a white granular precipitate of calcium citrate. The solution gives with potassium ferrocyanide a greenish-blue precipitate, which becomes dark-blue on the addition of hydrochloric acid.

Tests.—On boiling the solution with potassa or soda, ammoniacal vapors should not

be given off. On the addition of a few drops of hydrochloric acid, followed by a concentrated solution of potassium acetate, a crystalline precipitate should not be produced (absence of tartrate). On evaporating the solution to dryness and igniting the residue the ash left should not have an alkaline reaction (alkalies).

Pharmaceutical Uses.—In preparing *Ferri citras* and *Ferri et ammonii citras*, *U. S.*

Medical Uses.—This solution forms a convenient mode of dispensing citrate of iron. *Dose*, 10 minims or about 5 grains (Gm. 0.60 or Gm. 0.30) of the salt.

LIQUOR FERRI ET QUININÆ CITRATIS, *U. S.*—SOLUTION OF CITRATE OF IRON AND QUININE.

Liquor chinini ferro-citrici.—*Soluté de citrate de fer et de quinine*, Fr.; *Ferrichinincitrat-Lösung*, G.

Preparation.—Citrate of Iron and Ammonium 65 parts (780 grains = 13 drachms); Quinine, dried at 100° C. (212° F.) until it ceases to lose weight, 12 parts (144 grains); Citric Acid 28 parts (336 grains); Alcohol 30 parts (360 grains or 1 fluidounce); Distilled Water a sufficient quantity; to make 200 parts (2400 grains or 5½ oz. av.). Dissolve the citrate of iron and ammonia in 200 parts (2400 grains or 5½ fluidounces) of distilled water, contained in a tared porcelain capsule, heat the solution to 60° C. (140° F.) on a water-bath, add the citric acid, and when it is dissolved add the quinine, stirring the mixture until a perfect solution has been obtained. Evaporate this to 160 parts (1920 grains or 4¾ oz. av.), allow it to cool, add the alcohol, and finally enough distilled water to make the whole weigh 200 parts (2400 grains or 5½ oz. av.)—*U. S.* The quantities indicated will yield a little over 4½ fluidounces.

The pharmacopœial citrate of iron and quinine is slowly and with some difficulty soluble in water, while the salt of the same name in the British Pharmacopœia is readily soluble in water, and was on that account preferred for use in mixtures. The solution which has now been adopted contains a salt closely analogous to the latter and a definite proportion of quinine; it is readily prepared with ordinary care. Starting with quinine sulphate, not less than 220 grains of this salt should be used for precipitating the alkaloid; the precautions to be observed are mentioned under QUININA; the yield will be about 10 per cent. more than is required for the quantity indicated above. The dried quinine does not dissolve as rapidly as the freshly-prepared hydrate, but the temperature during digestion should not be raised above 60° C. (140° F.), to prevent the reducing action of the citric acid upon the ferric compound; for the same reason the concentration of the liquid should be effected at the same temperature.

Properties.—This solution is “a dark greenish-yellow to yellowish-brown liquid, transparent in thin layers, odorless, having a bitter and mildly ferruginous taste and a slightly acid reaction. On supersaturating the diluted solution with a slight excess of ammonia the color of the liquid is deepened and a white, curdy precipitate is thrown down, which is soluble in ether and answers to the reaction of quinine. (See QUININA.) A small portion of the filtrate, when mixed with test solution of ferrocyanide of potassium, does not produce a blue color or precipitate unless it is acidulated with hydrochloric acid. If another portion of the filtrate be deprived of its iron by boiling with an excess of potassa, the concentrated and cooled filtrate precipitated by test solution of chloride of calcium, and the new filtrate heated to boiling, a white granular precipitate is produced. On heating the solution with potassa vapor of ammonia is evolved.”—*U. S.*

Tests.—The solution contains 6 per cent. of (anhydrous) quinine. It may be assayed as follows: Dilute 8 Gm. of the solution with water to 30 Ccm., introduce it, with any rinsings, into a glass separator, add an aqueous solution of 0.5 Gm. of tartaric acid, and then solution of soda in decided excess. Extract the alkaloid by agitating the mixture with four successive portions of chloroform, each of 15 Ccm. Separate the chloroformic layers, mix them, evaporate them in a weighed capsule on a water-bath, and dry the residue at a temperature of 100° C. (212° F.). It should weigh 0.48 Gm.—*U. S.* That the solution has not been prepared simply by dissolving quinine sulphate in the iron citrate is shown, aside from the different color, by its not yielding a precipitate with barium chloride after having been acidulated with hydrochloric acid. On evaporating the solution to dryness and igniting the residue an ash is left which has not an alkaline reaction upon test-paper (absence of fixed alkalies).

Off. Prep.—*Vinum ferri amarum*, *U. S.*

Medical Action and Uses.—A convenient and agreeable preparation of a medi-

cine very generally used in the form of bitter wine of iron. *Dose*, 10 to 15 minims (Gm. 0.60-1).

LIQUOR FERRI NITRATIS, U. S.—SOLUTION OF NITRATE OF IRON.

Liquor ferri pernitratis, Br.—*Solution of ferric nitrate, Solution of pernitrates of iron*, E.; *Azotate (Pernitrate) de fer liquide*, Fr.; *Eisennitrat-Lösung, Ferrinitrat-Lösung*, G.

An aqueous solution of ferric nitrate $\text{Fe}_2(\text{NO}_3)_6$; molecular weight 483.8—containing about 6 per cent. of the anhydrous salt.

Preparation.—Solution of Tersulphate of Iron 18 parts (9 oz. av. or $52\frac{1}{2}$ fluidrachms); Water of Ammonia 15 parts ($7\frac{1}{2}$ oz. av. or $7\frac{1}{2}$ fluidounces); Nitric Acid 7 parts ($3\frac{1}{2}$ oz. av. or 19 fluidrachms); Distilled Water, Water, each a sufficient quantity; to make 100 parts (50 oz. av.). To the water of ammonia previously diluted with 40 parts (20 oz. av. or $19\frac{1}{2}$ fluidounces) of cold water, add, constantly stirring, the solution of tersulphate of iron, previously diluted with 100 parts (50 oz. av. or 3 pints) of cold water. Pour the whole on a wet muslin strainer, allow the precipitate to drain, then return it to the vessel and mix it intimately with 100 parts (50 oz. av. or 3 pints) of cold water. Again drain it on a strainer, and repeat the operation until the washings cause but a very slight cloudiness with test solution of chloride of barium. Then allow the excess of water to drain off, place the precipitate in a capacious porcelain dish, and add the nitric acid, stirring till a clear solution is obtained. Finally, add sufficient distilled water to make the whole weigh 100 parts (50 oz. av. or $45\frac{3}{4}$ fluidounces).—*U. S.*

Take of fine iron wire, free from rust, 1 ounce; nitric acid $4\frac{1}{2}$ fluidounces; distilled water a sufficiency. Dilute the nitric acid with 16 ounces of the water, introduce the iron wire into the mixture, and leave them in contact until the metal is dissolved, taking care to moderate the action, should it become too violent, by the addition of a little more distilled water. Filter the solution, and add to it as much distilled water as will make its bulk $1\frac{1}{2}$ pints (30 fluidounces).—*Br.*

Both formulas aim at the production of ferric nitrate, Fe_26NO_3 . If the directions of the British Pharmacopœia are followed, the iron is taken up, with the evolution of red vapors, the reaction being as follows: $\text{Fe}_2 + 8\text{HNO}_3$ yields $\text{Fe}_26\text{NO}_3 + 2\text{NO} + 4\text{H}_2\text{O}$. Considerable heat is produced, and may rise to such a degree that nitric acid is vaporized; the reaction must therefore be closely watched, and, if it should become too violent, moderated by the addition of some cold water. This difficulty was sought to be avoided in the process of the U. S. P. 1870 by first forming ferrous nitrate and converting this into the ferric salt. Berzelius observed that, besides ferrous nitrate, ammonium nitrate is also formed and no gas evolved if a mixture of iron, water, and nitric acid is kept below the temperature of 50°C . (122°F .), when $2\text{Fe}_2 + 10\text{HNO}_3$ yields $4(\text{Fe}_2\text{NO}_3) + \text{NH}_4\text{NO}_3 + 3\text{H}_2\text{O}$. The formation of ammonia is a secondary reaction, and depends upon the action of the nascent hydrogen upon the excess of nitric acid; it is lessened, but not entirely prevented, by a stronger acid and at a higher temperature, and augmented as the temperature and the acid strength are decreased, sometimes to such a degree that considerable ferrous hydrate is separated. It follows from this that solutions thus prepared are apt to vary in their composition.

The present formula of the U. S. P. is essentially that of F. T. Bower (1876). Ferric hydrate is first prepared, and, after washing it well, is dissolved in the nitric acid. Care should be taken that the latter has the proper specific gravity; weaker acids will yield darker-colored basic compounds, some of which are insoluble or sparingly soluble in water.

Ordway (1865) found that weak solutions of *ferrous nitrate*, which are free from excess of acid, may be concentrated at 60°C . (140°F .), but must then be evaporated at a lower temperature to prevent oxidation. The green crystals obtained in the cold cannot be dried without decomposition. *Ferric nitrate* has been obtained in deliquescent colorless or purplish crystals, which are cubes when containing $12\text{H}_2\text{O}$, or prisms with $18\text{H}_2\text{O}$.

Properties.—The solution has a reddish-brown, or, if the acid is somewhat in excess, a pale-amber, color, which becomes darker on heating and lighter again on cooling. It is perfectly transparent, inodorous, has a strongly styptic taste and an acid reaction, and remains unaltered on exposure to light and air, except in the presence of organic compounds, by many of which it is deoxidized. It gives a red-brown precipitate with ammonia and other alkalis and alkali carbonates, and a dark-blue precipitate with potassium ferrocyanide. When mixed with a solution of ferrous sulphate, and then with

strong sulphuric acid, it assumes a blackish-brown color. The specific gravity is 1.050 *U. S. P.*, 1.107 *Br. P.*

Tests.—Ferricyanide of potassium, nitrate of silver, and nitrate of barium should not disturb the solution, proving the absence of ferrous salt, chloride, and sulphate. If precipitated with an excess of ammonia, the filtrate evaporated to dryness, and the salt heated to redness, no residue should be left (other metals). "10 Gm. of the solution, when precipitated by water of ammonia in excess, yield a precipitate which, when washed, dried, and ignited, should weigh 0.2 Gm."—*U. S.* The ferric oxide obtained from a fluidrachm of the solution by precipitating with ammonia, washing, and igniting, is required to weigh 2.6 grains.—*Br. P.*

Medical Action and Uses.—This preparation differs in its properties from the other acid compounds of iron. It is much more astringent than the vegetable acid salts or than the iodide of iron, and less harsh than the sulphuric and muriatic acid compounds. It is used chiefly in chronic *diarrhœa* dependent upon debility of the system or following dysentery, when no febrile complication exists. It is also profitably employed in *leucorrhœa* affecting feeble and lymphatic females, both internally and locally, and in *menorrhagia* occurring under similar conditions. The *dose* is about 10 drops (Gm. 0.60), largely diluted. As an injection, from 10 to 30 drops (Gm. 0.60–2) in a fluidounce of water may be employed.

LIQUOR FERRI SUBSULPHATIS, *U. S.*—SOLUTION OF SUBSULPHATE OF IRON.

Solution of basic ferric sulphate, Solution of persulphate of iron, Monsel's solution, E.: Liqueur hémostatique de Monsel, Fr.; Basisch-schwerfelsäure, Eisenoxydlösung, Monsel's Eisenzösung, G.

An aqueous solution of basic ferric sulphate, $\text{Fe}_2\text{O}(\text{SO}_4)_3$; molecular weight 719.6—containing 43.7 per cent. of the salt.

Preparation.—Sulphate of Iron 77 parts (7700 grains or 17½ oz. av.); Sulphuric Acid 7 parts (700 grains or 1½ oz. av.); Nitric Acid, Distilled Water, each a sufficient quantity; to make 114 parts (11400 grains or 26 oz. av. and 25 grains). Mix the sulphuric acid with 11 parts (1100 grains or 2½ oz. av.) of nitric acid and with 50 parts (5000 grains or 11½ oz. av., or 11 fluidounces) of distilled water in a capacious porcelain capsule, and, having heated the mixture to the boiling-point, add the sulphate of iron (one-fourth of it at a time), stirring after each addition until effervescence ceases. Should the addition of a few drops of nitric acid cause a further evolution of red fumes, cautiously add nitric acid until red fumes cease to be evolved. Then keep the solution in brisk ebullition until nitrous vapors are no longer perceptible and the liquid assumes a deep ruby-red tint. Lastly, add enough distilled water to make the solution weigh 114 parts (11400 grains or 26 oz. av. and 25 grains—16 fluidounces and 45 minims.). Solution of subsulphate of iron is to be dispensed when solution of persulphate of iron is prescribed by the physician.—*U. S.*

This process is a slight modification of that proposed by Dr. Squibb (1860). On introducing the ferrous sulphate in small portions into the heated acids a black color is produced from the union of nitric oxide with ferrous sulphate, which disappears with the copious evolution of red nitrous vapors as fast as the sulphate dissolves in the hot liquid. The mixture foams most toward the end of the process, and after the liquid has again subsided a little of it should be tested with nitric acid to ensure its complete oxidation. The amount of sulphuric acid used is insufficient for forming the normal ferric sulphate. A basic or oxysulphate is the result, which has the composition $\text{Fe}_2\text{O}(\text{SO}_4)_3 + aq$ or $5(\text{Fe}_2\text{SO}_4) \cdot \text{Fe}_2\text{HIO}$. The mineral *copiapite* is a crystallized hydrate of the same combination. Other more basic ferric sulphates are known, some being soluble, others insoluble in water.

Properties.—Monsel's solution is a deep red-brown liquid, being nearly of a syrupy consistence, and of the spec. grav. 1.555. It is almost inodorous, has a very astringent but not caustic taste, and an acid reaction, and mixes with water and alcohol in all proportions without decomposition. On dropping sulphuric acid into it the color becomes lighter, and with a larger quantity (½ volume) of the acid a separation of whitish anhydrous ferric sulphate takes place (difference from solution of tersulphate). Diluted with distilled water, it yields a red-brown precipitate with ammonia or potassa, a dark-blue one with potassium ferrocyanide, and a white one insoluble in nitric or hydrochloric acid with barium chloride. When evaporated at a moderate heat upon a glass or porcelain plate, it

yields transparent, deliquescent scales, and at a somewhat higher temperature is converted into a yellowish powder which is less deliquescent.

Tests.—The solution, diluted with 5 parts of water, should be colored olive-brown, but not blue, with freshly-prepared solution of potassium ferrieyanide, and it should not yield a white precipitate with silver nitrate (absence of ferrous salt and chloride). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the solution, the crystal should not become brown, nor should there be a brownish-black zone developed around it (absence of nitric acid). "10 Gm. of the solution, when completely precipitated by excess of water of ammonia, yield a precipitate which, when washed, dried, and ignited, should weigh 1.938 Gm."—*U. S.* The filtrate obtained in applying this test, on being evaporated to dryness and then ignited, should leave no fixed residue (absence of other salts).

Medical Uses.—This preparation is chiefly used as a local styptic in cases of *hæmorrhage* from parts not readily subjected to pressure, as the nasal cavities, the sockets from which teeth have been extracted, the uterus, vagina, rectum, etc. It has the advantage of being less irritating than other acid salts of iron. It is generally applied by means of a wooden or glass brush or a fragment of compact sponge. Where pressure can also be made it should not be omitted. An atomized solution of it has been found successful in some cases of *hæmoptysis*. For this purpose from 1 to 10 minims (Gm. 0.06–0.60) should be dissolved in a fluidounce of distilled water. Internally, it may be prescribed in the dose of from 5 to 10 minims (Gm. 0.30–60), properly diluted.

LIQUOR FERRI TERSULPHATIS, *U. S.*—SOLUTION OF TERSULPHATE OF IRON.

Liquor ferri persulphatis, Br.; *Liquor ferri sulfurici oxydati*, P. G.—*Solution of normal ferric sulphate*, *Solution of persulphate of iron*, E.; *Persulfate de fer liquide*, Fr.; *Ferri-sulfatlösung*, *Schwefelsaure Eisenoxyd-Lösung*, G.

An aqueous solution of normal ferric sulphate, $\text{Fe}_2(\text{SO}_4)_3$; molecular weight 399.8—containing 28.7 per cent. of the salt.

Preparation.—Sulphate of Iron 80 parts (8 oz. av.); Sulphuric Acid 15 parts (1½ oz. av.); Nitric Acid, Distilled Water, each a sufficient quantity; to make 200 parts (20 oz. av.). Mix the sulphuric acid with 11 parts (1 oz. av. and 45 grains) of nitric acid and with 50 parts (5 oz. av. or 4½ fluidounces) of distilled water in a capacious porcelain capsule, and, having heated the mixture to the boiling-point, add the sulphate of iron (one-fourth of it at a time), stirring, after each addition, until effervescence ceases. Should the addition of a few drops of nitric acid cause a further evolution of red fumes, cautiously add nitric acid until red fumes cease to be evolved. Then continue the heat until the solution acquires a reddish-brown color and is free from nitrous odor. Lastly, add enough distilled water to make the whole weigh 200 parts (20 oz. av. = 14½ fluidounces).—*U. S.*

Take of sulphate of iron 8 ounces; sulphuric acid, nitric acid, each 6 fluidrachms; distilled water 12 fluidounces or a sufficiency. Add the sulphuric acid to 10 ounces of the water, and dissolve the sulphate of iron in the mixture with the aid of heat. Mix the nitric acid with the remaining 2 ounces of the water, and add to this acid, warmed, the solution of sulphate of iron. Concentrate the whole by boiling, until, by the sudden disengagement of ruddy vapors, the liquid ceases to be black and acquires a red color. A drop of the solution is now to be tested with red prussiate of potash, and if a blue precipitate forms, a few additional drops of nitric acid should be added and the boiling renewed, in order that the whole of the sulphate may be converted into persulphate of iron. When the solution is cold, make the quantity 11 fluidounces (Imperial measure) by the addition, if necessary, of distilled water.—*Br.*

The reaction which takes place in these processes is precisely the same as in making the subsulphate of iron, the only difference being that the sulphuric acid is used in sufficient quantity to form normal ferric sulphate, Fe_2SO_4 . The reaction is explained by the equation $6\text{FeSO}_4 + 3\text{H}_2\text{SO}_4 + 2\text{HNO}_3 = 3(\text{Fe}_2\text{SO}_4) + \text{N}_2\text{O}_2 + 4\text{H}_2\text{O}$. From 80 parts of ferrous sulphate, 200 parts *U. S.*, 160 parts *P. G.*, 158.5 parts *Br.*, of the solution are prepared.

Properties.—Solution of normal ferric sulphate is a dark reddish-brown liquid, having no odor, a very astringent and at the same time acid taste, and an acid reaction. It is miscible in all proportions with alcohol and water without causing decomposition. Its behavior to ammonia, potassium ferrocyanide, and barium chloride is the same as that

of the subsulphate, but for the precipitation of the anhydrous salt about 3 volumes (instead of $\frac{1}{2}$ volume) of sulphuric acid is required. The pharmacopœial solution contains 28.76 per cent. *U. S.*, 35.94 per cent. *P. G.*, 36.3 per cent. *Br.* of anhydrous ferric sulphate, and has the spec. grav. 1.320 *U. S.*, 1.428 to 1.430 *P. G.*, 1.441 *Br.* Hager gives the following densities for solutions containing of the anhydrous salt—

25	26	27	28	28.5	29	29.5	30	31	32 per cent.
1.271	1.284	1.297	1.310	1.316	1.323	1.330	1.337	1.351	1.365.

Tests.—The absence of ferrous salt, chloride, nitric acid, and foreign salts is determined in precisely the same manner as for the subsulphate (see above). The German Pharmacopœia requires the solution to contain a minute amount of basic salt, which is determined by adding 3 drops of the solution to 10 Ccm. of volumetric solution of sodium hyposulphite, and heating the mixture very slowly to the boiling-point, when a few floccules of ferric oxide should be separated; the ferric hyposulphite which is at first formed changes into ferrous hyposulphite, FeS_2O_6 , and ferrous tetrathionate, FeS_4O_6 ; and no further change takes place on careful heating if only normal sulphate was present, but in the presence of oxysulphate ferric oxide is deposited, while in the presence of free acid sulphurous acid gas is liberated and sulphur is separated, causing a whitish turbidity. The same test may also be applied to the solution of ferric chloride, the results being the same as described. “10 Gm. of the solution, when completely precipitated by excess of water of ammonia, yield a precipitate which, when washed, dried, and ignited, should weigh 1.147 Gm.”—*U. S.* 1 fluidrachm of the solution, diluted with water and mixed with an excess of ammonia-water, should yield a precipitate which, when washed and ignited, weighs 11.44 grains.—*Br.*

Pharmaceutical Uses.—In preparing magnetic oxide of iron and ferric oxide as an antidote to arsenic, or for preparing the solutions of acetate, citrate, and nitrate of iron, and various tartrates and citrates containing iron; also in preparing, by double decomposition, Tinct. ferri acetatis, *Br.*, and in forming the double salt Ferri et ammonii sulphas, *U. S.*

Medical Uses.—It may be used for the same purpose as the subsulphate, but is not as eligible, because it is more irritating and less astringent.

LIQUOR GUTTA-PERCHÆ, *U. S.*, *Br.*—SOLUTION OF GUTTA-PERCHA.

Liquor de gutta-percha, Fr.; Guttapercha-Lösung, Traumaticin, G.

Preparation.—Gutta-Percha, in thin slices, 9 parts (1 oz. av.); Commercial Chloroform 91 parts (10 oz. av. and 50 grains); Carbonate of Lead, in fine powder, 10 parts (1 oz. av. and 50 grains); to make 100 parts (11 oz. av.). Add the gutta-percha to 70 parts (8 oz. av.) of the chloroform contained in a bottle, cork the latter well, and shake it occasionally until the gutta-percha is dissolved. Then add the carbonate of lead, previously mixed with the remainder of the chloroform, and, having several times shaken the whole together at intervals of half an hour, set the mixture aside until the insoluble matters have subsided and the solution has become perfectly clear. Lastly, decant the liquid and preserve it in small, cork-stoppered vials.

The British Pharmacopœia has the same process, but directs 1 oz. av. of gutta-percha and 8 fluidounces (11.92 oz. av.) of chloroform, or for 9 parts of the former 107.2 parts of the latter. The proportion directed by the *U. S. P.* 1870 was 9 to 102 parts; the present Pharmacopœia requires only 91 parts of chloroform, which, if the gutta-percha be of good quality, gives a rather thick solution. This preparation has been sometimes called *chloro-percha*.

Crude gutta-percha does not yield a clear solution with chloroform, but on standing the impurities will rise to the surface more rapidly if, according to Maschke (1857), the solution is agitated with 1 or $1\frac{1}{2}$ per cent. of water. Hodgson (1861) proposed carbonate of lead with the same object in view, the impurities subsiding with the lead compound. Other heavy and insoluble compounds may be used with the same result, of rendering the solution clear and almost or entirely colorless. Other solvents, which are cheaper than chloroform, are employed for the purification of gutta-percha on the large scale (see page 754).

Off. Prep.—Charta sinapis, *U. S.*, *Br.*

Medical Uses.—The various applications of this solution are enumerated under GUTTA-PERCHA. They consist, briefly, in the adhesive and protective qualities of the

film formed by the rapid evaporation of the solvent, and the facility with which the solution is applied.

LIQUOR HYDRARGYRI NITRATIS, U. S.—SOLUTION OF NITRATE OF MERCURY.

Liquor hydrargyri nitratis acidus, Br.; *Liquor hydrargyri nitrici oxydati*, *Hydrargyrum oxydatum nitricum solutum*.—Solution of mercuric nitrate, Acid solution of nitrate of mercury. Solution of pernitate of mercury, E.; Azotate (Nitrate) mercurique liquide, Nitrate acide (Pernitrate) de mercure, Fr.; Mercurinitrat-Lösung, Quecksilberoxydnitrat-Lösung, G.

A liquid containing in solution about 50 per cent. of mercuric nitrate, $\text{Hg}(\text{NO}_3)_2$; molecular weight 327.7, with some free nitric acid.

Preparation.—Red Oxide of Mercury 40 parts (8 oz. av.); Nitric Acid 45 parts (9 oz. av. or 3 fluidounces and 45 minims); Distilled Water 15 parts (3 oz. av. or $2\frac{1}{2}$ fluidounces); to make 100 parts (20 oz. av. or 9 fluidounces and 68 minims). Mix the nitric acid with the distilled water, and dissolve the red oxide of mercury in the mixture. Keep the solution in glass-stoppered bottles.—U. S.

Take of mercury 4 ounces; nitric acid 5 fluidounces; distilled water $1\frac{1}{2}$ fluidounces. Mix the nitric acid with water in a flask, and dissolve the mercury in the mixture without the application of heat. Boil gently for 15 minutes, cool, and preserve the solution in a stoppered bottle.—Br.

Mercury 100 parts; nitric acid 150 parts; water 50 parts. Dissolve and evaporate to 225 parts.—F. Cod.

The mercury is dissolved in the two last processes by the action of nitric acid, with the extrication of red nitrous vapors to form mercuric nitrate; $3\text{Hg}_2 + 16\text{HNO}_3$ yields $6(\text{Hg}_2\text{NO}_3) + 2\text{N}_2\text{O}_2 + 8\text{H}_2\text{O}$. It is necessary to apply some heat, particularly at the close of the reaction, to convert into mercuric any mercurous salt which may be present. The United States process yields the same solution more rapidly, and involves simply a combination of the mercuric oxide with nitric acid, water being liberated; $\text{HgO} + 2\text{HNO}_3$ yields $\text{Hg}(\text{NO}_3)_2 + \text{H}_2\text{O}$. The present pharmacopœial solution is a little weaker than that of 1870, the latter requiring 43.66 parts of mercuric oxide and 48.66 parts of nitric acid to obtain 100 parts; it was nearly identical with that of the French Codex, which represents 43.5 per cent. of mercuric oxide against about 35 per cent. of the British preparation.

Properties.—The solution is colorless, and has a slight odor of nitric acid, a strong acid reaction, and a caustic and metallic taste. Its specific gravity is 2.100 U. S. P., about 2.0 Br. A crystal of ferrous sulphate dropped into it soon becomes surrounded with a dark-colored liquid (nitrate). Dropped upon copper, a deposit of mercury is at once produced, and the diluted solution gives a yellow precipitate with soda or potassa solution and a scarlet-red precipitate with potassium iodide; this latter precipitate is soluble in an excess of the precipitant. Nearly one-fourth of the nitric acid is uncombined, and prevents the separation of a basic salt on dilution with water. Evaporated by heat on a glass or porcelain dish, a white salt is left, which on the further application of heat is decomposed, assuming a yellow, red, and brown color, and is finally completely volatilized. The solution, mixed with alcohol and heated, produces *fulminating mercury*, which is very explosive.

If the solution is kept over sulphuric acid until crystals have been separated, the syrupy liquid will have the composition $\text{Hg}_2\text{NO}_3 \cdot 2\text{H}_2\text{O}$, and the crystals of mercuric nitrate contain less water, their composition being $2(\text{Hg}_2\text{NO}_3) \cdot \text{H}_2\text{O}$. If the liquid is further concentrated by heat, nitric acid is given off, and the solution contains then basic nitrates, which are crystallizable, but when largely diluted with water are converted into more basic insoluble white or yellowish compounds.

Tests.—The characters given are sufficient to determine the quality of the preparation. On the addition of water no precipitation should occur (free nitric acid). Diluted hydrochloric acid should occasion no precipitate, potassa solution a yellow (not black), and potassium iodide a scarlet-red (not yellow or green) precipitate (absence of mercurous salt).

Allied Preparations.—MILLON'S TEST SOLUTION. Dissolve with a gentle heat mercury in an equal weight of strong nitric acid, dilute the solution with twice its bulk of water, and decant from the precipitate; the liquid must contain some free nitric and nitrous acid. A solution of nearly the same mercury strength, but containing no nitrous acid, is obtained by diluting the pharmacopœial (U. S.) solution of mercuric nitrate with an equal bulk of water. Millon's

reagent is used as a reagent for proteids, the mixture, as well as the precipitate, acquiring a red color on boiling.

HYDRARGYRI PROTONITRAS; Nitras (azotas) hydrargyrosus, *F. Cod.*—Mercurous nitrate, *E.*; Azotate mercurieux, *Fr.*; Mercuronitrat, Salpetersaures Quecksilberoxydul, *G.*—Mercury 4 parts, nitric acid 3 parts, water 1 part; after 24 hours collect the crystals, wash them with a little diluted nitric acid, and dry.—*F. Cod.* The salt forms colorless monoclinic plates or prisms having the composition $Hg_2(NO_3)_2 \cdot 2H_2O$, mol. weight 559.4; it melts at $70^\circ C.$ ($158^\circ F.$), is completely soluble in a little warm water, but is by more water decomposed into a soluble acid and an insoluble basic salt; the solution imparts to the skin a purplish-red color, turning black.

LIQUOR HYDRARGYRI NITRICI OXYDULATI, s. Hydrargyrum oxydulatum solutum, s. Liquor Bellostii.—Solution of mercurous nitrate, *E.*; Liqueur de Bellosté, *Fr.*; Mercuronitrat-Lösung, *G.*—Dissolve without heat mercurous nitrate 100 parts in nitric acid 15 parts and water 885 parts. On exposure to the air oxidation to mercuric nitrate takes place.

Medical Action and Uses.—It is not used internally. Locally, its action is powerfully caustic, destroying the life of the tissue to which it is directly applied and inflaming the surrounding parts. The slough separates as a yellowish scab. When swallowed by mistake, it produces the effects of a powerful corrosive poison, including intense pain, vomiting, purging, collapse, and speedy death, after which the fauces have been found vesicated and discolored and the stomach presenting brown eschars. Applied to an ulcerated surface, even of small extent, it has caused salivation, and a weak solution of it used in the treatment of itch has occasioned fatal poisoning, with symptoms of corrosion and salivation also.

This preparation is employed to stimulate sluggish restorative processes and to remove indurated tissues. It is a valuable application in chronic and indurated *ulcers* of the neck of the uterus of whatever nature, but most so, of course, in simple ulcers. Tubercles and ulcers of the skin belonging to *lupus* have sometimes been treated advantageously by this caustic while appropriate internal medicines were administered. It is advised that it should be applied daily. It is an efficient remedy for *acne* by destroying the diseased sebaceous follicles. It has been recommended as the most successful of local applications to all forms of *syphilitic* sores of the skin, tongue, throat, etc. The strength of the solution employed must vary with the object in view. In *lupus* and *acne* the pure liquid must be used, and applied by means of a pointed glass rod or brush or a wooden splinter, so as accurately to limit the caustic action to the diseased tissue. When ulcers of the throat are to be treated, 1 or 2 minims of the acid in an ounce of water (Gm. 0.06–0.12 to Gm. 32) may be used as a gargle or with an atomizer, care being taken that the spray is not inhaled; or by means of a sponge-mop a mixture of a fluidrachm of the solution with an ounce of water (Gm. 4 to Gm. 32) may be applied. For cutaneous ulcers a lotion may be made with 30 minims of the solution and an ounce (Gm. 2 to Gm. 32) of water.

LIQUOR HYDRARGYRI PERCHLORIDI, *Br.*—SOLUTION OF PERCHLORIDE OF MERCURY.

Liquor hydrargyri bichloridi.—Solution of corrosive sublimate, Solution of mercuric chloride, *E.*; Chlorure de mercure et d'ammoniaque liquide, Soluté de sel Alembroth, *Fr.*; Sublimat-Lösung, *G.*

Preparation.—Take of Perchloride of Mercury. Chloride of Ammonium, each 10 grains; Distilled Water 1 pint (Imperial). Dissolve.—*Br.*

This is a colorless solution of the *sal Alembroth* of the alchymists, having the saline and metallic taste of the salts from which it is made. It yields white precipitates with alkalis and their carbonates, and is decomposed by vegetable juices and the medicinal extracts. It contains $\frac{1}{2}$ grain of corrosive sublimate to the (Imperial) fluidounce, and is of one-half the strength of the similar solution which was formerly recognized by the Prussian and other European pharmacopœias. By substituting emulsion of bitter almond for the water *Goulard's cosmetic lotion* is obtained.

LIQUEUR DE VAN SWIETEN, *F. Cod.*, is a solution of 1 part of corrosive sublimate in 100 parts of alcohol and 900 parts of water.

Medical Action and Uses.—The object of this preparation appears to be to render the solution of corrosive sublimate more perfect than that in water alone. The average *dose* is 1 fluidrachm (Gm. 4), containing $\frac{1}{16}$ grain (Gm. 0.004) of corrosive sublimate.

LIQUOR IODI COMPOSITUS, U. S.—COMPOUND SOLUTION OF IODINE.

Liquor iodi, Br.; *Liquor iodinii compositus*, U. S. 1870.—*Solution of iodine*, *Lugol's solution*, E.; *Soluté ioduré de Lugol*, Fr.; *Lugol'sche Jodlösung*, G.

Preparation.—Iodine 5 parts (107 grains); Iodide of Potassium 10 parts (214 grains); Distilled Water 85 parts (1819 grains or 4 fluidounces); to make 100 parts (2140 grains or about 4½ fluidounces). Dissolve the iodine and iodide of potassium in the distilled water. Keep the solution in well-stopped bottles.—*U. S.*

Take of iodine 22 grains; iodide of potassium 33 grains; distilled water 1 fluidounce. Dissolve.—*Br.*

Solutions of potassium iodide dissolve iodine in different proportions, weak solutions taking up 1 atom of I for each molecule of KI, or 76.5 parts for 100 parts of the salt. The dissolved portion, therefore, has the composition KI₂. The proportion of iodine to potassium iodide in the second formula approaches the composition given, but the formula of the United States Pharmacopeia directs a larger amount of the salt and its iodine strength is greater. Viewed as free iodine held in solution by potassium iodide, 1 part of the former is represented by 20.0 parts (*U. S. P.*) and 22.4 parts (*B. P.*) of the solution.

Properties.—The solution is of a dark brown-red color, having the caustic taste of iodine and imparting to starch-paste a dark-blue color. When boiled, iodine is given off, but the whole of it does not volatilize until the liquid is evaporated to dryness and the residuary mass heated nearly to redness. When agitated with chloroform, ether, or bisulphide of carbon, the solution is decolorized. “12.66 Gm. of the solution, mixed with a little gelatinized starch, should require for complete decoloration 50 Ccm. of the volumetric solution of hyposulphite of sodium.”—*U. S.*

Allied Preparations.—CAUSTICUM IODI, *Lugol's caustic*. Iodine and potassium iodide, of each 1 part, water 2 parts. By substituting glycerin for the water *Hebra's iodine caustic* is obtained.

Medical Action and Uses.—This preparation is considerably stronger in the proportion of its active ingredients than the compound *tincture* of iodine, and is thought to be more efficient, although there is no satisfactory evidence in favor of that opinion. 20 minims (Gm. 1.15) of it contain about 1 grain (Gm. 0.06) of iodine. The average *dose* is 4 drops (Gm. 0.25). It should be administered in a large portion of water.

LIQUOR LITHIÆ EFFERVESCENS, Br.—EFFERVESCING SOLUTION OF LITHIA.

Aqua lithiæ effervescens.—*Lithia-water*, E.; *Eau de lithine*, Fr.; *Lithion-wasser*, G.

Preparation.—Take of Carbonate of Lithia 10 grains; Water 1 pint. Mix in a suitable apparatus, and pass into it as much pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk, as can be introduced with a pressure of seven atmospheres. Keep the solution in bottles securely closed to prevent the escape of the compressed gas.—*Br.*

This is a solution of lithium carbonate in water rendered more agreeable by the carbonic acid gas. Each fluidounce contains ½ grain of the carbonate, the amount of which is best ascertained by evaporating a known measure of it. The residue should answer to the tests for lithium carbonate.

Medical Uses.—This is merely an agreeable form for the administration of lithia; it may be given in the *dose* of from 4 to 12 fluidounces (Gm. 120–380).

LIQUOR MAGNESII CARBONATIS, Br.—SOLUTION OF CARBONATE OF MAGNESIUM.

Aqua magnesio-effervescens.—*Fluid magnesia*, E.; *Eau magnésienne*, *Magnésie liquide*, Fr.; *Magnesiawasser*, *Kohlensaure MagnesiaLösung*, G.

Preparation.—Take of Sulphate of Magnesia 2 ounces; Carbonate of Soda 2½ ounces; Distilled Water a sufficiency. Dissolve the two salts separately, each in ½ pint of water. Heat the solution of sulphate of magnesia to the boiling-point, then add to it the solution of carbonate of soda, and boil them together until carbonic acid ceases to be evolved. Collect the precipitated carbonate of magnesia on a calico filter, and wash it with distilled water until what passes ceases to give a precipitate with chloride of barium. Mix the washed precipitate with a pint of distilled water, and, putting them into a suit-

able apparatus, pass into it pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk. Let the mixture remain in contact with excess of carbonic acid, retained there under pressure, for about 24 hours; then filter the liquid to remove any undissolved carbonate of magnesia, and again pass carbonic acid gas into the filtered solution. Finally, keep the solution in a bottle securely closed to prevent the escape of carbonic acid. The solution contains about 13 grains of carbonate of magnesia in a fluidounce.—*Br.*

The first part of the above process embraces the preparation of magnesium oxycarbonate, $(\text{MgCO}_3)_3 \cdot \text{Mg}_2\text{HO}$, which is the officinal *Magnesii carbonas*. By the subsequent operation this is dissolved in water by the aid of carbonic acid gas in excess, whereby magnesium carbonate, MgCO_3 , and bicarbonate, MgH_2CO_3 , are formed.

Properties and Tests.—It is a colorless solution, which should effervesce on opening the vessel, carbonic acid escaping, and has a slightly acidulous taste free from bitterness. The white mass left by evaporating a fluidounce and calcining the residue should weigh 5 grains and answer to the tests for magnesia. When the solution is exposed to cold, prismatic crystals of magnesium carbonate, $\text{MgCO}_3 \cdot 5\text{H}_2\text{O}$, appear, which on exposure to the air lose water and become $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$.

Medical Uses.—The intention of this preparation is apparently to provide an agreeable form of magnesia for administration in cases of constitutional *gout* and other disorders attended with an excess of *acid* in the system and acid urinary deposits. An extemporaneous mixture of magnesia with carbonated water answers the same purpose, and so do the granular effervescing vegetable salts of magnesia. The *dose* is 1 or 2 fluidounces (Gm. 32–64).

LIQUOR MAGNESII CITRATIS, U. S., *Br.*—SOLUTION OF CITRATE OF MAGNESIUM.

Liquor magnesie citratis, *Br. Add.*; *Liquor magnesii citrici*.—*Limnade au citrate de magnesie*, *Limnade purgative citra-magnésienne* *Fr.*; *Magnesiumcitrat-Lösung*, *Magnesia-Limnade*, *G.*

Preparation.—Carbonate of Magnesium 200 grains (13 Gm.); Citric Acid 400 grains (26 Gm.); Syrup of Citric Acid 1200 grains (80 Gm. or 2 fluidounces); Bicarbonate of Potassium, in crystals, 30 grains (2 Gm.); Water a sufficient quantity. Dissolve the citric acid in 2000 grains (4½ fluidounces) or about 120 Gm. of water, and, having added the carbonate of magnesium, stir until it is dissolved. Filter the solution into a strong bottle of the capacity of 12 fluidounces, or about 360 Ccm., containing the syrup of citric acid. Then add enough water, previously boiled and filtered, to nearly fill the bottle, drop in the bicarbonate of potassium, and immediately close the bottle with a cork, which must be secured with twine. Lastly, shake the mixture occasionally until the bicarbonate of potassium is dissolved.—*U. S.*

Take of carbonate of magnesia 100 grains; citric acid 200 grains; syrup of lemon ½ fluidounce; bicarbonate of potash, in crystals, 40 grains; water a sufficiency. Dissolve the citric acid in 2 ounces of the water, and, having added the carbonate of magnesia, stir until it is dissolved. Filter the solution into a strong half-pint bottle, add the syrup and sufficient water to nearly fill the bottle; then introduce the bicarbonate of potash, and immediately close the bottle with the cork, which should be secured with string or wire. Afterward shake the bottle until the bicarbonate of potash has dissolved.—*Br.*

When magnesium carbonate and citric acid are brought together in the presence of water carbonic acid gas is given off and magnesium citrate formed. The normal salt has the composition $\text{Mg}_2\text{C}_6\text{H}_5\text{O}_7$, is but slightly soluble in water, and crystallizes from its solutions with $14\text{H}_2\text{O}$. The salt, $\text{MgHC}_6\text{H}_5\text{O}_7$, is much more soluble in water, and it is this compound at which both pharmacopœias aim in the above formulas. The reaction occurs as follows: $(\text{MgCO}_3)_3 \cdot \text{Mg}_2\text{HO} - 4\text{H}_2\text{C}_6\text{H}_5\text{O}_7$, yields $4\text{MgHC}_6\text{H}_5\text{O}_7 - 3\text{CO}_2 - 5\text{H}_2\text{O}$. A slight excess of citric acid is employed, which is subsequently neutralized with potassium bicarbonate, whereby some potassium citrate is formed and carbonic acid gas liberated, the latter remaining with the hermetically-corked solution. Carbonate of magnesium, as ordinarily met with, varies much less in composition than calcined magnesia after some exposure to the atmosphere; the former compound is therefore very properly used in preference to the latter.

To prepare the solution, ten times (or any other convenient multiple) of the officinal quantities of citric acid and magnesium carbonate are weighed out and mixed with the corresponding quantity of water; after the magnesia has dissolved the liquid is passed

through a paper filter, equally divided among the requisite number of bottles, into each of which the necessary quantity of syrup is introduced; sufficient water, previously boiled and filtered, is then added to each bottle, after which the potassium bicarbonate in crystals is dropped in. The corks are then inserted and securely fastened by twine, and the bottles laid upon their sides in a cool place. Prepared in this way, the crystals will gradually dissolve in the syrup, and this will slowly mix with the lighter saline solution, unless it be wanted for immediate use, when, by slight agitation, the syrup and bicarbonate are dissolved in the aqueous liquid.

The solution is colorless, free from sediment, and of a pleasant acidulous taste free from bitterness. The present formula differs from that of 1870 only in ordering 30 instead of 40 grains of potassium bicarbonate; the latter quantity makes a more effervescent solution.

Allied Preparations.—LIQUOR MAGNESII ACETATIS.—Solution of magnesium acetate, *E.*: Soluté d'acétate de magnésie, *Fr.*: Magnesiumacetat-Lösung, *G.*—Renaud proposed a solution made by dissolving 40 parts of magnesium carbonate in sufficient acetic acid (137 parts), filtering, and evaporating to 100 parts. It is a colorless syrupy liquid, having a bitterish taste less pleasant than the citrate, and containing nearly 60 per cent. of the dry acetate, $Mg(C_2H_3O_2)_2$ (mol. weight 142). The dry salt is white, gum-like, very deliquescent, and freely soluble in water and alcohol.

ELIXIR MAGNESII ACETATIS. Solution of magnesium acetate 66 parts; alcohol 14 parts; syrup of orange-peel (or of lemon-peel) 70 parts. This contains 25 per cent. of the dry salt, but less alcohol than directed by Garot's formula.

Medical Action and Uses.—This medicine has come into popular use as a purgative, and, if its constitution could be depended upon, would answer a useful purpose. But as it sometimes purges violently, and in other cases fails of any purgative effect, it ought not to be employed where certainty and uniformity of action are important. It should generally be given in divided doses of 4 or 6 ounces (Gm. 120–190) every hour until the desired operation is produced.

Acetate of magnesium was introduced as a substitute for citrate of magnesium, probably on account of its greater cheapness, it being assumed to possess the same mode of action as the citrate. A committee of the Pharmaceutical Society of Paris reported it to be a purgative whose slight taste and great solubility recommended it. It is, however, less soluble than the citrate and of a less agreeable taste. It does not seem to have been approved by physicians.

LIQUOR MORPHINÆ ACETATIS, *Br.*—SOLUTION OF ACETATE OF MORPHINE.

Soluté d'acétate de morphine, Fr.; *Essigsäure Morphinlösung, G.*

Preparation.—Take of Acetate of Morphine 9 grains; Diluted Acetic Acid 18 minims; Rectified Spirit $\frac{1}{2}$ fluidounce; Distilled Water $1\frac{1}{2}$ fluidounces. Mix the acid, the spirit, and the water, and dissolve the acetate of morphine in the mixture.—*Br.*

Medical Uses.—Each fluidrachm contains $\frac{1}{2}$ grain (Gm. 4 and Gm. 0.03) of acetate of morphine, the decomposition of which is prevented by the spirit.

LIQUOR MORPHINÆ HYDROCHLORATIS, *Br.*—SOLUTION OF HYDROCHLORATE OF MORPHINE.

Soluté de hydrochlorate de morphine, Fr.; *Sälsäure Morphinlösung, G.*

Preparation.—Take of Hydrochlorate of Morphine 9 grains; Diluted Hydrochloric Acid 18 minims; Rectified Spirit $\frac{1}{2}$ fluidounce; Distilled Water $1\frac{1}{2}$ fluidounces. Mix the hydrochloric acid, the spirit, and the water, and dissolve the hydrochlorate of morphine in the mixture.—*Br.*

This and the preceding solution are about four times the morphine strength of the *Liquor morphinæ sulphatis* (*U. S. P.* 1870), which was made by dissolving 1 grain of morphine sulphate in 1 fluidounce of water. (For *Liq. morph. bimecon.* see p. 1109.)

In some parts of the United States a much stronger solution is prescribed under the name of *Magendie's solution of morphine*. It is prepared by dissolving 16 grains of sulphate of morphine in 1 fluidounce of water, and is therefore sixteen times stronger than the preceding. *Magendie's solution* is prepared in France by dissolving 0.8 Gm. (12 $\frac{1}{2}$ grains) of morphine acetate in 30 Gm. (1 fluidounce) of water, and is therefore considerably weaker than the solution known by the same name in the United States.

Medical Uses.—Each fluidrachm (Gm. 4) of this solution contains $\frac{1}{2}$ grain (Gm.

0.03) of muriate of morphine, and its *dose* is from 10 to 60 minims (Gm. 0.60–4.) It will be observed that it contains $\frac{1}{4}$ grains of the morphine salt to the ounce of water, while the solution of sulphate of morphine (*U. S. P.* 1870) contains but 1 grain to the fluidounce. Trousseau recommended, for hypodermic injection, a solution of muriate of morphine in glycerin, which preserves the salt from decomposition.

LIQUOR PEPSINI, *U. S.*—SOLUTION OF PEPSIN.

Liquid pepsin, E.; Pepsine liquide, Fr.; Pepsinlösung, G.

Preparation.—Saccharated Pepsin 40 parts (400 grains); Hydrochloric Acid 12 parts (120 grains); Glycerin 400 parts (4000 grains or 9 $\frac{1}{2}$ oz. av.); Water 548 parts (5480 grains or 12 $\frac{1}{2}$ oz. av. = 12 fluidounces); to make 1000 parts (10,000 grains or 22 $\frac{3}{4}$ oz. av.). Dissolve the saccharated pepsin in the water, previously mixed with the hydrochloric acid. After solution add the glycerin, let the mixture stand 24 hours, and filter.—*U. S.*

The solvent action of pepsin upon proteids being materially lessened through the presence of alcohol, Prof. E. Scheffer (1870) proposed to discard the wine of pepsin and similar alcoholic preparations in favor of an aqueous solution prepared by acting upon the mucous membrane of the hog's stomach and preserved by glycerin. Subsequently, in 1871, he employed saccharated pepsin, and this formula has been adopted with very slight modification. Sellden (1873) prefers dissolving the freshly-precipitated pepsin in glycerin.

Properties.—Solution of pepsin is a colorless or pale-yellowish liquid, transparent, of a very slight odor, and of a pleasant acidulous and sweet taste. When made directly from the mucous membrane it becomes mouldy on keeping and acquires an unpleasant fetid odor. These objectionable features are avoided by the use of properly-prepared saccharated pepsin. (See also PEPSINUM.)

Medical Uses.—The advantage of this preparation over pepsin that is merely mixed with powdered sugar of milk (*Pepsinum saccharatum*) is, that it is rendered more active by the hydrochloric acid it contains, and more permanent by the glycerin in which it is partly dissolved. In a fresh state it is probably as efficient as pepsin itself in preventing the fermentation of food in the stomach and the flatulence which results, with all their consequences. The *dose* for a child is 2 or 3 fluidrachms (Gm. 8–12), and for an adult from half a fluidounce to a fluidounce (Gm. 16–32).

LIQUOR PLUMBI SUBACETATIS, *U. S., Br.*—SOLUTION OF SUBACETATE OF LEAD.

Liquor plumbi subacetici, P. G.; Acetum plumbicum, Acetum saturni, Plumbum hydrico-aceticum solum, Subacetas plumbicus liquidus.—Goulard's extract, *E.*; Sous-acétate de plomb liquide, *E.*; Extrait de saturne (de Goulard), *Vinaigre de plomb (de saturne), Fr.; Bleissig, G.*

An aqueous liquid containing in solution about 25 per cent. of subacetate of lead.—*U. S.* Specific gravity 1.228 *U. S.*, 1.275 *Br.*, 1.235 to 1.240 *P. G.*, 1.32 *F. Cod.*

Preparation.—Acetate of Lead 170 parts (1700 grains or 3 $\frac{1}{4}$ oz. av.); Oxide of Lead 120 parts (1200 grains or 2 $\frac{1}{2}$ oz. av.); Distilled Water a sufficient quantity; to make 1000 parts (10,000 grains or 23 oz. av.). Dissolve the acetate of lead in 800 parts (8000 grains or 18 $\frac{1}{2}$ oz. av. or 17 $\frac{1}{2}$ fluidounces) of boiling distilled water in a glass or porcelain vessel. Then add the oxide of lead, and boil for half an hour, occasionally adding enough hot distilled water to make up the loss by evaporation. Remove the heat, allow the liquid to cool, and add enough distilled water, previously boiled and cooled, to make the product weigh 1000 parts (10,000 grains or 23 oz. av.). Finally, filter the liquid in a well-covered funnel. Solution of subacetate of lead should be kept in well-stoppered bottles.—*U. S.*

Acetate of lead 5 oz. av.; oxide of lead 3 $\frac{1}{2}$ oz. av.; distilled water 20 oz. av. Boil as above, and make the filtrate measure 20 Imperial fluidounces (19 $\frac{1}{4}$ fluidounces *U. S.*)—*Br.*

Acetate of lead 3 parts; oxide of lead 1 part; distilled water 8 parts. Boil and preserve the weight.—*F. Cod.*

Acetate of lead 3 parts; oxide of lead 1 part; water $\frac{1}{2}$ part. Melt at the heat of a water-bath until the mixture has become white or nearly so; then add 9 $\frac{1}{2}$ parts of water, set aside to settle, and filter.—*P. G.*

Several basic acetates of lead, soluble or insoluble in water, are known, which may be obtained by treating solutions of the neutral acetate with the requisite quantity of oxide of lead. The exact composition of the pharmacopœial solutions depends, therefore, upon the proportion of the two compounds named. Döbereiner, Berzelius, and others suggested to use them in the proportion of their molecular weights, so as to form $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{Pb}(\text{HO})_2$. This proportion is closely adhered to by the U. S. and Br. Pharmacopœias, both authorities using nearly 6 molecules of the oxide to 5 of the acetate, so that the solutions must contain chiefly the acetate named, and in addition thereto a small quantity of the triplumbic acetate, $2\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{Pb}(\text{HO})_2$. On the other hand, the French and German preparations are made with very nearly 3 molecules of acetate to 2 of oxide of lead, and contain, therefore, about equal molecules of the two basic acetates. Both these salts are crystallizable from alcohol, in which solvent they are less freely soluble than in water. A still more basic triplumbic acetate, $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{Pb}(\text{HO})_2$, may also be obtained in white needles, but is insoluble in strong alcohol. In preparing these compounds a nearly insoluble sexplumbic acetate, $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 5\text{Pb}(\text{HO})_2$, is formed in variable proportions, and is filtered off. This insoluble compound is included in the total weight directed by three of the above formulas, while that of the British Pharmacopœia orders the filtrate to be brought to a definite measure. The filtered product, *U. S. P.*, weighs about 950 parts (about 21½ oz. av. = 17 fluidounces).

The combination of the chemicals may be effected at the ordinary temperature by macerating the finely-leigated litharge with the solution of lead acetate in a corked bottle, and agitating occasionally until the sediment has become white; from 2 to 4 days are usually required. By boiling all the ingredients the same result is obtained in a much shorter time, and the process is preferable to that of the German Pharmacopœia.

Properties.—Solution of subacetate of lead is a colorless liquid having a sweet, astringent taste and an alkaline reaction to test-paper; the specific gravity has been given above. On exposure to air, or on being mixed with water containing air in solution, the solution yields a white precipitate of carbonate of lead. It unites readily with liquid and solid fats, and may be mixed with an equal bulk of alcohol without precipitating. Added to a solution of gum-arabic, a dense white precipitate is produced; otherwise it has the reactions of lead acetate.

Tests.—After acidulating the solution with acetic acid, ferrocyanide of potassium should produce a white precipitate free from any blue (iron) or red (copper) tint. When completely precipitated by an excess of sulphuric acid the filtrate, on being evaporated to dryness, should leave no residue or only a very slight one (absence of other salts). When precipitated by an excess of ammonia the filtrate should not have a blue color (absence of copper). “13.7 Gm. of the solution should require for complete precipitation 25 Cem. of the volumetric solution of oxalic acid.”—*U. S.* (284.5 grains of the solution and 500 grain-measures of the volumetric solution, *Br.*).

Off. Prep.—*Cerat. plumbi subacet.* (*Ung. plumbi subacet. comp.*), *U. S.*, *Br.*; *Lini-mentum plumbi subacet.*, *U. S.*; *Liquor plumbi subacet. dilutus*, *U. S.*, *Br.*

Medical Action and Uses.—This solution has occasioned violent toxic symptoms when taken internally, which it never should be for medicinal purposes. It is employed whenever an astringent and local sedative action is required to allay pain or inflammation, to constrict flaccid tissues, or to lessen secretion. When applied to the denuded cutis its use should not be continued long, lest acute poisonous effects be developed. It is of common use, diluted, in the treatment of *contusions, sprains, excoriations, fractures, burns, wounds, abscesses, hernia, hemorrhoids*, and various cutaneous eruptions of an inflammatory sort. It is best applied on soft cloths, lint, etc., which should be covered with a waterproof tissue. Spongio-piline is a convenient vehicle for its use. The mucilage of slippery elm or of quince-seeds causes a precipitation of the lead from this solution; flaxseed and sassafras-pith mucilages are less objectionable. For practical use the diluted solution is in most cases preferable.

LIQUOR PLUMBI SUBACETATIS DILUTUS, *U. S.*, *Br.*—DILUTED SOLUTION OF SUBACETATE OF LEAD.

Aqua plumbi, *P. G.*; *Aqua plumbica (vel saturnina)*.—*Lead-water*, *E.*; *Eau de saturne*, *Eau blanche*, *Fr.*; *Bleiwasser, Kühlwasser*, *G.*

Preparation.—Solution of Subacetate of Lead 3 parts (90 grains or 77 minims); Distilled Water 97 parts (2910 grains or 6½ oz. av. or 6½ fluidounces); to make 100 parts (3000 grains = 6½ fluidounces). Mix the solution of subacetate of lead with the dis-

tilled water, previously boiled and cooled. Keep the liquid in well-stopped bottles.—*U. S.*

Take of solution of subacetate of lead, rectified spirit, each 2 fluidrachms; distilled water 19½ fluidounces. Mix, and filter through paper. Keep the clear solution in a stoppered bottle.—*Br.*

The use of distilled water does not prevent the mixture from becoming turbid at once, the carbonic acid held in solution or contained in the atmosphere producing some carbonate of lead; this gas is therefore expelled by the previous boiling of water. Since, however, the decomposition will again take place when exposed to the atmosphere, it is best to prepare lead-water only in small quantities; for preparing 2 fluidounces of it 28½ grains or 244 minims of Goulard's extract are required; the French and German Pharmacopœias order 2 per cent.

AQUA PLUMBI GOULARDI. AQUA VEGETO-MINERALIS GOULARDI VEL LOTIO PLUMBEA.—Goulard's lead-water, *E.*; Eau de Goulard, *Fr.*; Goulardsches Wasser, *G.*—This contains a little alcohol (*Br.*) or vulnerary spirit (*F. Cod.*), the latter being an aromatic alcohol.

Medical Uses.—It is this rather than the stronger solution of subacetate of lead that is commonly employed for the various purposes above indicated. When it is used as a lotion merely, and is not confined by dressings, it is rendered more efficient by the addition of alcohol, in the proportion of 3 or 4 drachms to a pint (℥m. 12–16 in ℥m. 500) of the solution.

LIQUOR POTASSÆ, *U. S.*, *Br.*—SOLUTION OF POTASSA.

Liquor kali caustici, *P. G.*; *Kali hydricum solutum*, *Licivium causticum*.—*Solution of potash*, *E.*; *Potasse caustique liquide*, *Lessive caustique*, *Fr.*; *Aetzkalilauge*, *Kalilauge*, *G.*

An aqueous solution of hydrate of potassium, KHO; molecular weight 56.7—containing about 5 per cent. *U. S.*, 5.84 per cent. *Br.*, 15 per cent. *P. G.*, of the hydrate. Specific gravity 1.036 *U. S.*, 1.058 *Br.*, 1.142 to 1.146 *P. G.*

Preparation.—Bicarbonate of Potassium 90 parts (4½ oz. av.); Lime 40 parts (2 oz. av.); Distilled Water a sufficient quantity. Dissolve the bicarbonate of potassium in 400 parts (20 oz. av. or 19¼ fluidounces) of distilled water; heat the solution until effervescence ceases, and then raise it to boiling. Slake the lime and make it into a smooth mixture with 400 parts (20 oz. av. or 19¼ fluidounces) of distilled water, and heat it to boiling. Then gradually add the first liquid to the second, and continue the boiling for 10 minutes. Remove the heat, cover the vessel tightly, and when the contents are cold add enough distilled water to make the whole mixture weigh 1000 parts (50 oz. av. = 47½ fluidounces). Lastly, strain it through linen, set the liquid aside in a well-stopped bottle until it is clear, and remove the clear solution by means of a siphon.

Solution of potassa may also be prepared in the following manner: potassa 56 parts (27 grains); distilled water 944 parts (455½ grains or 1 fluidounce); to make 1000 parts (a little over 1 fluidounce). Dissolve the potassa in the distilled water.

The potassa used in this process should be of the full strength directed by the Pharmacopœia (90 per cent.). Potassa of any other strength, however, may be used if a proportionately larger or smaller quantity be taken, the proper amount for the above formula being ascertained by dividing 5000 by the percentage of absolute potassa (hydrate of potassium) contained therein. Solution of potassa should be kept in well-stopped bottles.—*U. S.*

Take of carbonate of potash 1 pound; slaked lime 12 ounces; distilled water 1 gallon (Imperial). Dissolve the carbonate of potash in the water, and, having heated the solution to the boiling-point in a clean iron vessel, gradually add the washed slaked lime, and continue the ebullition for 10 minutes with constant stirring. Then remove the vessel from the fire, and when, by the subsidence of the insoluble matter, the supernatant liquor has become perfectly clear, transfer it by means of a siphon to a green glass bottle furnished with an air-tight stopper, and add distilled water if necessary to make it correspond with the tests of specific gravity and neutralizing power.—*Br.*

On bringing together potassium carbonate and slaked lime in the presence of water a double decomposition is effected, resulting in the formation of potassium hydrate and calcium carbonate; $K_2CO_3 + CaH_2O_2$ yields $2KHO + CaCO_3$. This reaction cannot be completed in concentrated solutions, but occurs promptly in diluted liquids. The smallest quantity necessary for 1 part of potassium carbonate, according to Watson, is 8 parts of water; Mohr, however, prefers to use not less than 12 parts, and to concentrate the

caustic liquor, if necessary, by evaporation. The decomposition may be effected in the cold by frequent agitation, but the resulting calcium carbonate is then light and retains much of the liquor, while at the same time silica, if present in the carbonate, is not completely removed. The British Pharmacopœia uses potassium carbonate and water in the proportion of 1 to 10; the United States Pharmacopœia, nearly in the proportion of 1 to 12½, having substituted the much purer bicarbonate for the carbonate. 1 part of slaked lime is sufficient to decompose 2.5 parts of potassium carbonate, containing 81 per cent. of the pure anhydrous salt, and for 1.8 parts of potassium bicarbonate if in boiling the solution of the latter carbonic acid was not given off, or for 3.6 parts of the latter salt if previously converted into normal carbonate by boiling. An excess of lime is, however, preferable to ensure complete decomposition; but the employment of an unnecessarily large quantity may be avoided by following the directions of the Pharmacopœia to add the milk of lime gradually in small portions to the boiling alkaline liquid; when this addition amounts to a quantity of lime equal to about one-half the weight of the potassium salt, a little of the boiling mixture may be poured upon a small moistened filter, and the filtrate collected in a test-tube containing some hydrochloric acid. Should effervescence occur, the boiling must be continued and more lime added, until on testing as before, a new filter being used each time, no effervescence is observed. The removal of the caustic liquor may be effected either by filtering it at once through muslin, or, better still, we think, by allowing the insoluble matter to subside, drawing off the clear liquor by means of a siphon, and transferring the sediment before it has become hard upon a muslin strainer, and washing the potassa out by means of distilled water. In all cases the liquid should be brought to the proper density by the addition of water, or, if necessary, by evaporation; if largely diluted by washing, the potassa solution may be employed for various chemical operations. A well-cleaned iron vessel is best adapted for the above operation.

Other methods for obtaining potassa solution adapted for special purposes have been recommended. Schubert decomposed potassium sulphate accurately by a hot solution of baryta. Hunter (1866) arrived at the same result by substituting lime for the baryta, and by boiling and filtering under a pressure of about 40 pounds to the square inch. F. Schulze (1861) heated a mixture of 1 part of pure potassium nitrate with 3 parts of ferrous oxalate to dull redness while hydrogen gas was being conducted to the bottom of the crucible. Wöhler's process (1853), to heat a mixture of 1 part of potassium nitrate and 2 of copper to dull redness, is apt to yield a product containing potassium nitrite if the mixture has not been intimate or if the heat is not continued long enough; Polacci (1872) found the solution in water to contain a little copper.

The following table, computed by Gerlach (1869), gives the specific gravity of potassa solution at 15° C. (59° F.), containing from 1 to 60 per cent. of potassium oxide, and the same percentage of potassium hydrate:

Per-centage.	K ₂ O.	KHO.	Per-centage.	K ₂ O.	KHO.	Per-centage.	K ₂ O.	KHO.
1	1.010	1.009	21	1.230	1.188	41	1.522	1.425
2	1.020	1.017	22	1.242	1.198	42	1.539	1.438
3	1.030	1.025	23	1.256	1.209	43	1.554	1.450
4	1.039	1.033	24	1.270	1.220	44	1.570	1.462
5	1.048	1.041	25	1.285	1.230	45	1.584	1.474
6	1.058	1.049	26	1.300	1.241	46	1.600	1.488
7	1.068	1.058	27	1.312	1.252	47	1.615	1.499

Properties.—Potassa solution is a clear and colorless liquid of the specific gravity stated above, and has a strong alkaline reaction and a very caustic taste. The slight

peculiar odor which it usually has is due to its action upon organic bodies which may have been derived from the atmosphere. It dissolves wool, skin, and other animal and many vegetable substances, and decomposes fats, forming therewith soluble soaps. It attracts carbonic acid from the air with great avidity, and must therefore be preserved in well-stopped bottles. (Green glass, free from lead, is best adapted for the purpose, but is likewise somewhat decomposed by alkalis, which cause the stopper to become firmly fastened into the bottle unless protected by a thin layer of paraffin. Potassa solution decomposes the salts of ammonium, of the metals, and of all the alkaloids, and induces the decomposition of tannin and its derivatives; "a drop taken up by a platinum loop and held in a non-luminous flame imparts to it a violet tint."—*U. S.* As a test of identity, and considering the strong yellow color given by sodium compounds, the flame may be examined through a blue glass to cut off the color of sodium. It differs from soda solution in yielding a white crystalline precipitate with excess of concentrated solution of tartaric acid, and a yellow one on the addition of hydrochloric acid and platinic chloride.

Tests.—The solution should not effervesce, or at most should give off only isolated bubbles, when dropped into an excess of dilute hydrochloric acid (limit of carbonate). Carbonic acid is limited to about $\frac{1}{3}$ per cent. by the following test: Mix 1 part of potassa solution with 4 parts of lime-water; boil, and filter into nitric acid, when no effervescence should be observed.—*P. G.* When acidulated with nitric acid, potassa solution should give not more than a very slight turbidity with barium nitrate (sulphate), silver nitrate (chloride), or sodium carbonate (alumina, lime); and when the acidulated solution is evaporated to dryness the residue should form a clear or merely a slightly turbid (from presence of silica) solution in water, which should not be disturbed by test solution of magnesium (absence of phosphate). If neutralized with sulphuric acid, and then mixed with half its bulk of concentrated sulphuric acid and allowed to cool, the addition of ferrous sulphate should not produce a black or blackish-brown color (nitrate). Potassa solution should not be precipitated or colored black by hydrogen sulphide, either before or after being acidulated (absence of metals). The British Pharmacopœia demands that 462.9 grains (1 fluidounce Imperial) should require for neutralization 482 grain-measures of the volumetric solution of oxalic acid, which corresponds to 5.84 per cent. by weight of potassium hydrate, or 27 grains in 1 (Imperial) fluidounce. The solution of the United States Pharmacopœia should require for 28 Gm. not less than 25 Cem. of the volumetric solution of oxalic acid, and the (*U. S.*) fluidounce should contain 23.5 grains of pure potassium hydrate.

Pharmaceutical Uses.—By evaporating the solution it yields Potassa (Potassa caustica). *U. S., Br.* It is employed in the official processes for the following: Hydragr. oxid. flavum, *U. S.*; Potassii bromidum, Potassii iodidum, *Br.*

Physiological Action.—Solution of potassa possesses in a degree the caustic properties of the pure alkali, since it contains nearly 6 per cent. of the latter. The soapy feel which it gives to the fingers is due to its combination with the unctuous secretion of the skin. In medicinal doses and taken during or after a meal it speedily combines with the acids then abundantly secreted by the stomach, but if properly diluted and used when the stomach is empty it is absorbed, and tends to neutralize the acid secretions, especially the urine, along with which it is chiefly eliminated. Used habitually, it lessens the coagulability of the blood and dissolves out the hæmatin from the red corpuscles, giving rise to paleness and puffiness of the skin, passive hæmorrhages, general emaciation, and, in a word, to the ordinary phenomena of scurvy. This aplastic operation explains its efficacy in moderating a tendency to plastic exudations, in promoting the absorption of those already existing, and in modifying nutrition generally.

Medical Uses.—Solution of potassa limits or suspends the formation of *acid urinary deposits* and *concretions* by neutralizing the free acids through which they are formed, while it spares the urinary passages the irritation of their contact. But since these acids always proceed from some defect of primary assimilation, the mere neutralization of them when formed does not necessarily effect a radical cure, which must be sought by the use of remedies tending to bring the digestive powers and the work of digestion into due proportion and harmony. For this purpose dietetic and hygienic measures are the most efficient. The *dyspeptic symptoms* which call for solution of potassa and other antacid medicines are heartburn, sour eructations, aphthæ, œsophageal spasm, vomiting, cramp in the stomach, colic, and irregular diarrhœa. It is probable that such medicines, by correcting acidity, tend to promote the due digestion of food, and thereby indirectly to remove the debility of the system upon which *acid dyspepsia* depends.

Certain it is, that in cases of "uric-acid diathesis," as it has been called, the alkaline treatment, duly carried out, will sometimes suspend the faulty secretion for an indefinite period. It is true that this result is more usual after the liberal use of diuretic mineral waters, which probably cleanse the urinary channels of accumulated deposits, than from the use of solution of potassa or of any other alkali alone. The *tympanites* incident to this form of dyspepsia is best palliated by the medicine when it is given in a bitter infusion. *Strangury* from cantharides is said to be both prevented and relieved by 20 minims of solution of potassa, largely diluted. In *acne* of the face (*gutta rosacea*) the internal use of the medicine is sometimes very efficient, and it has been equally recommended for the prevention and cure of *boils* when they occur in successive crops. *Scrofulous glandular swellings* are doubtless diminished during a course of this medicine, but its debilitating effects upon the system should at the same time be counteracted by appropriate food and cod-liver oil. It is injurious in *phthisis*, but, on the other hand, useful in *chronic bronchitis*, especially when associated with emphysema and when expectoration is difficult and the sputa are scanty and tenacious. The mode of action implied in some of the preceding statements receives a further support by the successful use of solution of potassa to moderate *obesity*. The hypothesis invoked to explain its action is that "it increases the vital powers of metamorphosis, by saponifying in part the fat contained in the blood and enabling it to be burnt off as carbonic acid." We should incline to the opinion that it acts by slowly poisoning the victim, radically disorganizing his blood, and hindering his nutrition. For the purpose intended it has been given in the dose of 1 or 2 fluidrachms three times a day—a dose which probably no stomach could long receive with impunity. Experiments and observations in India furnish some reason for thinking that solution of potassa is an antidote to *serpents' bites*. They are not, however, conclusive. Nor is the statement more probable that if used to cauterize the bites of rabid animals it will prevent *hydrophobia*. The power of this solution to dissolve organic products has been used to soften the nail in cases of *ingrown nail*, and gradually to permit its removal, leaving the fungous granulations free from its irritation. It has been recommended to add solution of potassa to the lime-water used for atomized inhalation in *diphtheritic* affections of the throat and larynx, in the proportion of 10 or 15 drops to 5 or 6 ounces of lime-water diluted one-half with pure water. When swallowed in poisonous doses the proper antidote against its effects is vinegar or lemon-juice, followed by some bland oil.

Solution of potassa may be administered internally in the *dose* of from 10 minims to a fluidrachm (Gm. 0.60–4), largely diluted with a mucilaginous or sweetened aromatic or a bitter infusion. It should not be prescribed along with henbane, belladonna, or stramonium, whose medicinal properties it destroys.

LIQUOR POTASSÆ EFFERVESCENS, *Br.*—EFFERVESCING SOLUTION OF POTASH.

Aqua potassæ effervescens.—Potash-water, E.; *Eau alcaline gazeuse*, Fr.; *Alkalisches Mineralwasser*, G.

Preparation.—Take of Bicarbonate of Potash 30 grains; Water 1 pint (Imperial). Dissolve the bicarbonate of potash in the water and filter the solution; then pass into it as much pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk, as can be introduced with a pressure of seven atmospheres. Keep the solution in bottles securely closed to prevent the escape of the compressed gas.—*Br.*

Properties and Tests.—The solution effervesces strongly when the containing vessel is opened, carbonic acid gas escaping; it is clear and sparkling, and has an agreeable acidulous taste. 10 fluidounces, after being boiled for 5 minutes, require for neutralization 150 grain-measures of the volumetric solution of oxalic acid. 5 fluidounces, evaporated to one-fifth, and 12 grains of tartaric acid added, yield a crystalline precipitate which, when dried, weighs not less than 12 grains.

Medical Uses.—The remarks made under LIQUOR MAGNESIÆ CARBONATIS are applicable to this preparation.

LIQUOR POTASSII ARSENITIS, *U. S.*—SOLUTION OF ARSENITE OF POTASSIUM.

Liquor arsenicalis, Br.; *Liquor kali arsenicosi*, P. G.; *Solutio arsenicalis Fowleri*, *Kali arsenicosum solutum.*—Arsenical solution, *Fowler's solution*, E.; *Liqueur (solution) arsenicale de Fowler*, Fr.; *Fowler'sche Tropfen*, G.

The official solutions contain 1 part of arsenious acid in 100 parts by weight, *U. S.*, *Br.*, *F. Cod.*, *P. G.*

Preparation.—Arsenious Acid, in small pieces, 1 part (30 grains); Bicarbonate of Potassium 1 part (30 grains); Compound Tincture of Lavender 3 parts (90 grains = 100 minims); Distilled Water a sufficient quantity; to make 100 parts (3000 grains). Boil the arsenious acid and bicarbonate of potassium in a glass vessel with 10 parts (300 grains or 5 fluidrachms) of distilled water until the acid is completely dissolved. Then add the compound tincture of lavender, and enough distilled water to make the product weigh 100 parts (3000 grains or $6\frac{1}{2}$ oz. av. = $6\frac{1}{2}$ fluidounces). Lastly, set the mixture aside for 8 days, and then filter through paper.—*U. S.*

Take of arsenious acid, in powder, carbonate of potassium, each 87 grains; compound tincture of lavender 5 fluidrachms; distilled water a sufficiency. Place the arsenious acid and the carbonate of potash in a flask with 10 ounces of the water and apply heat until a clear solution is obtained. Allow this to cool. Then add the compound tincture of lavender and as much distilled water as will make the bulk 1 pint (Imperial).—*Br.*

The United States Pharmacopœia very properly directs the mixture of potassium salt and arsenious acid to be boiled in a small quantity of water, whereby a combination and solution is readily effected, the liquid containing potassium arsenite, which is probably HK_2AsO_3 . When this is subsequently diluted with water and remains in contact with the air, it absorbs carbonic acid again, and the solution will then be identical with that of the British Pharmacopœia, which must be regarded merely as a solution of arsenious acid in the alkaline carbonate, from which a portion crystallizes again when the solution is long kept. On keeping 100 Gm. for 3 years, Ménére (1876) collected 0.15 Gm., or 15 per cent. of the amount originally dissolved. The precise circumstances under which this separation takes place have not been ascertained, but the separation is undoubtedly due to the gradual conversion of the arsenious acid into the crystalline modification, which is but sparingly soluble. Observations made by Fresenius, Dannenberg, and others indicate that in partially-filled bottles the arsenious acid is gradually oxidized to arsenic acid, which is considered to be far less poisonous than the former. It is evident, therefore, that Fowler's solution cannot be kept unchanged for an indefinite period, and it is advisable that it be prepared in no larger quantities than will be sufficient for a few months or a year, or that it be kept in small well-sealed bottles, whereby oxidation is prevented, as well as the appearance of a fungous growth which often takes place in Fowler's solution on exposure to the air. Delahaye (1882) regards the excess of alkali used as favoring this growth, and recommends reducing the potassium to the quantity absolutely necessary for retaining the arsenic in permanent solution, or, better still, replacing it by sodium bicarbonate, 2 parts of which will be sufficient for 3 parts of arsenious acid; these changes, however, do not prevent the development of mould, though they may possibly retard it.

Properties.—Fowler's solution is a reddish liquid, at first somewhat opalescent, having an alkaline reaction to test-paper and the odor of lavender; that of the French and German Pharmacopœias is colorless, and is flavored with compound spirit of melissa. Its specific gravity is 1.009. It gives the usual reactions of arsenic, and requires to be acidulated with hydrochloric acid before it will be precipitated by hydrogen sulphide.

Tests.—On being acidulated with hydrochloric acid the solution should not acquire a yellow color or deposit a yellow precipitate (absence of sulphide of arsenic).

The amount of arsenious acid contained in it is conveniently ascertained with iodine, with starch-paste as an indicator, which is not permanently colored blue until the arsenious has all been oxidized to arsenic acid, hydriodic acid being formed at the same time: $\text{As}_2\text{O}_3 + 5\text{H}_2\text{O} + 2\text{I}_2$ yields $2\text{H}_3\text{AsO}_4 + 4\text{HI}$. "If 24.7 Gm. of the solution are boiled with 0.5 Gm. of bicarbonate of sodium, the liquid, when cold, diluted with 100 Ccm. of water, and some gelatinized starch added, it should require from 48.5 to 50 Ccm. of the volumetric solution of iodine until the blue color ceases to disappear on stirring (corresponding to 1 per cent. of arsenious acid of the required purity)."—*U. S.* Or, "5 Gm. of solution, mixed with 20 Gm. of water, 1 Gm. of sodium bicarbonate, and a few drops of starch solution, should decolorize 10 Ccm. of the volumetric solution of iodine, and on the further addition of 0.1 Ccm. of the latter should acquire a blue color."—*P. G.* "442 grains (1 fluidounce), 10 grains of sodium bicarbonate, and 6 fluidounces of distilled water containing a little mucilage of starch, treated as described, require 875 grain-measures of the volumetric solution of iodine, indicating $4\frac{1}{2}$ grains of arsenious acid."—*Br.*

Medical Uses.—The action and uses of this medicine have been sufficiently discussed elsewhere. (See *ACIDUM ARSENIOSUM*.) It is sufficient in this place to state

that its efficacy is most conspicuous in *squamous diseases of the skin, intermittent fever, neuralgia*, especially of the trifacial, and in *nervous asthma*. The commencing dose should not exceed 5 drops (Gm. 0.30), nor should it be given when the stomach is empty, nor unless greatly diluted.

LIQUOR POTASSII CITRATIS, U. S.—SOLUTION OF CITRATE OF POTASSIUM.

Liquor kali citrici.—*Citrate de potasse liquide*, Fr.; *Kaliumcitrat-Lösung*, G.

Preparation.—Citric Acid 6 parts (60 grains); Bicarbonate of Potassium 8 parts (80 grains); Water a sufficient quantity. Dissolve the citric acid and the bicarbonate of potassium each in 40 parts (400 grains or 7 fluidrachms) of water. Filter the solutions separately, and wash the filters with enough water to obtain in each case 50 parts (500 grains) of solution. Finally, mix the two solutions, and when effervescence has ceased transfer the liquid to a bottle. This preparation should be freshly made when wanted for use.—U. S.

This is a solution of potassium citrate containing a little free carbonic acid, and differs from *Mistura potassii citratis* in the absence of the yellowish color and the agreeable lemon flavor. The improved manipulation suggested in the previous editions of this work, now adopted by the Pharmacopœia, consists in dissolving the chemicals separately and mixing the clear solutions; a sufficient amount of carbonic acid gas will thus be retained to render the liquid sparkling and impart to it a pleasant acidulous flavor aside from the mildly saline taste of potassium citrate. The quantities given above will almost exactly make 2 fluidounces of the solution, and this contains an excess of 3.4 grains of citric acid over the amount necessary for the production of normal potassium citrate, of which the solution contains nearly 9 per cent. The Pharmacopœia gives the specific gravity 1.059, which is obviously an approximation, the density varying with the carbonic acid retained. The direction to make the solution fresh as wanted is a commendable one, since aqueous solutions of citric acid undergo decomposition (see page 53).

POTIO RIVERI, *P. G.*, is less than one-third the strength of the preceding; it is made from citric acid 4 parts, water 190 parts, and crystallized sodium carbonate 9 parts.

POTIO DE RIVIERE, *P. Cod.* Dissolve citric acid and potassium bicarbonate, of each 2 Gm., separately in water 50 Gm. and syrup 15 Gm.; the solutions are often dispensed in separate vials.

Medical Action and Uses.—This preparation is nearly identical in its action with *Mistura potassii citratis*, *U. S. P.*, and *Liq. potassii effervescens*, *Br. P.*, and with the effervescing draught prepared extemporaneously. When the intention is solely to affect the system after the absorption of the salt, either of the first two will lessen the tension of the capillaries and promote *diaphoresis*; but when it is intended at the same time to make an impression upon the stomach itself, the carbonic acid extricated during effervescence becomes an important part of the dose. The primary action of the gas is to stimulate organically, while it perhaps anæsthetizes, the gastric mucous membrane, as may be inferred from the many cases of gastric hyperæmia and irritation in which it allays *nausea* and *vomiting*. It may therefore be sometimes used with advantage when the stomach is disordered, although fever may be absent. Either solution may have its diaphoretic power increased by the addition of spirit of nitrous ether, of solution of morphine, or of antimonial wine or tartar emetic, in very small, non-nauseating doses.

The *dose* of the neutral mixture is a tablespoonful (Gm. 16); of the effervescing mixture, a tablespoonful (Gm. 16) of each of the two solutions should be mixed, and swallowed while effervescing. The dose should be repeated every hour until the object in view is attained or defeated.

LIQUOR POTASSII PERMANGANATIS, Br.—SOLUTION OF PERMANGANATE OF POTASSIUM.

Liquor potassæ permanganatis.—*Soluté de permanganate de potasse*, Fr.; *Kaliumpermanganat-Lösung*, G.

Preparation.—Take of Permanganate of Potassium 88 grains; Distilled Water 1 pint (Imperial). Dissolve.—*Br.*

The solution contains 1 per cent. of permanganate of potassium, and has the purple color and the chemical behavior of the salt.

Medical Uses.—The official solution, of 4 grains of the salt to an ounce of distilled water, appears unnecessary, since it is too weak for many purposes and too strong for others. (For its uses and doses see POTASSII PERMANGANAS.)

LIQUOR SODÆ, U. S., Br.—SOLUTION OF SODA.

Liquor natri caustici, P. G.; *Natrum hydricum solutum*.—*Soude caustique liquide*, *Lessive des savonniers*, Fr.; *Aetznatronlauge*, G.

An aqueous solution of hydrate of sodium, NaHO ; molecular weight 40—containing 5 per cent. U. S., 4.1 per cent. Br., 15 per cent. P. G., 23 per cent. F. *Cod.*, of the hydrate. Specific gravity of the official solutions: 1.059 U. S., 1.047 Br., 1.33 F. *Cod.*, 1.159 to 1.163 P. G.

Preparation.—Carbonate of Sodium 180 parts (9 oz. av.); Lime 60 parts (3 oz. av.); Distilled Water a sufficient quantity. Dissolve the carbonate of sodium in 400 parts (20 oz. av. or $19\frac{1}{4}$ fluidounces) of boiling distilled water. Slake the lime, and make it into a smooth mixture with 400 parts (20 oz. av. or $19\frac{1}{4}$ fluidounces) of distilled water, and heat it to boiling. Then gradually add the first liquid to the second, and continue the boiling for 10 minutes. Remove the heat, cover the vessel tightly, and when the contents are cold add enough distilled water to make the whole mixture weigh 1000 parts (50 oz. av. = 42 fluidounces). Lastly, strain it through linen, set the liquid aside in a well-stopped bottle until it is clear, and remove the clear solution by means of a siphon.

Solution of Soda may also be prepared in the following manner: Soda 56 parts; distilled water 944 parts; to make 1000 parts. Dissolve the soda in the distilled water. The soda used in this process should be of the full strength directed by the Pharmacopœia (90 per cent.). Soda of any other strength, however, may be used if a proportionately larger or smaller quantity be taken, the proper amount for the above formula being ascertained by dividing 5000 by the percentage of absolute soda (hydrate of sodium) contained therein. Solution of soda should be kept in well-stopped bottles.—U. S.

Take of carbonate of soda 28 ounces; slaked lime 12 ounces; distilled water 1 gallon. Dissolve the carbonate of soda in the water, and, having heated the solution to the boiling-point in a clean iron vessel, gradually add the washed slaked lime, and continue the ebullition for 10 minutes, with constant stirring. Then remove the vessel from the fire, and when, by the subsidence of the insoluble matter, the supernatant liquor has become perfectly clear, transfer it by means of a siphon to a green glass bottle furnished with an air-tight stopper, and add distilled water, if necessary, to make it correspond with the tests of specific gravity and neutralizing power.—Br.

The process is quite analogous to that for the preparation of caustic potassa, and what has been said about the manipulation (see LIQUOR POTASSÆ) applies equally well in this case. 1 part of burned lime, if pure, is sufficient to decompose 5 parts of crystallized sodium carbonate; in both the above formulas the quantity of the former ordered may without disadvantage be reduced.

Properties.—Soda solution is a clear and colorless liquid of the density given above, and has a strong alkaline reaction and a very caustic taste; the peculiar slight odor which it usually has is solely due to the accidental presence of organic matters, which are likely to impart also a yellowish color. It dissolves various organic matters and tissues, and decomposes fats, forming soaps. It has a great affinity for carbonic acid, and should be preserved in well-stopped bottles made of glass free from lead, the stopper being protected by a thin layer of paraffin. In its chemical behavior it closely resembles potassa solution, but, unlike the latter, it does not yield a crystalline precipitate with excess of tartaric acid, except in concentrated solutions; with hydrochloric acid and platinum chloride it does not yield a yellow precipitate, and when, by means of a platinum wire, a drop of it is held in a non-luminous flame, an intense yellow color is imparted to the latter.

Tests.—Soda solution should not effervesce, or at most should evolve only isolated bubbles of carbonic acid gas, on being dropped into an acid. "If 1 part of it be boiled with 4 parts of lime-water, the liquid filtered into nitric acid should not cause any effervescence (not over $\frac{1}{4}$ per cent. carbonic acid as carbonate)."—P. G. The solution acidulated with nitric acid should not cause more than a slight cloudiness with barium nitrate (sulphate), silver nitrate (chloride), or sodium carbonate (alumina, earths), and when evaporated to dryness and redissolved in water should leave only a minute quantity of insoluble matter (silica), and furnish a liquid which is not precipitated by test solution of magnesium (phosphate). The absence of nitrate and of heavy metals is shown as

described for LIQUOR POTASSÆ. "To neutralize 20 Gm. of solution of soda should require not less than 25 Cem. of the volumetric solution of oxalic acid."—*U. S.* 458 grains (1 fluidounce) of the solution require 470 grain-measures of the volumetric solution.—*Br.*

The following table by Gerlach (1869) gives the specific gravity at 15° C. (59° F.) of soda solution containing from 1 to 60 per cent. of sodium oxide and the same percentage of sodium hydrate:

Per-centage.	Na ₂ O.	NaHO.	Per-centage.	Na ₂ O.	NaHO.	Per-centage.	Na ₂ O.	NaHO.
1	1.015	1.012	21	1.300	1.236	41	1.570	1.447
2	1.029	1.023	22	1.315	1.247	42	1.583	1.456
3	1.043	1.035	23	1.329	1.258	43	1.597	1.468
4	1.058	1.046	24	1.341	1.269	44	1.610	1.478

19	1.270	1.213	39	1.543	1.420	59	1.815	1.633
20	1.285	1.225	40	1.558	1.437	60	1.830	1.643

Pharmaceutical Uses.—In preparing Antimon. sulphurat., *U. S.*, *Br.*; Bismuthi oxid., Ferri oxid. magnet., Ferri peroxid. humid., Hydrarg. oxidi flav., Quiniæ sulph., *Br.*; Soda (Soda caust.), *U. S.*, *Br.*; Sodæ valerianas, *Br.*

Allied Preparation.—SODIUM ETHYLATE, C_2H_5NaO , or *caustic alcohol*, was recommended by Dr. B. W. Richardson (1870). Half a fluidounce of absolute alcohol is put into a two-ounce test-tube, immersed in water of 10° C. (50° F.), and metallic sodium is added in small pieces until the evolution of hydrogen ceases, when the temperature is raised to 37.8° C. (100° F.), and the addition of sodium continued until hydrogen ceases to be given off: the compound is then dissolved in half a fluidounce of absolute alcohol. According to Liebig (1837), the action is rapidly completed at 50° C. (122° F.), and on cooling the sodium ethylate crystallizes in large colorless laminae. It may be rubbed into powder and preserved in well-stopped vials.

LIQUOR SODII ETHYLATIS, *Br.*, is made by dissolving metallic sodium 22 grains in ethylic (absolute) alcohol 1 fluidounce, contained in a flask and kept cool by water. It is a colorless, syrupy liquid, of spec. grav. 0.867, becomes brown by keeping, and contains 19 per cent. of NaC_2H_5O .

Medical Uses.—Solution of soda is seldom used therapeutically, and then chiefly in cases of "torpor of the liver." *Dose*, 10 to 60 drops (Gm. 0.60–4), largely diluted.

According to Dr. Richardson, the following are the results of applying *sodium ethylate* to the living tissues: 1, a removal of water from the tissue; 2, the destructive action of the resulting caustic soda; 3, coagulation from the alcohol that is reproduced; 4, prevention of decomposition in the resulting dead tissue. It was employed by Dr. Brunton in the treatment of *navus* in 1871. He describes its action as follows: "Laid on dry parts of the body, the sodium ethylate is comparatively inert, creating no more change than the redness and tingling caused by common alcohol; but as soon as the part to which the substance is applied gives up a little water, the transformation described above occurs, caustic soda is produced in contact with the skin in proportion as water is eliminated, and there proceeds a gradual destruction of tissues which may be moderated so as hardly to be perceptible or may be so intensified as to act almost like a cutting instrument." "Applied direct to the unbroken skin, the destructive action is less painful than would be expected, and when pain is felt it may be checked quickly by dropping upon the part a little chloroform, which decomposes the alcohol, converting it into a chloride salt and ether." "The caustic alcohols may be used in combination with local anæsthesia from cold. A part rendered quite dead to pain by freezing with ether spray may be directly destroyed by the subcutaneous injection of caustic alcohol—a practice very important in the treatment of *poisoned wounds*. It is by no means improbable that *cystic tumors* may be cured by this simple subcutaneous injection of a little of those fluids after

destruction of their sensibility by cold. Potassium and sodium alcohol, added to the volatile hydride of amyl, dissolve the hydride and produce a caustic solution." Dr. Brunton states that, compared with the action of nitric acid, there is but little destruction of the epidermis, and he considers that sodium ethylate acts as an astringent, and the pain is not so severe as that caused by nitric acid. In his cases hardly any scarring ensued. The ethylate affects but little the healthy skin; it restricts its action to the spot on which it is applied. Dr. Richardson (*London Lancet*, Feb. 12, 1881) has reported cases of *tattoo* and *mother's marks*, nasal *polypus*, *ozæna*, and *lupus* in which the caustic produced good results, as well as in minor affections, such as *warts*, small *melanotic growths*, *ringworm*, and *hæmorrhoids*.

Dr. Richardson states that the liberated alcohol coagulates the albuminous compounds in its neighborhood, and thus limits the caustic action of the soda. The red corpuscles become disintegrated, and then crystalline, while the white are for a time left unaffected. The risk of too great hæmorrhage from the rapid action of the ethylate in cases of pendent vascular tumors may be met by diluting the ethylate with alcohol, so as to promote coagulation; and the pain caused by it may be mitigated by mixing it with laudanum. It should be applied with a camel's-hair brush.

LIQUOR SODÆ CHLORATÆ, U. S.—SOLUTION OF CHLORINATED SODA.

Liquor sodæ chlorinatæ, Br.; *Liquor natri chlorati*, *Liquor natri hypochlorosi*.—*Labarraque's solution*, E.; *Chlorure de soude liquide*, *Liquueur de Labarraque*, Fr.; *Chlornatronlösung*, *Bleichflüssigkeit*, G.

A solution of $\text{NaCl} \cdot \text{NaClO}$ in water.

Preparation.—Carbonate of Sodium 100 parts (20 oz. av.); Chlorinated Lime 80 parts (16 oz. av.); Water, a sufficient quantity; to make 1000 parts (200 oz. av.). Mix the chlorinated lime intimately with 400 parts (80 oz. av. = 5 lb. av. or 77 fluidounces) of water in a tared vessel provided with a tightly-fitting cover. Dissolve the carbonate of sodium in 400 parts (80 oz. av. or 77 fluidounces) of boiling water, and immediately pour the latter solution into the former. Cover the vessel tightly, and when the contents are cold add enough water to make them weigh 1000 parts (200 oz. av. = 12½ lb. av. or about 11 pints). Lastly, strain the mixture through muslin, allow the precipitate to subside, and remove the clear solution by means of a siphon. Keep the product in well-stopped bottles.—*U. S.*

Take of chlorinated lime 16 ounces; carbonate of sodium 24 ounces; distilled water 1 gallon. Dissolve the carbonate of sodium in 2 pints of the distilled water; thoroughly triturate the chlorinated lime with 6 pints of the water and filter; mix well the solutions; again filter. Keep the solution in a stoppered bottle in a cool and dark place.—*Br.*

Dry chlorinated lime 100 Gm.; crystallized carbonate of sodium 200 Gm.; distilled water 4500 Gm. Triturate the chlorinated lime in a porcelain mortar with a portion of the water, and separate by decantation the finest portion; triturate the residue, add more of the water, and decant as before; repeat this operation until two-thirds of the water have been used. Dissolve the sodium salt in the remaining water, mix the two liquids, let settle, and filter.—*F. Cod.*

The process of the U. S. Pharmacopœia yields the chlorinated soda by double decomposition of chlorinated lime with sodium carbonate, whereby calcium carbonate is precipitated, the chlorinated soda remaining in solution, together with the sodium chloride resulting from the decomposition of the chloride of calcium present in the lime compound and with the excess of sodium carbonate employed. The solution of sodium carbonate is now directed to be boiling hot when added to the mixture of chlorinated lime and water, the object being the precipitation of a dense calcium carbonate. If no heat is employed, the precipitate will be very light and retain a large proportion of the liquid. But heat should not be applied after the mixture has been made, since the solutions of chlorinated alkalies are decomposed thereby into chloride and chlorate, oxygen being at the same time evolved; in the presence of much free alkali the decomposition takes place less readily. The French Codex directs the same process, the liquids being mixed without heating. For 80 parts of chlorinated lime, 100 parts *U. S.*, 160 parts *F. Cod.*, of crystallized sodium carbonate are used, and sufficient water to make a total weight of 1000 parts *U. S.*, 3840 parts *F. Cod.*; the chlorine strength of the former is therefore nearly four times that of the latter. The liquid which remains mechanically enclosed in

the precipitate may be washed out upon a strainer by water and utilized for bleaching purposes, but owing to its uncertain strength is not adapted for medicinal use.

The Br. P. process differs from the preceding ones mainly in this, that the solution of chlorinated lime is filtered, and that an uncertain quantity of this liquid remains with the insoluble portion. The former directed chlorine gas to be passed into the dissolved sodium carbonate, whereby one-half of the salt is acted upon, resulting in the production of chloride and hypochlorite of sodium and the liberation of carbonic acid, which unites with the other half of the salt to form bicarbonate of sodium; $2\text{Na}_2\text{CO}_3 + \text{Cl}_2 + \text{H}_2\text{O}$ yields $\text{NaCl} \cdot \text{NaClO} + 2\text{NaHCO}_3$. If the action of chlorine is continued, the hypochlorite of sodium is decomposed, chloride of sodium and hypochlorous anhydride being formed; $\text{NaClO} + \text{Cl}_2$ yields $\text{NaCl} + \text{Cl}_2\text{O}$. This last-mentioned compound, which has a yellowish color, seems to decompose the bicarbonate with difficulty.

Properties.—The solution is clear and colorless, not pale-greenish, as described by the U. S. Pharmacopœia, a yellowish color being imparted only when the process of the British Pharmacopœia has been followed and an excess of chlorine has been used. Its specific gravity is 1.044. It has a feeble odor of chlorine, and a saline somewhat styptic and sharp alkaline taste, and bleaches indigo, litmus, and vegetable colors like chlorine, but less energetically. With solution of ferrous sulphate it produces a brown precipitate of ferric hydrate, and with solution of lead salt a brown one of lead dioxide; the color of both precipitates is lighter, from carbonate present, if an excess of the metallic salts be used. On the addition of hydrochloric acid effervescence takes place, the gas consisting of carbonic acid and chlorine, the latter resulting from the mutual reaction of the hydrochloric and hypochlorous acids; thus: $\text{NaCl} \cdot \text{NaClO} + 2\text{HCl} = 2\text{NaCl} + \text{HCl} + \text{HClO}$, and $\text{HCl} + \text{HClO} = \text{Cl}_2 + \text{H}_2\text{O}$. It is upon the amount of this available chlorine that the value of this preparation depends.

Tests.—Solution of chlorinated soda is not precipitated by ammonium oxalate (absence of calcium). "8.88 Gm. of the solution, when mixed with a solution of 2.6 Gm. of iodide of potassium in 200 Ccm. of water, and afterward with 18 Gm. of hydrochloric acid and a little gelatinized starch, should require, for complete decoloration, not less than 50 Ccm. of the volumetric solution of hyposulphite of sodium (corresponding to at least 2 per cent. of available chlorine)."—U. S. The chlorine set free liberates an equivalent quantity of iodine, which imparts a blue color to the solution containing starch, and this color disappears on the addition of the hyposulphite. The same process, but without starch, is used by the British Pharmacopœia, 70 grains of the chlorinated solution being mixed with a solution of 20 grains of potassium iodide in 4 fluidounces of water and acidulated with 2 fluidrachms of hydrochloric acid; the brown color should be discharged by 500 grain-measures of the volumetric solution of hyposulphite of sodium, ($2\frac{1}{2}$ per cent. Cl.).

A preparation analogous to the preceding in composition and identical in bleaching effects is *Liquor potassæ chloratæ*, *Chlorinated potassa solution* (Chlorure de potasse, *Fr.*; Chlorkalilösung, *G.*), which is perhaps better known by its French designation, *Eau de javelle*. It is obtained by substituting equivalent quantities of potassium carbonate for the sodium carbonate ordered in the above processes.

Physiological Action.—In animals it produces violent gastro-intestinal irritation, spasms, and death. In man the same symptoms occur from poisonous doses, together with the phenomena of collapse. In medicinal doses it appears to increase the perspiration and urine, to repress mucous profluvia, and to lessen glandular enlargements. Applied locally, it tends to prevent or suspend gangrenous ulceration.

Medical Uses.—Under the impression that its antiseptic qualities fitted it to counteract morbid processes which were theoretically supposed to depend upon putridity, it has been largely employed in *typhoid* fever and typhoid diseases generally, but without obvious advantage. But as a topical application to *gangrenous sores* and to other *unhealthy ulcers*, such as affect the mouth in *mercurialization*, in *diphtheria*, *scarlatina*, and *scurvy*, the nostrils in *ozæna*, the uterus, the vagina, and the *auditory canal*, it corrects the offensive odor of the secretions and stimulates the parts to separate dead tissue and assume a healthy action. For *simple ulcers* of an indolent aspect, especially such as result from *burns*, or which affect the *nipples* and the *genital organs* of females, this liquid generally acts as a wholesome stimulant.

It may be given internally in *doses* varying from 30 to 60 drops (Gm. 2–4) in water or some mild liquid, and repeated every two or three hours. As a gargle it should be diluted with 8 or 10 parts of water, and used of the same strength for an injection into the vagina, uterus, or bladder, and as a lotion for burns, excoriations, and cutaneous eruptions.

LIQUOR SODÆ EFFERVESCENS, Br.—EFFERVESCING SOLUTION OF SODA.

Aqua sodæ effervescens, Aqua alcalina effervescens.—Soda-water, E.; *Eau alcaline gazeuse*, Fr.; *Sodawasser*, G.

Preparation.—Take of Bicarbonate of Soda 30 grains; Water 1 pint. Dissolve the bicarbonate of soda in the water and filter the solution; then pass into it as much pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk, as can be introduced with a pressure of seven atmospheres. Keep the solution in bottles securely closed to prevent the escape of the compressed gas.—*Br.*

This corresponds to the effervescing solution of potash, and has the same physical properties. 10 fluidounces, after being boiled for 5 minutes, require for neutralization 178 grain-measures of the volumetric solution of oxalic acid.—*Br.*

The corresponding solution of the French Codex is made by dissolving 3.12 Gm. (48 grains) of bicarbonate of sodium, 0.23 Gm. (3½ grains) of bicarbonate of potassium, 0.35 Gm. (5½ grains) of sulphate of magnesium, and 0.08 Gm. (1¼ grains) of chloride of sodium in 650 Gm. (21 troyounces) of water, and impregnating the solution with carbonic acid gas.

Medical Uses.—This preparation appears to be superfluous. The quantity of bicarbonate of sodium required in any particular case can be administered in carbonated water.

LIQUOR SODII ARSENIATIS, U. S., Br.—SOLUTION OF ARSENIATE OF SODIUM.

Liquor sodæ arseniatis.—Solution of arseniate of soda, E.; *Liqueur (Solution) d'arsenate de soude*, Fr.; *Arsensaure Natronlösung*, G.

Preparation.—Arsenate of Sodium, deprived of its water of crystallization by a heat not exceeding 149° C. (300° F.), 1 part (46 grains); Distilled Water 99 parts (4554 grains or 10½ oz. av. = 10 fluidounces); to make 100 parts. Dissolve the arseniate of sodium in the distilled water.—*U. S.*

Take of arseniate of sodium (rendered anhydrous by a heat not exceeding 300° F.) 9 grains; distilled water 2 fluidounces. Dissolve.—*Br.*

The *Liqueur arsenicale de Pearson* of the French Codex is made by dissolving 1 part of crystallized arseniate of sodium in 600 parts of distilled water, and is, therefore, only about one-tenth the strength of the above. 1 part of the exsiccated salt is contained in 100 *U. S., Br.*, and about 1000 *F. Cod.*, parts.

The solutions are colorless, and give the reactions of ARSENIATE OF SODIUM, which see.

Medical Uses.—This preparation does not appear to possess any demonstrable advantages over the solution of arseniate of potassium. It may be employed in similar doses, or from 3 to 6 drops (Gm. 0.15–0.30), largely diluted and after meals.

LIQUOR SODII SILICATIS, U. S.—SOLUTION OF SILICATE OF SODIUM.

Liquor natræ silicici, P. G.; *Natrum silicicum solutum, Vitrium solubile.*—Liquid glass, Soluble glass, E.; *Silicate de soude liquide, Verre soluble, Verre liquide*, Fr.; *Natriumsilikat-Lösung, Wasserglas, Natronwasserglas*, G.

Origin.—The element *silicon* or *silicium* (Si; atomic weight 28) is an important constituent of many minerals and rocks. *Rock-crystal* is pure silica or silicic oxide, SiO₂, and *quartz, sand, amethyst, chalcedony, agate, flint*, and other minerals are chiefly composed of the same oxide. A combination of this oxide with alkali and other bases became known at an early date with the discovery of glass; and about 1640, Van Helmont noticed that the compound of silex and salt of tartar (potassium carbonate) would liquefy in a damp atmosphere. This liquid became known as *Liquor silicium*—Liquor of flints, E.; *Liqueur des cailloux*, Fr.; *Kieselweichigkeit*, G. The usefulness of such a solution for rendering inflammable substances incombustible was proved by J. N. Fuchs (1818). In its preparation soda was soon substituted for potash, and the designation "liquid" or "soluble glass" applied indiscriminately to both compounds, which are used in calico-printing, as an addition to cheap soaps, in fresco-painting, for manufacturing artificial stone, for cements, and for other purposes. In 1880 the United States imported over 1,000,000 pounds, in 1882 only 106,101 pounds, of silicate of sodium.

Preparation.—Sodium silicate is usually made by fusing together a mixture of 1 part of fine sand or powdered flint and 2 parts of exsiccated carbonate of sodium, dis-

solving the product in boiling water, filtering, and evaporating; or 8 parts of exsiccated carbonate of sodium, 15 parts of fine sand, and 1 part of charcoal are used, the latter merely serving as a means for facilitating the decomposition of the carbonate, the gas evolved being partly carbonic oxide. L. Buchner recommended as a cheap material for its preparation 10 parts of powdered quartz, 6 parts of calcined sodium sulphate, and $1\frac{1}{2}$ or 2 parts of charcoal. A mixture of soda and potash with silica is more readily fusible than the former. The proportion of the ingredients, however, is varied according to the use to be made of the compound, and a more glass-like and less-readily soluble mass is obtained by the fusion of 2 parts of silica and 3 parts of calcined soda.

Properties.—Silicate of sodium is a transparent glass-like mass, which may be obtained in crystals, Na_2SiO_3 , with variable amounts of water of crystallization. On exposure the salt becomes superficially opaque, and it is slowly soluble in boiling water; but the alkaline solution may be evaporated to a thick syrupy consistence without separating a deposit on cooling. The solution, as met with in commerce, usually contains about 10 to 12 per cent. of soda (NaHO), and 20 to 24 per cent. of silica (SiO_2), and is a transparent or semi-transparent colorless or yellowish viscid liquid, which is inodorous, and has a saline and sharp alkaline taste and an alkaline reaction to test-paper. Its specific gravity varies between 1.30 and 1.40. On acidulating the solution with hydrochloric acid the mixture remains transparent, but the colorless silicic acid forms gradually a dense jelly. If the solution be previously diluted with 10 to 15 parts of water, the silicic acid liberated by the hydrochloric acid will remain dissolved or suspended until the liquid is boiled or evaporated. Alcohol added to the solution produces a gelatinous precipitate of sodium silicate. A drop of the liquid held in a non-luminous flame by means of a loop of platinum wire burns with the intense yellow color of sodium compounds.

Solution of sodium silicate should be preserved in glass or stone vessels, securely stoppered with cork or caoutchouc to prevent access of air and decomposition by carbonic acid gas. Stoppers of glass or stone may be used, but should be well coated with paraffin to prevent their becoming cemented to the neck of the vessel.

Tests.—The only test of purity mentioned by the Pharmacopœia is that a small quantity of the solution should not produce any caustic effect when applied to the skin (absence of an excessive amount of alkali). When mixed with an equal bulk of alcohol any caustic alkali present will remain in solution, and may be recognized by test-paper or estimated by volumetric solution of oxalic acid. On adding excess of hydrochloric acid to the solution, only a moderate effervescence should take place, showing that it has not been injuriously affected by exposure; and on evaporating the acid mixture to dryness a residue partly soluble in water should be left, which is not colored dark by hydrogen sulphide. Should the solution of sodium silicate be strongly alkaline, it may be boiled with gelatinous silicic acid, which will be dissolved by the free alkali.

Other Silicates.—SILICATE OF POTASSIUM is obtained by fusing a mixture of 10 parts of carbonate of potassium, 15 parts of fine sand, and 1 part of charcoal. It closely resembles sodium silicate in all its properties, but is more easily fusible.

SILICATE OF MAGNESIUM. This is found native, and constitutes several well-known minerals, such as *soapstone* or *steatite*, which consists of silicate of magnesium and aluminium: *talc*, or *French chalk* (*TALCUM*, *P. G.*), also called *steatite*, having the composition $4\text{MgSiO}_3 \cdot \text{SiO}_2 \cdot 4\text{H}_2\text{O}$; *Meerschaum*, having the formula $2\text{MgO} \cdot 3\text{SiO}_2$; and several others. These minerals are insoluble, tasteless, and yield a soft, slippery powder. *Asbestos* is likewise a silicate of magnesium.

PULVIS SALICYLICUS CUM TALCO, *P. G.* An intimate mixture of finely-powdered salicylic acid 3 parts, wheat starch 10 parts, and talc 87 parts.

Uses.—The tendency of this solution to lose its water rapidly by evaporation, and then to grow hard and tough, has rendered it very convenient for making immovable bandages. It is brushed over the part, previously covered with a dry bandage, and then bandages saturated with the solution are rapidly applied in as many layers as may be necessary. The part should remain at rest for an hour to two. Owing to the risk of strangulating the limb by the contraction of the solution in drying, it has been advised to use only washed bandages, and also to apply a thin layer of carded cotton over the roller that lies next the skin. The bandage may be easily removed with scissors when it has been softened with warm water.

LIQUOR STRYCHNINÆ HYDROCHLORATIS, *Br.*—SOLUTION OF HYDROCHLORATE OF STRYCHNIA.

Liquor strychninæ.—*Soluté de strychnine*, *Fr.*; *Strychninlösung*, *G.*

Preparation.—Take of Strychnine in crystals 9 grains; Diluted Hydrochloric Acid 14 minims; Rectified Spirit $\frac{1}{2}$ fluidounce; Distilled Water $1\frac{1}{2}$ fluidounces. Mix the hydro-

chloric acid with 4 drachms of the water, and dissolve the strychnine in the mixture by the aid of heat. Then add the spirit and the remainder of the water.—*Br.*

Medical Uses.—This solution, being stable, is convenient for medical prescription. The dose is from 5 to 10 minims (*i. e.* from $\frac{1}{20}$ to $\frac{1}{10}$ grain = Gm. 0.003–0.006) of muriate of strychnia.

LIQUOR ZINCI CHLORIDI, *U. S., Br.*—SOLUTION OF CHLORIDE OF ZINC.

Chlorure de zinc liquide, Solution de Burnett, Fr.; Chlorzink-Lösung, Flüssiges Chlorzink, G.

An aqueous solution of chloride of zinc, ZnCl_2 ; mol. weight, 135.7—containing about 50 per cent. of the salt.

Preparation.—Zinc, granulated, 240 parts (2400 grains or $5\frac{1}{2}$ oz. av.); Nitric Acid 12 parts (1200 grains or $2\frac{3}{4}$ oz. av.); Precipitated Carbonate of Zinc 12 parts (120 grains); Hydrochloric Acid, Distilled Water, each a sufficient quantity; to make 1000 parts (10,000 grains or $22\frac{1}{2}$ oz. av.). To the zinc, contained in a glass or porcelain vessel, add gradually enough hydrochloric acid to dissolve it; then strain the solution, add the nitric acid, evaporate to dryness, and bring the dry mass to fusion. Let it cool, dissolve it in 150 parts (1500 grains or $3\frac{1}{4}$ fluidounces) of distilled water, add the precipitated carbonate of zinc, and agitate the mixture occasionally during 24 hours. Finally, filter through white filtering-paper free from iron, and pass enough distilled water through the filter to make the product weigh 1000 parts (10,000 grains or $22\frac{1}{2}$ oz. av. = $14\frac{1}{2}$ fluidounces).—*U. S.*

Take of granulated zinc 1 pound; hydrochloric acid 44 fluidounces; solution of chlorine a sufficiency; carbonate of zinc $\frac{1}{2}$ ounce or a sufficiency; distilled water 1 pint. Mix the hydrochloric acid and water in a porcelain dish, add the zinc, and apply a gentle heat to promote the action until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow the product to cool. Filter it into a bottle, and add solution of chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odor of chlorine. Add the carbonate of zinc in small quantities at a time and with renewed agitation until a brown sediment appears. Filter the liquid into a porcelain basin, and evaporate until it is reduced to the bulk of 2 pints.—*Br.*

Zinc dissolves in hydrochloric acid with the evolution of hydrogen gas, $\text{Zn} + 4\text{HCl}$ yields $2\text{ZnCl}_2 + 2\text{H}_2$. The iron contained in the solution is first oxidized in the one case by nitric acid, and in the other by chlorine gas. To avoid contamination with nitrate, the former solution is evaporated to dryness, redissolved in water, and then treated with zinc carbonate, whereby ferric oxide is precipitated. The process of the British Pharmacopœia arrives at the same result in a similar manner, except that an evaporation of the liquid to dryness is not necessary. 1 pound of zinc yields about $33\frac{1}{2}$ ounces of zinc chloride, which are contained in 40 (Imperial) fluidounces of the solution. Using 10 grains for each part, the formula of the *U. S. Pharmacopœia* requires 845 parts ($19\frac{1}{4}$ oz. av.) of hydrochloric acid sp. gr. 1.16, or a correspondingly larger quantity of weaker acid, and yields very nearly $11\frac{1}{2}$ oz. of dry zinc chloride and $14\frac{1}{2}$ fluidounces of the solution. The two solutions are, therefore, practically identical. The spec. grav. is stated to be 1.555 *U. S.*, 1.460 *Br.*

Properties.—The solution is a colorless and inodorous liquid which has the disagreeable metallic taste of zinc salts, and is miscible with alcohol and water without producing a precipitate. Its reactions and tests are those of *ZINCI CHLORIDUM*, which see.

The French Codex directs 1 part of fused chloride of zinc to be dissolved in 2 parts of water, the solution to be of specific gravity 1.33. Sir William Burnett's liquid contained 200 grains of zinc in the Imperial fluidounce, and was stated to have the specific gravity 2.0 and to contain about 50 per cent. of ZnCl_2 .

Medical Action and Uses.—Under the name of *Burnett's disinfecting fluid* a solution of chloride of zinc was extensively employed, and its utility probably suggested an officinal preparation for similar purposes. That solution has in numerous cases produced fatal mischief by being taken internally, occasioning all the phenomena due to a violent irritant poison, leaving in the mouth, œsophagus, and alimentary canal traces of its corrosive action, and giving the intestinal walls a leathery aspect and consistence. In some cases it is stated that the dead body showed no signs of putrefaction. The chief application of this solution is to *deodorizing* and *disinfecting* sinks, sewers, water-closets, dissecting-rooms, hospitals, etc. It has been made use of to preserve dead bodies by injecting it into the blood-vessels, but owing to its corrosive action upon steel such bodies

are not suitable for dissection. Largely diluted (gtt. x to gtt. xx in water f 3iv) (Gm. 0.60–1.30 in Gm. 120), it has been used as an injection for *gonorrhœa* in both sexes and for *leucorrhœa*; also as a collyrium in *gonorrhœal* and in *diphtheritic ophthalmia*. It should be employed, if at all, with extreme caution, the weakest solution being first applied to test the susceptibility of the parts.

LIRIODENDRON.—TULIP-TREE BARK.

White-tulip bark, E.; *Écorce de tulipier*, Fr.; *Tulpenbaurinde*, G.

The bark of *Liriodendron tulipifera*, Linné.

Nat. Ord.—Magnoliaceæ.

Origin.—The tulip tree or tulip poplar, also known as *white poplar*, *yellow poplar*, and *white wood*, is a stately tree 100 to 140 feet (30–42 M.) high, which is found in woodlands and rich soil throughout the United States from Vermont to Michigan and Eastern Kansas, and southward to the Gulf of Mexico. The trunk is from 5 to 7 feet (1.5–2 M.) in diameter, and furnishes a close-grained and light but strong wood. The leaves are alternate, petiolate, broad, three-lobed, with the terminal lobe broadest and emarginately truncate. The large flowers, which appear in May, are tulip-shaped, and have three sepals and six greenish-yellow (near the base orange-red) petals. The fruit consists of flat, indehiscent, one- or two-seeded capsules, with lance-oblong wings above, and cohering together in an elongated cone. The bark is collected from the branches and also from the trunk.

Description.—The branch-bark is in curved pieces or quills, which have a brown-gray or blackish-gray to purplish-brown outer surface marked with numerous small warts, their shallow scars or confluent lines forming more or less regular elongated meshes, which become longitudinally cleft in the older bark. The fissured, gray, corky layer is removed from the trunk-bark, which then consists exclusively of liber, has a pale-yellowish color, and a smooth very finely and closely striate inner surface. The dry bark breaks, when young, with a short, the older with a fibrous, fracture, and shows upon cross-section broad wedges of medullary rays and in the inner layers tangential rows of bast-fibres. The similar root-bark has a darker color. The slight odor of the fresh bark disappears almost completely on drying; the taste is somewhat pungently aromatic and bitter, combined with some astringency. When long kept the bark is said to become insipid; bark collected by us, and kept in a dry place for twelve years without special precaution, has still the characteristic taste in a marked degree.

Constituents.—The most important constituent appears to be the *liriodendrin* of Prof. Emmet (1831), which he obtained crystallized by concentrating the tincture made with strong alcohol, adding water until a permanent turbidity commenced to appear, and evaporating spontaneously. It forms white needles or prisms and small scales insoluble in water, soluble in alcohol and ether, fusible at about 82° C. (180° F.), and volatilizing, partly undecomposed, near 132° C. (270° F.). It is contained in the infusion of the bark and precipitated from it by an alkali. A portion is always obtained in an amorphous condition, but has the same bitter and pungent taste as the crystallized. Wallace Procter (1872) did not succeed in obtaining it crystallized by treating the alcoholic extract with petroleum benzin; it separated in transparent yellowish globules of a persistently bitter and acrid taste.

Medical Uses.—Used popularly as a domestic tonic by the country people, it was first introduced into medicine as a tonic by Dr. Benjamin Rush, who ascribed to it only the virtues of a simple bitter. Like other bitters, it has had some repute as a vermifuge and as an anti-periodic, and in warm infusion as a diuretic and sudorific. The dose of the powder is 1 or 2 drachms (Gm. 4–8). An infusion or decoction may be prepared with an ounce of the bark in a pint of water (Gm. 32 in Gm. 500), and given in the dose of 2 fluidounces (Gm. 64). A saturated tincture may be prescribed in the dose of a fluidrachm (Gm. 4).

LITHII BENZOAS, U. S.—BENZOATE OF LITHIUM.

Lithium benzoicum, *Benzoas lithicus*.—*Benzoate de lithine*, Fr.; *Lithiumbenzoat*, *Benzoesaures Lithion*, G.

Formula $\text{LiC}_7\text{H}_5\text{O}_2$. Molecular weight 128.

Preparation.—This salt is made by decomposing lithium carbonate with benzoic acid, and, according to Shuttleworth (1875), it is most advantageous to add the acid to

the carbonate. 100 grains of the latter are heated with 900 grains (2 fluidounces) of distilled water, when 330 grains of salicylic acid or a sufficient quantity of it is added in small portions until effervescence is no longer produced. The filtrate is evaporated to dryness with constant stirring, and the salt rubbed to powder, or the hot somewhat concentrated solution may be set aside to crystallize on spontaneous evaporation. The yield will be 346 grains.

Properties.—Lithium benzoate is a white salt, forming either a light crystalline powder or small glistening pearly scales, which feel greasy to the touch and are sometimes aggregated to moss-like forms. Berzelius stated the salt to be hygroscopic, but Shuttleworth, and afterward Raskowsky (1866), showed it to be permanent in the air. It has a slight odor, like that of medicinal benzoic acid, or if free from aromatic compounds is inodorous; its taste is alkaline, somewhat cooling and sweetish; its reaction to test-paper is slightly acid. It dissolves at 15° C. (59° F.) in 4 parts (Hager), 3½ parts (Shuttleworth), 3 parts (Raskowsky), of water, and in 12 parts (Hager), 10 parts (Shuttleworth), of alcohol, and at the boiling temperature in 2.5 parts (Shuttleworth), 2 parts (Raskowsky), of water, and in 10 parts of alcohol (*U. S. P.*). When heated the salt melts, and at a higher temperature emits aromatic inflammable vapors of benzol and other decomposition-products of benzoic acid, a portion of the latter subliming unaltered; the black residue left behind contains charcoal and lithium carbonate. The aqueous solution of the salt is decomposed by mineral and organic acids, but not by carbonic acid gas, and yields with ferric chloride a flesh-colored precipitate soluble in hydrochloric acid and in alcohol.

Tests.—If the benzoic acid be separated from the salt by precipitation with diluted nitric acid, and thoroughly washed, it should respond to the tests of purity mentioned under *ACIDUM BENZOICUM*. On dissolving the residue, left on ignition, in diluted hydrochloric acid, and evaporating the filtered solution to dryness, 1 part of the residue should be completely soluble in 3 parts of absolute alcohol, which, when ignited, should burn with a crimson flame, and the addition of an equal volume of stronger ether to the alcoholic solution should produce no precipitate (salts of alkalies). On dissolving another portion of the residue in a small quantity of water the solution should produce no precipitate with test solution of oxalate of ammonium (salts of alkaline earths). The aqueous solution should remain unaffected by hydrosulphuric acid or sulphide of ammonium (absence of metals).—*U. S.*

Uses.—The medicinal effects of this compound rest upon theoretical expectation rather than upon clinical observation, in so far as they depend upon the lithia it contains. In 1874, Dalkiewicz and Mallez (*Practitioner*, xiii. 274) reminded the profession of the well-known doctrine that benzoic acid is converted into hippuric acid in the system, forming soluble salts, whereas the urates of the same basis are more or less insoluble. Undoubtedly, this view explained the efficacy of benzoic acid and of the benzoate of sodium in various *calculous disorders*. Lithium was then substituted for sodium in the compound on account of its greater solubility. There is not, however, a shadow of proof that this substitution is advantageous, or that the merits of the medicine, whatever they may be, are not due to the benzoic acid it contains. So far as laboratory experiments may have weight in such a question, it should be stated that the solvent power of benzoate of lithium has been found far inferior to that of borocitrate of magnesium upon uric acid calculi (Madsen, *Bull. de thérap.*, xcviii. 68).

LITHII BROMIDUM, *U. S.*—BROMIDE OF LITHIUM.

Lithium bromatum, Bromuretum lithicum.—*Bromure de lithium*, Fr.; *Bromlithium, Lithiumbromid*, G.

Formula LiBr. Molecular weight 86.8.

Bromide of lithium should be kept in well-stopped bottles.

Preparation.—Yvon (1875) prepared the salt by dissolving lithium carbonate in hydrobromic acid and evaporating; or, 37 Gm. of the carbonate are converted into neutral sulphate, dissolved in a small portion of water, and mixed with a concentrated aqueous solution of 119 Gm. of potassium bromide; the mixture is well stirred, the liquid separated by filtration, evaporated to dryness, and treated with alcohol, which leaves potassium sulphate undissolved; the alcoholic solution is evaporated to dryness. A convenient method for preparing the salt consists in forming, first, ferrous bromide by gradually adding 399 grains of bromine to 300 grains of iron and 900 grains (2 fluidounces) of water; the green solution is filtered, heated, and in a flask agitated with 186 grains of lithium carbonate; when cool the liquid is filtered and evaporated, yielding 434 grains of

lithium bromide. Lithium bromide may be obtained in crystals by evaporating its syrupy solution over sulphuric acid. The anhydrous salt contains nearly 92 per cent. of bromine.

Properties.—Lithium bromide is a very deliquescent salt, and on this account not readily obtainable in crystals, but usually kept in the form of a white powder more or less granular. It is inodorous, and has a somewhat pungent (very sharp, *U. S. P.*) and bitterish taste and a neutral reaction. It imparts a crimson color to flame, melts at a dull red heat, and at a white heat is slowly volatilized. It is freely soluble in alcohol, also in ether, and dissolves at 0° C. (32° F.) in .7 parts, at 34° C. (93.2° F.) in .51 parts, and at 103° C. (217.4° F.) in .37 parts, of water. The concentrated, but not the largely diluted, aqueous solution yields a white precipitate with ammonium carbonate. On the addition of a few drops of chlorine-water bromine is liberated, which dissolves in carbon disulphide with a brown-yellow or yellowish-brown color, without a violet tint (absence of and difference from iodide).

Tests.—1 part of the salt should be completely soluble in 3 parts of absolute alcohol, and the addition of an equal volume of stronger ether to the alcoholic solution should produce no precipitate (salts of alkalies). On dissolving a portion of the salt in a small quantity of water, the solution should produce no precipitate with test solution of oxalate of ammonium (salts of alkaline earths). The aqueous solution should remain unaffected by hydrosulphuric acid or sulphide of ammonium (absence of metals).—*U. S.* If a solution of 0.2 Gm. of the well-dried salt be mixed with a solution of 0.4 Gm. of nitrate of silver, a yellowish precipitate is obtained, which, collected upon a filter, should be completely dissolved by much ammonia-water (absence of iodide), while the filtrate from the precipitate should not be rendered turbid by test solution of silver nitrate (absence of more than 1 per cent. of chloride).

Allied Salts.—LITHII IODIDUM, IODIDE OF LITHIUM, LiI ; mol. weight 133.6. It is obtained by dissolving lithium carbonate in hydriodic acid or by digesting a solution of iodide of calcium or iodide of iron with lithium carbonate in slight excess, filtering, and evaporating to dryness. It is a white crystalline salt, crystallizing with $3\text{H}_2\text{O}$ in deliquescent prisms, and on exposure acquires a yellow tint from liberated iodine. 1 Gm. of the dry salt requires for complete precipitation 1.27 Gm. of silver nitrate.

LITHII CHLORIDUM, CHLORIDE OF LITHIUM, LiCl ; mol. weight 42.4. The process for preparing it from lepidolite is given below. It crystallizes in anhydrous cubes or octahedrons having a saline taste and melting at a red heat, and is freely soluble in alcohol and in spirit of ether. Exposed to the atmosphere, it forms prisms or needles containing $2\text{H}_2\text{O}$, and then deliquesces; at 0° C. (32° F.) it requires 1.6 parts, at 20° C. (68° F.) 1.24 parts, and at 100° C. (212° F.) 0.77 part, of water for solution. 1 Gm. of the dry salt requires 4 Gm. of silver nitrate for complete precipitation.

Medical Action and Uses.—In 1870, Dr. S. Weir Mitchell accidentally found that bromide of lithium seemed to cause a more rapid and intense sleepiness than the other bromides. He observed, moreover, that it was the most soluble salt of its class, that it contained a larger proportion of bromine than any other, and that, clinically, it excels them all as a hypnotic, and is efficient in smaller doses than the potassium bromide as an anti-epileptic. In 1877 he declared of this salt that it stood the test of his own experience, as well as that of many French and German therapeutists, who had come to regard it as the most valuable of the bromides. According to Levy, its action, compared with that of potassium bromide, is as follows: It acts with greater force and rapidity upon the spinal cord and nerves; the anæsthesia it produces begins in the nerves and is propagated to the cord; in other words, it is a sedative of morbid excitement in the spinal cord. It does not appear to act upon the heart.

Bromide of lithium was used in the treatment of *epilepsy*, as already stated, and apparently with very remarkable advantages, but its efficiency was differently estimated by some other physicians, of whom Echeverria regarded it as inferior to the potassium bromide, and Sée prescribed it without any favorable results. The *dose* has been variously stated at from 5 to 10 grains (Gm. 0.30–0.60) and from 10 to 20 grains (Gm. 0.60–1.30), three times a day in a simple bitter infusion. But much larger doses may be prescribed. It has also been used in *gout* with no demonstrable advantage.

LITHII CARBONAS, *U. S., Br.*—CARBONATE OF LITHIUM.

Lithiæ carbonas, Lithium carbonicum, P. G.; Carbonas lithicus.—Carbonate of lithia, *E.*; Carbonate de lithine, Carbonate lithique, *F.*; Lithiumcarbonat, Kohlensaures Lithion, *G.*

Formula Li_2CO_3 . Molecular weight 74.

Origin and Preparation.—Lithium was discovered by Arfvedson (1817) in petalite and other Swedish minerals, and by Berzelius (1822) in the mineral waters of Carlsbad, Marienbad, and Franzensbrunn. It is met with as phosphate in *montebellusite* and several other minerals, and as fluoride or silicate in *lepidolite*, *spodumene*, and others. It is found in minute quantities in the ashes of some plants and in many mineral springs, often as carbonate; the waters of the Mur spring at Baden-Baden and of a hot spring at Wheel-Clifford in Cornwall are the richest known, the latter, according to W. A. Miller (1864), containing 26.05 grains LiCl in the Imperial gallon. To prepare the carbonate, lepidolite is heated with sulphuric acid; the aqueous solution, containing impure lithium sulphate, may be freed from most of the sulphates of aluminium and the alkalis by crystallizing them as alum, or it is treated with lime to separate metallic oxides and earths, and then precipitated by barium chloride to remove sulphate, and by ammonium oxalate to remove calcium. After evaporating to dryness, chloride of lithium is dissolved by a mixture of alcohol and ether, and thus freed from the chlorides of rubidium, cesium, sodium, and potassium, with which metals it is associated in the lepidolite. The concentrated aqueous solution of lithium chloride, treated with ammonium carbonate, yields a precipitate of lithium carbonate, which is washed with alcohol; the filtrate from the precipitate on being evaporated to dryness and ignited yields as chloride the lithium which had remained in solution.

Properties.—Carbonate of lithium is a light white amorphous powder or is in minute crystalline grains. It has the specific gravity 2.11, is permanent in the air, inodorous, has a mild alkaline taste and a distinct alkaline reaction, and imparts a carmine color to flame. It is insoluble in alcohol, and, according to Kremers (1856), dissolves at 13° C. (55.4° F.) in 130 parts, and at 102° C. (213.8° F.) in 128.5 parts, of water; the solution has an alkaline reaction, precipitates the salts of the heavy metals, and on boiling decomposes the ammonium salts. On heating the salt to dull redness it melts to a transparent liquid, loses a portion of its carbonic acid, and congeals on cooling to pearly oxycarbonate, which is permanent in the air; the fused salt corrodes glass, silver, and platinum. It dissolves with effervescence in dilute hydrochloric acid, and the solution, evaporated to dryness, leaves a residue of lithium chloride, which is soluble in spirit of ether, and the neutral solution of which yields a white precipitate with phosphate of sodium.

Tests.—Magnesium and calcium salts are the principal impurities: salts of heavier metals are rarely present. The salt, dissolved in nitric acid, should yield no precipitate with hydrogen sulphide either before or after neutralization with ammonia (absence of heavy metals), nor with barium nitrate (sulphate), silver nitrate (chloride), sulphuric acid (barium), nor, after neutralization, with ammonium oxalate (calcium) or lime-water (magnesium). 10 grains of the salt, neutralized with sulphuric acid and heated to redness, leave 14.86 grains of dry sulphate of lithium.—*Br.* Alkaline impurities are detected, after being converted into chlorides, by their insolubility in a mixture of equal volumes of alcohol and ether, as stated above.

Off. Prep.—Liquor lithiæ effervescens, *Br.*; Lith. citras, *U. S.*, *Br.*

Chemical Action.—When a calculus composed of uric acid and oxalate of lime is suspended in a warm solution of carbonate of lithium, it loses sensibly in weight; and when a portion of bone infiltrated with gouty concretions is placed in a solution of the salt, after two or three days the whole of the deposit disappears. In fact, the urate of lithium is the most soluble salt formed with uric acid. Garrod (*Times and Gaz.*, June, 1883, p. 691) and Jahns (*Amer. Jour. of Med. Sci.*, Jan. 1884, p. 262) show that, in laboratory experiments at least, carbonate of lithium is a much better solvent of uric acid concretions than sodium or magnesium salts. These facts have been adduced to explain the efficacy in chronic gout of numerous mineral springs in Europe and of the Gettysburg Spring in Pennsylvania.

Medical Uses.—Opinions are by no means uniform in regard to the value of carbonate of lithium in removing *uric acid deposits* and *gouty concretions*. On the one hand, it is asserted that when patients are voiding uric acid gravel it causes the deposit to diminish or to cease altogether, and that in *gout* it often diminishes the frequency of the attacks. At the same time it is stated to be powerfully diuretic. On the other hand, some authorities confidently affirm that they have seen no benefit arise from its use. Others, again, declare that it is suitable only for the treatment of chronic gout, that the daily dose of it should be small, and that its good effects become apparent only after several weeks' use. On the whole, there appears to be no substantial ground for a belief in its alleged virtues in gout and calculous diseases. Of late years sundry min-

eral waters have been vaunted as efficacious in these affections because they contained from $\frac{6}{10000}$ grain to 1 grain in a pint of the spring water. Such pretensions tend to bring the art of therapeutics into discredit.

Carbonate of lithium in solution is said to exhibit extraordinary powers in the solution of *false membrane*.

This medicine may be given in the dose of from 1 to 3 grains (Gm. 0.06–0.20) three times a day, dissolved in 3 or 4 ounces of hot water or preferably in carbonated water. Externally, it has been applied in an ointment or glycerate containing 1 part of the salt to 8 of the excipient.

LITHII CITRAS, U. S., Br.—CITRATE OF LITHIUM.

Lithiæ citras, *Lithium citricum*.—*Citrate of lithia*, E.; *Citrate de lithine*, Fr.; *Lithium-citrat*, *Citronsaures Lithion*, G.

Formula $\text{Li}_3\text{C}_6\text{H}_5\text{O}_7$. Molecular weight 210.

Citrate of lithium should be kept in well-stopped bottles.

Preparation.—Take of Carbonate of Lithia 50 grains; Citric Acid, in crystals, 90 grains; warm Distilled Water 1 fluidounce. Dissolve the citric acid in the water, and add the carbonate of lithia in successive portions, applying heat until effervescence ceases and a perfect solution is obtained. Evaporate by steam- or sand-bath until the product has a specific gravity of about 1.230, and set aside for crystals to form. Dry the crystals and preserve them in a stoppered bottle.—*Br.* Thus prepared, the salt is crystalline, and contains $4\text{H}_2\text{O}$. Molecular weight 282.

On adding lithium carbonate to a solution of citric acid, carbonic acid gas is given off and lithium carbonate remains in solution, the reaction being explained by the equation: $3\text{Li}_2\text{CO}_3 + 2\text{H}_3(\text{C}_6\text{H}_5\text{O}_7) \text{ yields } 2\text{Li}_3(\text{C}_6\text{H}_5\text{O}_7) + 3\text{CO}_2 + 3\text{H}_2\text{O}$. The yield is equal to the weight of citric acid used. The U. S. P. 1870 directed a slight excess of citric acid, while the above formula orders a slight excess of lithium carbonate, for 50 grains of the latter require 94.6 grains of the acid. For dispensing in solution the salt may well be prepared extemporaneously, the proportion of citric acid to lithium carbonate being 1000 : 528.6 (or 10 : 5.3), with a yield of 1000 (or 10) parts; on triturating in a mortar with a small quantity of hot water the decomposition is readily effected. Hager recommends precipitation of the concentrated slightly acid solution with alcohol, when the normal salt, containing 2 molecules or 14.63 per cent. of water, is precipitated.

Properties.—Lithium citrate is a white amorphous powder which dissolves in 55 parts of water (Hager), and may be obtained crystallized from a concentrated solution on standing. According to C. Umney (1876), this salt contains $4\text{H}_2\text{O}$, three of which are given off at 100°C . and the fourth molecule at 115°F .: the crystallized as well as the anhydrous salt is fairly permanent in the air, and not deliquescent, as stated by the Pharmacopœia. The salt has a neutral reaction to test-paper, is inodorous, has a saline somewhat cooling taste, is soluble in glycerin, and insoluble or nearly so in alcohol. When heated it blackens, gives off the odor of burning citric acid, inflammable gases are evolved, and finally a white residue is left, which, if neutralized with hydrochloric acid, is soluble in alcohol, and the solution, ignited, burns with a carmine color. The salt is recognized as a citrate by mixing its aqueous solution with calcium chloride, filtering if necessary, and heating the clear liquid, when a precipitate of calcium citrate will be deposited.

Tests.—Other acids besides citric are detected by their several tests. Basyous impurities are recognized by igniting some of the salt, dissolving the residue in hydrochloric acid, evaporating to dryness, and testing as described in the preceding article. “20 gr. lose at 100°C . 3.8 grs., at 115.5°C . additional 1.3 gr., and at a low red heat leave 7.8 gr. of white residue.”—*Br.* On heating a mixture of 20 grains of the salt with about 40 grains of sulphuric acid until carbonized, then evaporating to dryness and igniting, a white residue of lithium sulphate should be obtained weighing 15.7 grains.

Allied Salts.—LITHII BOROCITRAS. Edmund Scheibe (1880) has prepared three of these compounds, but regards the following two as most suitable for medicinal use. They are prepared by dissolving the ingredients in boiling water, evaporating the solution to dryness, and powdering or spreading the concentrated liquid upon glass for obtaining the salt in scales. For *lithium diborocitrate*, citric acid 20 parts, lithium carbonate 7 parts, and boric acid 12 parts are used; for *lithium monoborocitrate*, citric acid 20 parts, lithium carbonate 4 parts, and boric acid 6 parts.

Medical Action.—Like the vegetable salts of sodium and potassium, the citrate of lithium is decomposed in the body and excreted as a carbonate with the urine. Its oper-

ation is the same as that of the carbonate of lithium. Its *dose* may be stated at from 5 to 20 grains (Gm. 0.30–1.30).

LITHII SALICYLAS, U. S.—SALICYLATE OF LITHIUM.

Lithium salicylicum.—*Salicylate de lithine*, Fr.; *Lithiumsalicylat*, G.

Formula $2\text{LiC}_7\text{H}_5\text{O}_3 \cdot \text{H}_2\text{O}$. Molecular weight 306.

Preparation.—Heat a mixture of 11 parts of salicylic acid, 3 of lithium carbonate, and 25 of water until effervescence ceases; filter, wash the filter with water, evaporate, and keep in well-stopped bottles.

Properties.—The salt may be obtained crystallized in needles, but is usually met with as “a white powder, deliquescent on exposure to air, odorless or nearly so, having a sweetish taste and a faintly acid reaction; very soluble in water and alcohol. When strongly heated the salt chars, emits inflammable vapors, and finally leaves a black residue having an alkaline reaction, which imparts a crimson color to a non-luminous flame. On supersaturating the dilute aqueous solution with hydrochloric acid a bulky white precipitate is obtained which is soluble in boiling water, from which it crystallizes on cooling; also soluble in ether, and producing an intense violet color with ferric salts.”—*U. S.*

Tests.—The aqueous solution should be colorless and not effervesce on the addition of an acid (absence of carbonate). When agitated with 15 parts of concentrated sulphuric acid the salt should not impart any color to the acid within 15 minutes (absence of foreign organic matters). On dissolving the residue, left on ignition, in diluted hydrochloric acid, and evaporating the filtered solution to dryness, the residue should respond to the tests of purity mentioned for the corresponding residue under LITHII BENZOAS.—*U. S.* If 20 grains of the salt be heated with 40 grains of sulphuric acid, the mixture evaporated to dryness and ignited, a white residue of lithium sulphate should be left weighing not more than 7.2 grains.

Uses.—No evidence exists that this salt possesses any medicinal qualities that do not belong equally, if not much more decidedly, to sodium salicylate. The two salts are equally soluble in water, and there is no proof whatever that lithium salicylate displays any distinct physiological or therapeutical action. The average *dose* is variously stated at from 5 to 40 grains (Gm. 0.30–2.60). It is worthy of remark that while the U. S. Pharmacopœia contains no less than five lithium compounds, the German Pharmacopœia (1882) presents but one—the carbonate. It may well be doubted if even this one be not superfluous.

LOBELIA, U. S., Br.—LOBELIA.

Herba lobelia, P. G.—*Indian tobacco*, E.; *Herbe de lobélie enflée*, Fr.; *Lobeliënkrant*, G.

The leaves and tops of *Lobelia inflata*, *Linneé*. Barton, *Med. Bot.*, t. 16; Bentley and Trimen, *Med. Plants*, 162.

Nat. Ord.—Lobeliaceæ.

Origin.—The inflated lobelia is an annual herb, native of the North American continent, growing in dry open fields and on the borders of woods from the northern parts of Canada southward throughout the United States to Georgia and Mississippi. It flowers from July to September, and should be collected when some of the capsules have become inflated; the fresh herb, on drying, loses from 75 to 80 per cent. of moisture.

Description.—The herb grows from 12 to 20 inches (30–50 Cm.) high, and has a branching stem, which is somewhat furrowed and beset with spreading hairs. The leaves are alternate, 2 to 3 inches (50–75 Mm.) long, ovate or oblong, irregularly toothed, pubescent, and pale-green; the lower ones petiolate, the upper sessile and gradually reduced to bracts. The flowers are in long racemes, terminating the stem and branches. The calyx-tube is adherent to the ovary, has the limb divided into five narrow teeth, and becomes inflated in fruit. The pale-blue corolla is somewhat two-lipped and has the upper side of the tube split to the base. The five stamens are free from the corolla, and by the union of the filaments and anthers form a tube which encloses the single style. The fruit is a thin subglobular capsule which is two-celled, opens at the apex, and contains a large number of minute brown oblong seeds, the surface of which has, under the microscope, a reticulated appearance. It has an herbaceous somewhat irritating odor, and an herbaceous afterward burning and acrid tobacco-like taste.

Constituents.—Lobelia owes its virtues, at least in part, to an alkaloid, *lobeline*, which was first recognized by Calhoun (1833), but isolated by Procter (1838). To

obtain it, the tincture made with alcohol containing acetic acid is evaporated to a syrupy consistence, triturated with excess of magnesia, the filtrate agitated with ether, and the ethereal solution evaporated; the impure alkaloid requires purification by combining with an acid, treating with animal charcoal, and again decomposing with magnesia. W. D. Richardson (1872) obtained more alkaloid from the above mother-liquor by precipitation with potassium iodo-hydrargyrate. *Lobeline* is a yellow somewhat aromatic liquid having an acrid taste; it is lighter than water, is soluble in alcohol, ether, and fixed oils, and less so in water. Its salts, except the acetate, are crystallizable, are freely soluble in water, scarcely so in ether, and not altered by a boiling temperature, whereas the alkaloid is thereby deprived of its acrid taste. Richardson found it even to be altered by simple exposure to air, whereby it became resinified and unable to combine with acids.

Bastick (1850) considered it volatile, but to evaporate not entirely unchanged. Lewis (1878) corroborated Richardson's observations, and observed that sulphuric acid and Fröhde's reagent impart a red-brown color, and that on boiling with dilute sulphuric acid or with potassa, glucose is liberated from the alkaloid.

In 1871, Enders obtained the acrid principle *lobelacrin* by concentrating the tincture in the presence of charcoal, washing this with water, and exhausting with boiling alcohol (*Pharmacographia*). It forms warty tufts of a brown color, is soluble in ether and chloroform, slightly so in water, is decomposed by boiling with water, and yields sugar and *lobelic acid* under the influence of acids and alkalis. It is possible that the alkaloid, as heretofore obtained, has been more or less contaminated with this body, which, according to Lewis, is lobelate of lobeline.

The *lobelic acid* of Enders is probably identical with the compound of Pereira (1842), Procter, and Lewis bearing the same name. Procter obtained it from the decoction of the leaves by precipitating it with sulphate of copper and decomposing with hydrogen sulphide. It is crystallizable, soluble in ether, alcohol, and water, and yields with ferric salts an olive-brown, with copper sulphate a light-green, with lead acetate and baryta-water a yellow, and with silver nitrate a white afterward brown precipitate. The barium compound of Enders's acid is soluble in water.

Reinsch (1848) obtained from the herb also waxy, resinous, fatty, and gummy matters, and Procter from the seeds about 30 per cent. of rapidly-drying fixed oil.

Allied Species.—*LOBELIA SYPHILITICA*, Linné (*Great lobelia*). It is 2 to 3 feet (60–90 Cm.) high, has acute elliptic-oblong, irregularly-serrate leaves, and showy blue flowers in the axils of the upper leaves, forming a terminal raceme: the calyx has a short hemispherical tube, five long acute lobes, and at their base conspicuous deflexed appendages. It is met with in low grounds in the United States.

LOBELIA CARDINALIS, Linné (*Cardinal-plant*). It is common in marshy and low grounds throughout the greater portion of the United States, attains a height of 2 to 3 feet (60–90 Cm.), is nearly smooth, has oblong-lanceolate, acute, and slightly-toothed leaves, and bears long racemes of large showy scarlet-red flowers on short pedicels in the axils of the leaf-like bracts.

Off. Prep.—Acet. lobeliæ, Extract. lobeliæ fluid., *U. S.*; Tinct. lobeliæ, *U. S.*, *Br.*; Tinct. lobeliæ æther., *Br.*

Physiological Action.—The effects produced by lobelia and its alkaloid upon animals are almost identical with those of tobacco and nicotine, but larger doses are required to develop them. Lobelia is ranked as a respiratory poison, and in the cat it greatly reduces the temperature.

The symptoms caused by lobelia in man are—nausea, salivation, malaise, præcordial distress, dyspnoea and dysphagia, burning and rawness in the fauces, eructation, vomiting, urination, general muscular relaxation, profuse sweating, the pulse becoming small, irregular, and slow, and, when the dose has been very excessive, extreme prostration, anxiety, contracted pupils, insensibility, and occasionally death, preceded by convulsions.

FIG. 176.

Lobelia inflata, Linné, and section through stamens and pistil, magnified 5 diameters.

FIG. 175.

Lobelia-seed, magnified.

Many cases have been published of death from the maladministration of this drug by ignorant persons assuming to be practitioners of medicine.

Medical Uses.—The chief medicinal value of lobelia is in the treatment of *asthma*, whether the disease be purely spasmodic or associated with pulmonary emphysema, chronic bronchitis, heart disease, etc. It eliminates from the attack the bronchial spasm, which in the first-named affection constitutes the whole disease and in the others is a complication only. A fluidrachm (Gm. 4) of the tincture should be given every hour, or, if the symptoms are urgent, every half hour, until relief is obtained or the characteristic effects of the medicine are produced. Its efficacy in the other diseases mentioned, as well as in *whooping cough*, will depend mainly upon the predominance of the nervous element in them. Whenever dyspnoea is due to inflammatory changes in the bronchia, or to the presence in these tubes of secreted matters, rather than to spasm, lobelia displays special virtues that entitle it to be preferred before numerous "expectorants." It is of no more advantage in *inflammatory laryngitis* than various other nauseants and emetics, but it is decidedly more efficacious in *spasmodic laryngitis* than most other remedies of the same class. In almost all cases in which distress in breathing arises from a want of proper balance between the lungs and the heart, this medicine affords relief; as, for instance, when the lungs are congested by mitral obstruction and there is a tendency to œdema of those organs; and, again, when the lungs are themselves diseased so as to interfere with the cardiac circulation, as occasionally happens even in tuberculous consumption.

The dose of lobelia as an emetic is from 10 to 20 grains (Gm. 0.60–1.30), but for this purpose it is unnecessary, and may be dangerous. As an expectorant the dose is from 1 to 5 grains (Gm. 0.06–0.30). The preparations most frequently employed are the tincture and the vinegar of lobelia, of either of which the dose as an expectorant is from 10 to 60 minims (Gm. 0.60–4). In asthmatic attacks 1 or 2 fluidrachms (Gm. 4–8) should be administered every half hour or hour, according to the urgency of the symptoms. The dose of the fluid extract as a nauseant or expectorant is from 1 to 5 minims (Gm. 0.06–0.30).

Lobelia syphilitica was formerly used by the aborigines for the cure of syphilis, probably on account of its diaphoretic action, and at one time its virtues were maintained by several eminent physicians in Europe. They are not any longer believed in; nevertheless, there can be no doubt that, in so far as diaphoresis tends to cure syphilis, the disease may be palliated by lobelia. Older authorities describe it as being diaphoretic, and hence depurative. *L. cardinalis* possesses similar virtues, but in a less degree. It was used by the American Indians as an anthelmintic.

LOLIUM.—DARNEL.

Bearded darnel, E.; *Ivraie*, Fr.; *Lolch*, *Tauwelkorn*, G.

The fruit (caryopsis) of *Lolium temulentum*, *Linne*, s. *L. arvense*, *Withering*. Bentley and Trimen, *Med. Plants*, 295.

Nat. Ord.—Graminaceæ.

Origin.—The bearded darnel grows on waysides and in grain-fields in Western Asia and throughout Europe, and has been introduced to some extent in most grain-growing countries; it is rare in the United States. It is an annual about 2½ feet (75 Cm.) high, with rather large leaves, and has an elongated inflorescence, the spikelets being nearly an inch (25 Mm.) long, about seven-flowered, somewhat compressed, alternate, sessile, appressed to the concave rachis, and about as long as the glumes.

Description.—The fruit is oblong-ovoid, nearly ¼ inch (6 Mm.) long, enclosed in the palea, grooved on the inner and convex on the outer surface, smooth, pale-brown, internally white, inodorous, and of a farinaceous afterward bitterish taste.

Constituents.—The chemical investigations undertaken for the purpose of isolating the poisonous principle have been recently (1875) reviewed by Wittstein. The deleterious properties of the plant, according to Ludwig and Stahl (1864), appear to be due to an acrid fixed oil and to an amorphous yellowish glucoside, which is soluble in water, alcohol, and ether, and has a bitter and acrid taste. Bley (1834) and Muratori (1837) ascribed them to an acid body, and Baillet and Filhol (1863) to a non-saponifiable oily compound. Bley (1838) obtained his *lolium* by precipitating the alcoholic solution of the aqueous extract with ether; the yield was only $\frac{1}{30}$ per cent. of a dingy-white powder having an acrid taste. The fruit contains the ordinary constituents of grain, among them from 30 to 50 per cent. of starch, the granules of which, according to Schwerdt-

feger (1853), are about one-third the size of wheat starch, circular, with a moderately wide margin and a bright, strongly translucent surface without marks. On incineration, darnel-fruit leaves about 5 per cent. of ash.

LOLIUM PERENNE, *Linné*, called *ray-* or *rye-grass*, is a pasture grass, has a perennial creeping rhizome, the glumes shorter than the spikelets, and awnless or short-awned flowers. It is not poisonous.

Medical Action and Uses.—A large number of persons have at different times been poisoned by bread made with flour containing lolium. Upon different animals it acts differently: it is poisonous to dogs, sheep, and horses, but not to hogs, cows, and ducks, and quails are said to be fond of the seeds as food. Its effects have been known from ancient times to be narcotic and anæsthetic. They comprise the following symptoms: headache, vertigo, disturbed and sometimes yellow vision, ringing in the ears, paresis of the tongue, oppression in breathing, anxiety, vomiting, and sometimes purging, urination, general muscular trembling, cold sweating, and overpowering and deep sleep. In several cases the poisoning has proved fatal. There is reason to suspect that the old custom of using darnel to adulterate malt and distilled liquors is not wholly obsolete. The peculiar intoxication produced by some of these drinks strongly suggests such a fraudulent and wicked addition to them. Lolium has been mixed with poultices applied for the relief of local *pains*, pleuritic, neuralgic, and rheumatic, and, although it has been given internally, neither the grounds of its administration nor its alleged results are entitled to any confidence.

LOTIONES.—LOTIONS.

Washes, E.; *Lotions*, Fr.; *Waschungen*, G.

Lotions are liquid preparations, usually containing water as their principal vehicle, and are ordinarily applied by wetting lint or muslin with them, and keeping this upon the affected part.

LOTIO HYDRARGYRI FLAVA, *Br.*—YELLOW MERCURIAL LOTION.

Aqua phagedænica.—*Yellow wash*, E.; *Eau phagédénique*, *Eau divine de Fernel*, Fr.; *Phagedänisches Wasser*, *Altschadewasser*, G.

Preparation.—Take of Perchloride of Mercury 18 grains; Solution of Lime 10 fluidounces. Mix.—*Br.*

A double decomposition takes place, resulting in the formation of calcium chloride and finely-divided yellow mercuric oxide. It should be well shaken when used.

Surgical Action and Uses.—This preparation is stimulant, and even caustic. Its use is restricted almost exclusively to the treatment of indolent *chancres* and other *syphilitic ulcers*. It should be applied upon lint.

LOTIO HYDRARGYRI NIGRA, *Br.*—BLACK MERCURIAL LOTION.

Aqua phagedænica nigra, *Aqua nigra*, *Aqua mercurialis nigra*.—*Black wash*, E.; *Eau phagédénique noir*, Fr.; *Schwarzes Wasser*, G.

Preparation.—Take of Subchloride of Mercury 30 grains; Solution of Lime 10 fluidounces. Mix.—*Br.*

The chemical reaction between the two substances results in producing calcium chloride and black mercurous oxide. It must be well shaken when used.

Surgical Action and Uses.—The action of black wash appears to be mildly stimulant and astringent as well as protective. It may be applied on lint to *syphilitic ulcers*.

LUPINUS.—LUPIN.

Lupin, Fr.; *Feigbohne*, *Wolfsbohne*, G.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Description.—The following species, annuals, natives of Europe and Western Asia and cultivated in gardens, have been employed:

L. ALBUS, *Linné*. It has palmately five- or seven-foliolate leaves, with the leaflets obovate-oblong, 1 or 2 inches (25–50 Mm.) long, smooth above and white hairy beneath; the flowers are in terminal racemes on short pedicels, white and rather large; the legume is 3 or 4 inches (7–10 Cm.) long, flattish, and contains three to six depressed globular seeds having a bitter taste.

L. HIRSUTUS, *Linné*. It has spatulate-oblong leaflets and blue or rose-colored flowers in loose whorls, forming racemes.

L. LUTEUS, *Linné*. It is distinguished by its yellow flowers being in whorls, and these forming a dense raceme.

A large number of lupins are indigenous to the Western section and the Pacific coast of the United States, some of which, like *L. polyphyllus* and *densiflorus*, *Nuttall*, are cultivated in gardens. These, as well as the blue-flowered *L. perennis*, *Linné*, which grows in sandy soil in the Eastern portion of the United States, may possess similar properties.

Constituents.—Cassola (1835), and afterward Reinsch (1849), found the bitter principle of lupin to be insoluble in ether. Schulze and Barbieri (1878) obtained it crystalline from *Lupinus luteus* by preparing a tincture with diluted alcohol, precipitating with lead subacetate, decomposing the precipitate with sulphuretted hydrogen, and treating with hot water, on the cooling of which the bitter principle crystallizes in yellowish-white fine needles. This *lupinin*, $C_{29}H_{32}O_{16}$, is soluble in alkalis with a dark-yellow color, and on being boiled with dilute acids is split into sugar and *lupigenin*, $C_{17}H_{14}O_6$. Eichhorn (1867) obtained an alkaloid which was further investigated by Beyer, Siewert, Liebscher (1880), and Baumert (1881). *Lupinine*, $C_{21}H_{40}N_2O_{10}$, prepared from yellow lupin-seed, forms colorless rhombic prisms of a fruit-like odor and intensely bitter taste. Campani and Bettelli (1881) isolated an alkaloid from white lupin-seed. These seeds appear to contain several alkaloids.

Medical Action and Uses.—The bitterness of the seeds of *white lupin*, which render them unsuitable for food until they have been thoroughly soaked in water, seems to have increased the medicinal virtues for which the ancients esteemed them. They were bruised and applied to wounds made by venomous insects and animals, to ulcers to promote their healing, to swollen glands as discutients, and, mixed with wheaten flour, to various cutaneous affections. Internally, they were held to be stomachic, diuretic, anthelmintic, and emmenagogue. In recent times they have almost ceased to be employed in medicine, but in 1877, Donabellia (*Practitioner*, xxi. 211) reported that, having thrown into the rectum about 5 ounces of a decoction of lupins he soon began to feel general malaise, uneasiness of the head, obscuration of vision, heaviness of the eyelids, vertigo, excitement of mind, and a sense of constriction of the larynx and pharynx. Several months afterward he repeated the experiment with the same results. It is probable that this reporter used in his experiments some very different seeds from those of *white lupin*, since none of the ancient writers who treat of them at length make the least allusion to their being poisonous.

LUPULINUM, U. S., Br.—LUPULIN.

Glandulæ lupuli, P. G.; *Lupulina*, U. S. 1870.—*Lupuline*, *Lupulite*, Fr.; *Hopfenmehl*, *Lupulin*, G.

The yellow glandular powder separated from the strobiles of *Humulus Lupulus*, *Linné*. *Nat. Ord.*—*Urticaceæ*, *Cannabineæ*.

Origin.—(See *HUMULUS*, page 769). On handling dry hops the glandular powder becomes detached, and is freed from fragments of the bracts, etc. by sifting; about 10 per cent. of the weight of the hops may be obtained.

Description.—Lupulin, when fresh, is a bright, brownish-yellow, afterward yellowish-brown, granular resinous powder, which has the aromatic odor and bitter and aromatic taste of hops. Under the microscope it is seen to consist of two hemispheres, the lower and firmer of which is somewhat obtusely conical or top-shaped, the upper one rounded, the surface of both reticulate. In the dry state the lower one nearly retains its shape, but the more delicate upper part collapses and forms a flattish hood. The glands contain a brown-yellow liquid which dries up to a resinous mass. Lupulin should be free from sand, which readily subsides from it when agitated with water.

FIG. 177.

Lupulin (fresh).

Constituents.—On distilling hops with water, Personne (1854) obtained *valerianic acid* and a *volatile oil*, which boils between 140° and 300° C. (284° and 572° F.). is colorless and neutral, but becomes resinous and acid on exposure, and consists of a lighter

portion, $C_{10}H_{16}$, and *valerol*, $C_6H_{10}O$, from which by gradual oxidation valerianic acid is formed. The residue from the distillation when treated with lime yields a distillate of *valeral*, $C_5H_{10}O$. The *resin* of lupulin was examined by Vlaanderen (1858), who found it tasteless, combining with metals, and becoming more hydrated in the course of purification. The principal constituent of lupulin is wax, which Lermer (1863) found to be *myricin* (myricylic palmitate). He also isolated the bitter principle and called it *lupamaric acid* (Hopfenbittersäure). To prepare it, the ethereal extract of fresh hops is treated with 90 per cent. alcohol, which leaves the wax behind; the alcohol is evaporated, the residue dissolved in ether, and this solution agitated with strong potassa solution to remove resin; agitation with water now dissolves the potassium lupamarate, which is precipitated with copper sulphate, and the precipitate, decomposed by hydrogen sulphide, yields the acid in white crystals, becoming yellow on exposure, insoluble in water, but soluble in alcohol, ether, chloroform, carbon bisulphide, and oil of turpentine. Its composition is $C_{32}H_{50}O_7$.

Tests.—On incineration, lupulin should yield less than 10 per cent. of ash. If exhausted with ether, lupulin should leave a residue weighing not over 30 per cent., and the ethereal tincture on being evaporated at a moderate temperature should leave a brown, soft extract having the odor of hop in a high degree.”—*P. G.*

Pharmaceutical Uses.—TINCTURA LUPULINÆ, U. S. 1870. Lupulin 4 troyounces; alcohol sufficient to obtain 2 pints of tincture; prepare by percolation.

TINCTURA LUPULINÆ AMMONIATA. Lupulin 2 ounces; aromatic spirit of ammonia sufficient to obtain 1 Imperial pint (19½ fluid ounces U. S.; Dr. Dyce Duckworth, 1868.)

PILLS OF LUPULIN may be prepared by triturating lupulin with a little ether until a plastic mass is obtained, which may be incorporated with camphor or with resins or oleoresins.

Off. Prep.—Extract. lupulinæ fluid., Oleores. lupulinæ, U. S.

Medical Action and Uses.—The account given of the operation of hop (see HUMULUS) makes an extended discussion of lupulin unnecessary, since it is upon this product that the virtues of hop chiefly depend. In doses of from 20 to 25 grains (Gm. 1.30–1.60) lupulin occasions a lively sense of warmth at the epigastrium, which afterward extends to the whole abdomen. Constipation, with colicky pain, is apt to ensue, but the appetite and digestion appear to be invigorated. It is alleged that full doses of lupulin diminish the frequency of the pulse. It certainly tends to allay the susceptibility which is a frequent cause of an excited circulation. Probably in this manner, rather than by a direct action upon the brain, it favors sleep and tends to repress that excitement which occasions *priapism*, *seminal emissions*, and *nocturnal incontinence of urine*. It has seemed to allay *irritability of the bladder* when opium was not tolerated. It may be prescribed in *doses* of from 5 to 10 grains (Gm. 0.30–0.60) and upward, mixed with jelly or syrup.

LYCIUM.—MATRIMONY-VINE.

Lycium vulgare, *Dunal*, s. *L. barbarum*, *Linné*.

Nat. Ord.—Solanaceæ.

Description.—This shrub is indigenous to the countries bordering on the Mediterranean, and is cultivated and wild in the United States. It is from 10 to 20 feet (3–6 M.) high, and has numerous slender, recurved branches, which are covered with a smooth brownish-gray bark and armed with few thorns. The leaves are 1 or 2 inches (2–5 Cm.) long, alternate, oblong-lanceolate, entire, smooth, shortly petiolate, and often clustered. The greenish-purple flowers have a tubular five-lobed corolla and produce oval red two-celled berries containing many reniform seeds. The bark and leaves have a sweetish and slightly bitter and acrid taste.

Constituents.—An alkaloid, *lycine*, $C_5NH_{11}O_2$, has been isolated by Husemann and Marmé (1863) by precipitating the decoction with subacetate of lead, removing the lead by sulphuric acid, and precipitating the filtrate with phosphomolybdic acid; the precipitate is mixed with prepared chalk, the mixture dried, and the alkaloid dissolved by alcohol. It forms white prisms, which are deliquescent, sparingly soluble in ether, and have an acrid taste free from bitterness. Husemann (1875) proved it to be identical with *betaine*, an alkaloid isolated by Scheibler (1866) from beet-root juice, and, like it, not pre-existing in the plant, but formed from it during the process by the action of free acid. The leaves of *lycium* yielded a larger proportion than the branches.

Allied Species.—*Lycium Afrum*, *Linné*, of Northern Africa, and *L. umbrosum*, *Humboldt et*

Bonpland, of South America. The infusion of the leaves is used in erysipelas and skin diseases. *Berberis Lycium*, *Royle*, contains berberine (see page 315).

Medical Action and Uses.—There is nothing to establish a therapeutical character for *Lycium vulgare*, unless it be that lycine in the *dose* of 2 or 3 grains (Gr. 0.12–0.20) causes paralysis in frogs. *L. umbrosum* is said to be used in South America as a remedy for *erysipelas*, and an extract procured from *Berberis lycium* is alleged to share the qualities both of aloes and rhubarb, and to be useful when applied externally in cases requiring a stimulant and an astringent.

LYCOPERDON.—PUFF-BALL.

Lycoperdon solidum, *Gronovius*, s. *Pachyma Cocos*, *Fries*.

Nat. Ord.—Fungi, Gasteromycetes.

Origin.—This curious product is found attached to the roots of fir trees in the southern part of the United States from Virginia westward to Kansas, and is known as *Indian bread* or *tuckahoe*. It likewise grows in China, where it is used under the name of *fuh-ling*. Currey and Kelley consider it to be an altered state of the root of the tree occasioned by the presence of a fungus, the mycelium of which traverses, disintegrates, and even obliterates, the wood and bark. This view is sustained by the result of the analyses made by R. T. Brown (1871) and J. L. Keller (1876).

Description.—The tuckahoe is an irregularly globular or elongated body, varying from a few inches to a foot (30 Cm.) or more in diameter, and from a few ounces to several pounds in weight. It is externally of an ashy-black, and has a rugose surface; internally it is whitish, fissured, more or less spongy, but firm, of a somewhat farinaceous appearance, sometimes quite compact, and breaks into irregular masses. It is without odor and has an insipid taste.

Constituents.—Brown found it to contain 14 per cent. of water, 0.93 of glucose, 2.63 of gum, 17.34 of pectose, 64.45 of cellulose, and 0.16 per cent. of ash; the nitrogen amounted only to 0.36 per cent. Keller's specimen yielded 77.27 per cent. of pectose, 3.76 of cellulose, and 3.64 of ash, the other constituents being nearly in the same proportion as in the former analysis.

Allied Plants.—*Lycoperdon Bovista*, *Linne*, s. *Bovista gigantea*, *Nees*.—Common puff-ball. *E.*: Vesse-loup, *Fr.*: Bovist, *G.*—This fungus forms globular or obconical masses of a more or less yellow, or when old dark-brown, color, and varying in size from a few inches to about 2 feet (60 Cm.) in diameter. The lower part has a spongy texture, and was formerly used like spunk (see page 716) for arresting hæmorrhages.

Lycoperdon caryinum, *Linne* (*Scleroderma Persoon*), s. *Elaphomyces granulatus*, *Fries*.—Puff-ball, Hart's truffle. *E.*: Truffe de cerf, *Fr.*: Hirschbrunst, *G.*—Its size is about that of a walnut or smaller. It is brown, verrucose, internally purplish-brown, and was considered to possess stimulant properties.

Tuber cibarium, *Sibthorp* (*Lycoperdon Tuber*, *Linne*).—Truffle. *E.*: Truffe, *Fr.*: Trüffel, *G.*—It is of subterraneous growth, subglobular, about the size of a walnut, externally blackish and verrucose, internally white, marbled with brown, fleshy. Like some allied species, it is edible.

Physiological Action and Medical Uses.—In 1853, Dr. B. W. Richardson's attention having been directed to the fact that the smoke of the common *puff-ball* had been used in the country for stupefying bees in order to secure the contents of the hive without sacrificing the insects, he conceived the idea that it might be made use of as a surgical anæsthetic. He accordingly experimented upon dogs, cats, and rabbits, and in one case removed a tumor from a dog without any sign of pain being shown during the operation. When a moderate quantity was inhaled, gradually the narcotism came on and passed off slowly, the animal exhibiting all the symptoms of intoxication, with convulsions, and sometimes vomiting. It destroyed life slowly; a dog would inhale the fumes for 20 minutes or half an hour after being completely narcotized previous to expiring. The heart's beat in all cases survived the respiration. The lungs after death were pale; there was no sign of congestion in any organ: the blood retained its red color, but did not coagulate quickly; cadaveric rigidity set in within 2 or 3 hours. During recovery from protracted narcotism an animal would sometimes be quite conscious, although insensible to pain. Herapath made experiments which proved that the gas which is the active agent in producing the preceding phenomena is carbonic oxide, and his conclusion, confirmed by Snow, was accepted by Dr. Richardson. No practical application has been made of this curious discovery.

In 1869, Dr. Porcher stated concerning *L. giganteum* that it is found in abundance near

Charleston, S. C., particularly where the cattle are driven to graze. It is used sliced and fried in butter or stewed in milk like the common mushroom. A correspondent wrote to him: "I and a number of others have made several meals on *lycopodon*, and I think I have discovered in myself well-marked evidences of its narcotic influence, and two other experimenters have described similar sensations to me." A case is also referred to in which a person "had been seriously affected in this way by too large a meal of *lycopodon*." Dr. E. Thompson of Tyrone has reported its remarkable virtues as a hæmostatic, antiseptic, and anodyne dressing for *cancerous* ulcers and *bleeding wounds* (*Practitioner*, xxix. 288).

The powder of this fungus had previously been applied as a hæmostatic in slight and superficial wounds, and, like other dry absorbing powders, in *intertrigo*.

It is said to have been used as food by the Indians of the Southern States.

LYCOPODIUM, U. S., P. G.—LYCOPODIUM.

Semen lycopodii, *Pulvis lycopodii*, *Sulphur vegetabile*.—*Vegetable sulphur*, E.; *Lycopode*, *Soufre végétal*, Fr.; *Bärlappsamen*, *Streupulver*, *Hexenmehl*, *Blitzpulver*, G.

The sporules of *Lycopodium clavatum*, *Linné*, and of other species of *Lycopodium*. Bentley and Trimen, *Med. Plants*, 299.

Nat. Ord.—Lycopodiaceæ.

Origin.—The common *club-moss* is a low creeping perennial which is found in dry woods distributed over the greater portion of the globe, but is most frequent in northern countries. The stem is 2 to 4 feet (0.6–1.2 M.) long, with evergreen imbricated linear awl-shaped inflexed leaves, and with ascending very leafy branches 2 to 4 inches (5–10 Cm.) high, the fertile ones terminated by a long peduncle bearing two or three erect linear-cylindrical spikes, 1½ to 2 inches (3–5 Cm.) in length, with roundish ovate bristly-pointed bracts, in the axils of which are kidney-shaped sporangia containing the sporules. The spikes are collected before they are fully matured, and after the powder has fallen out, it is separated by a sieve from the other parts. It is collected in Germany and other countries of Central Europe.

FIG. 178.

Sporules of *Lycopodium*.

Description.—*Lycopodium* is a fine, very mobile, pale-yellowish powder which is free from odor and taste. It floats upon water, and is wetted by it with difficulty and only after continued trituration, unless it has been previously washed with alcohol, ether, or chloroform to remove a superficial layer of oily matter; after boiling it sinks in water. When triturated it acquires a darker tint, becoming more coherent and greasy; when slowly heated it burns quietly, but when thrown into a flame it burns suddenly and with a hissing noise. Examined by the microscope, it is found to be rounded on one side, while the other forms a short three-sided pyramid. The entire surface is covered by fine polyhedral meshes except at the edges of the pyramid; but at its intersection with the rounded base short projections are observed.

Constituents.—Flückiger (1872) determined the presence in *lycopodium* of a much larger amount of fixed oil than the 6 per cent. observed by Bucholz (1807), and after rupturing the granules by long trituration with sand obtained 47 per cent. of a bland oil which does not solidify at -15° C. (5° F.). Bucholz found also in it 3 per cent. of sugar. Stenhouse obtained minute quantities of volatile bases, and Flückiger determined the ash to amount to 4 per cent., to be not alkaline, and to contain alumina and 1 per cent. of phosphoric acid. The substance of the cell-wall has been called *pollenin*; on treatment with potassa it is colored yellow, and then acquires a blue color with sulphuric acid and iodine.

Impurities and Adulterations.—The sporules of allied species of *Lycopodium*, particularly of *L. complanatum*, *annotinum*, and *innundatum*, *Linné*, which are found in both hemispheres, are sometimes collected; they are very similar in appearance and properties. Mineral substances like powdered *talc*, *gypsum*, etc. are detected by the larger amount of ash, and will readily subside when a little is agitated with carbon

bisulphide or chloroform. Powdered *rosin* is detected by treatment with alcohol and evaporation of the tincture. Dextrin is soluble in water; its concentrated solution is precipitated by strong alcohol, and after having been boiled with dilute sulphuric acid it reduces red cuprous oxide from Trommer's solution. *Starch* is separated by carbon disulphide, in which it sinks, and sublimed sulphur, if present, will be dissolved by the liquid, and afterward obtained on evaporating it. Starch is also recognized by the blue color it acquires with solution of iodine. All admixtures are, however, easily detected by means of the microscope; the pollen of pine, which is sometimes found mixed with it, consists of an oval plano-convex cell, at each end of which is a smaller globular one projecting on the flat side.

FIG. 179.

Pollen of Pine.

Medical Uses.—This powder, on account of its extreme lightness and dryness, is used as a convenient protective for tender and raw surfaces of the skin in *intertrigo*, *erysipelas*, *eczema*, *herpes*, superficial *ulcers*, etc., and by druggists to place in boxes containing pills to prevent their adhering to one another. Lycopodium was formerly used as a dressing for unhealthy ulcers and in a variety of affections which required both stimulant and demulcent agents, particularly diseases of the *urinary organs* and *dysentery*. It was also given for the relief of chronic *bronchitis* and *rheumatism*. It is said (Cazin) that in Poland this powder is used upon the hair of persons affected with *plica Polonica*. But since it has been shown that this affection is not a disease, but only a result of filthiness (Kaposi), it has been cured by the free use of oil and the comb.

LYCOPUS.—BUGLEWEED.

Lycopus de Virginie, Fr.; *Virginischer Wolfsfuss*, G.

The herb of *Lycopus virginicus*, Linné.

Nat. Ord.—Labiatae, Satureieae.

Origin.—Bugleweed is a perennial herb growing in woods and shady moist places in Canada and in the United States southward to South Carolina. It flowers from July to September.

Description.—The stem is nearly smooth, about 12 to 18 inches (30–45 Cm.) high, obtusely quadrangular, and with slender runners at the base; the leaves are opposite, short-petioled, elliptic-lanceolate, toothed, wedge-shaped, and entire at the base, and glandular-punctate beneath; the flowers are small, in axillary clusters, purplish, and have a calyx with four ovate and bluntish but pointless teeth. The herb has a somewhat mint-like odor and a bitter and slightly aromatic taste.

Constituents.—The plant has most likely the general constituents of the Labiatae, prominent among which is volatile oil, some resin, and a little tannin; in this case perhaps also a bitter principle. We know of no analysis of the plant.

LYCOPUS EUROPÆUS, Linné (Water horehound, E.; *Lycopus d'Europe*, Fr.; *Wasser-andorn*, G.), has been used in Europe as *Herba marrubii aquatici*. It is indigenous to Europe and North America, and resembles the bugleweed, being mainly distinguished by the often taller, sharply four-angled stem, the more deeply and sinuate-toothed, at the base often pinnatifid, leaves, and the five triangular, sharp-pointed calyx-teeth. It varies somewhat in its foliage, and is not unfrequently collected with the preceding.

Medical Action and Uses.—Bugleweed is reputed to be astringent and sedative, to reduce the frequency of the pulse, to arrest *hemorrhage* from the lungs, to allay coughing, and to be a mild narcotic. It has been compared with digitalis. As more than half a century has elapsed since such virtues were first ascribed to it, and it still continues to be neglected and generally unknown, it may be inferred that its supposed powers were in great part imaginary. It may be used in an infusion made with $\frac{1}{2}$ ounce of the herb in a pint (Gm. 16 in Gm. 500) of boiling water. This quantity may be taken in a day.

L. europæus is said to have been used from time immemorial by the Piedmontese as a remedy for *intermittent fever*. It has also been employed to arrest passive *hemorrhages* and *mucous discharges*.

LYTHRUM.—LOOSESTRIFE.

Herba salicariæ.—Purple willow-herb, E.; *Salicaire*, Fr.; *Rother Weiderich*, G.

Lythrum Salicaria, Linné.

Nat. Ord.—Lythraceæ.

Origin.—Loosestrife is a perennial herb growing in moist places in the New England States and in Europe and Northern Asia, and is sometimes cultivated in gardens. It flowers in July and August.

Description.—The stem is angular, 3 to 5 feet (0.9–1.5 M.) high. The leaves are opposite or whorled in threes, lanceolate, sessile, clasping with the heart-shaped base, roughish downy on the lower side, about 3 inches (75 Mm.) long. The flowers are rather large, in axillary cymes, apparently whorled, form a long, interrupted, wand-like spike, and have six purple or sometimes whitish petals and twelve stamens. The herb has a mucilaginous, mildly astringent taste. The blackish-brown, branching, and fibrous root is astringent.

Constituents.—Loosestrife appears to contain mucilage and tannin as its principal constituents.

Allied Plants.—*CUPHEA VISCOSISSIMA*, Jacquin (Meehan, *Nat. Flowers*, i. p. 41), is said to have been used with advantage in diarrhoea. It is found in dry fields from the New England States westward to Illinois, and southward as far as Brazil. It is a viscidly-hairy annual, about 20 inches (50 Cm.) high, with opposite petiolate ovate-lanceolate leaves; the flowers have a somewhat inflated tubular six-toothed calyx, six unequal bluish-purple petals, and twelve included stamens.

The genus is mostly confined to tropical America, and several species are cultivated for ornament, among which the so-called *cigar-plant* (*C. platycentra*), with its scarlet-red tubular calyx, is best known. The leaves and branches of *C. antisiphilitica*, Kunth, and *C. microphylla*, Kunth, are used in South America in syphilitic complaints.

Medical Action and Uses.—Loosestrife unites in itself demulcent and astringent qualities. It has been much used in Europe in *chronic diarrhoea* and *dysentery*, *leucorrhœa*, *blenorrhœa*, and passive *hæmorrhages*, and for various local cutaneous irritations. It is generally given in a decoction prepared by boiling an ounce of the root in a pint (Gm. 32 in (Gm. 500) of water, and in doses of 1 or 2 fluidounces (Gm. 32–64).

An infusion is, however, preferable to the decoction, and may be made with half an ounce of the leaves and stems to a pint of hot water (Gm. 15 to Gm. 500) (Campardon, *Bull. de thérap.*, cv. 337).

MACIS, U. S.—MACE.

Arillus myristicæ.—*Macis*, Fr., G.; *Fleur de muscade*, Fr.; *Muskatblüthe*, G.

The arillus of the fruit of *Myristica fragrans*, Houttuyn.

Nat. Ord.—Myristicaceæ.

Origin.—(See MYRISTICA.) When the nutmeg is gathered, the arillus, which envelops the seed, is cut off and dried in the sun, whereby its bright-red color is changed to brownish-orange. With the view of its better preservation it is often sprinkled with seawater. It is principally obtained from the Banda Islands.

Description.—Mace is about $1\frac{1}{2}$ inches (38 Mm.) long, smooth, flat, about $\frac{1}{12}$ inch (2 Mm.) thick at the base, thinner above, longitudinally slit into irregular, narrow, and somewhat branching bands of a brownish-orange and nearly dull color, somewhat translucent, and fatty when pressed or scratched. It breaks readily with a short fracture, but cannot be triturated to powder on account of the oil. It has a very agreeable aromatic odor, closely analogous to that of nutmeg, and a warm aromatic taste. The United States consume annually about 80,000 pounds of mace.

Constituents.—The most important constituent is the volatile oil (*Oleum macidis*, P. G.), which is present to the amount of about 8 per cent., but occasionally as much as 17 per cent. may be obtained (*Pharmacographia*). Schacht (1862) found it to consist mainly of a hydrocarbon, $C_{10}H_{16}$, called *macene*, which yields a crystallizable compound with hydrochloric acid gas, and appears to be related to, and by Koller (1865) considered identical with, the myristicene of oil of nutmeg. The oxygenated portion of the volatile oil is still less known than the hydrocarbon. Henry (1824) found red fat soluble, and yellow fat insoluble, in alcohol, but the 24.5 per cent. residue obtained by Flückiger (*Pharmacographia*) with boiling ether and drying at 100° C. (212° F.) appeared to have consisted solely of resin and semi-resinified volatile oil. The same author obtained

with alcohol 1.04 per cent. of uncrystallizable sugar, and with hot water 1.8 per cent. of a body which turned blue, and after drying reddish-violet, with iodine, and is probably intermediate between starch and mucilage.

Adulterations are not likely to be met with, at least not of the unpowdered mace. The mace of the wild nutmeg (*M. fatua*) is of a darker red color, less divided at the base, with more slender bands, and destitute of the grateful fragrance and taste of true mace.

Pharmaceutical Preparation.—*TINCTURA MACIDIS.* Digest 1 part of mace with 5 parts of alcohol, and filter.

Medical Action and Uses.—The operation of mace appears to be the same as that of nutmeg, and there is reason to believe that an excessive dose of it may induce dangerous narcotism. It is used to impart an aromatic taste to medicines, but more commonly as a condiment for flavoring food and promoting its digestion.

MAGNESIA, U. S., Br.—MAGNESIA.

Magnesia usta, P. G.; *Magnesia calcinata*.—*Calcined magnesia*, E.; *Magnésie, Magnésie calcinée*, Fr.; *Gebrannte Magnesia*, G.

Formula MgO . Molecular weight 40.

Preparation.—Take of Carbonate of Magnesium 4 ounces. Put it into a Cornish or Hessian crucible closed loosely by a lid, and expose it to a low red heat until a small quantity, taken from the centre of the crucible when it has cooled and dropped into diluted sulphuric acid, causes no effervescence.—*Br.*

The Br. Ph. recognizes two varieties of magnesia, the heavy as *Magnesia ponderosa*, made from the heavy magnesium carbonate by the process just given, and *Magnesia levis* or *light magnesia*, which is made in precisely the same manner from the light magnesium carbonate. In the United States both kinds are extensively used, but when the heavy variety is desired it is usually designated in prescriptions as *Magnesia ponderosa*, under which title it has been admitted into the present Pharmacopœia, while the light magnesia is designated as *Magnesia*. Nearly 9000 pounds of calcined magnesia were imported into the United States in 1876, and afterward about 20,000 pounds annually.

The official carbonate of magnesium consists of magnesium carbonate and hydrate. On heating it, water and carbonic acid are given off and magnesium oxide remains behind: $4(MgCO_3) \cdot Mg_2HO \cdot 5H_2O$ yields $5MgO + 4CO_2 + 6H_2O$. The carbonate of magnesium is pressed somewhat firmly into a crucible, and this is placed in a suitable furnace, loosely covered with a lid to prevent the product from becoming contaminated with ashes and other impurities, and then heated to dull redness. The expulsion of the water and carbonic acid gas keeps the surface of the powder continually in motion, and there is no necessity of testing it as long as that motion is kept up; when the motion ceases a small quantity of the powder is taken from beneath the surface and near the centre, mixed with sufficient water to displace the air, and then poured into an excess of dilute sulphuric acid. If no evolution of carbonic acid gas takes place, the product is finished, and may be dipped out with a ladle, and the crucible filled with a fresh portion of magnesium carbonate without removing it from the furnace. Made by the process formerly recommended in the U. S. Pharmacopœia, a large and rather flat earthen vessel is used, to allow of the magnesia being stirred continuously, in which case the heat may be raised to full redness; but it should never be raised to that degree if the stirring is omitted, because the magnesia would become dense and granular, and with difficulty soluble in dilute acids. The yield is between 40 and 43 per cent. of the weight of the magnesium carbonate.

Properties.—The two varieties of magnesia have the same composition and chemical properties, and differ from each other only in the degree of aggregation of their molecules. Heavy magnesia is more readily miscible with water than the light kind, and, like the latter, should remain suspended in the water for some time, and settle gradually. Should it subside very rapidly, the probability is that it was exposed to too high a degree of heat. It may be obtained from the light variety by triturating the latter for some time in the presence of strong alcohol, drying, and rubbing to powder. Magnesia is a white, very fine powder, without odor, and of an earthy, but destitute of a saline, taste. Exposed to a high heat, it becomes more compact, but does not fuse except before the oxyhydrogen blowpipe. According to Fresenius, it requires 55,000 parts of water for solution, but the liquid, like the moistened magnesia, has a distinct alkaline reaction. Its specific gravity varies between 2.3 and 3.3. When mixed with water it unites with it, forming a hydrate having the composition Mg_2HO , and when heated losing 31 per cent.

of its weight. Exposed to the atmosphere, a similar change takes place, but carbonic acid is also absorbed and a corresponding quantity of oxycarbonate is formed. It should therefore be preserved in well-stoppered bottles. "On stirring 1 part of magnesia with 15 parts of water in a beaker, and allowing the mixture to stand for about half an hour, it will form a gelatinous mass of sufficient firmness to prevent it from falling out when the glass is inverted."—*U. S.*

Tests.—The degree of hydration allowable is not given by the pharmacopœias, but when well kept the loss by heating to redness should not exceed 5 or 6 per cent. It should dissolve in dilute acids without any or with but very slight effervescence. The absence of even traces of carbonate are demanded by the *U. S.* and British Pharmacopœias—a requirement far too stringent; the German Pharmacopœia has very properly adopted the test recommended by Biltz, and directs that if 0.2 Gm. (3 grains) of magnesia be heated to boiling with 5 Ccm. (80 minims) of water, for the purpose of expelling adherent air, and after cooling the mixture be poured into 5 Ccm. of diluted sulphuric acid, the whole of the magnesia should be dissolved, and only a small number of distinct gas-bubbles should be observed. Tested in this manner, magnesia containing 1 per cent. of carbonic acid will evolve the gas in numerous distinct bubbles, however, without foaming, and if more than traces of lime are present the liquid will be turbid and deposit calcium sulphate. When treated with dilute nitric acid, magnesia should dissolve without leaving any residue, and the solution should yield at most a faint cloudiness, but no precipitates with barium nitrate (sulphates) or silver nitrate (chlorides), and potassium ferrocyanide should impart only a bluish tint, but not a deep-blue precipitate (iron). On adding ammonium chloride and an excess of ammonia the solution should remain clear on the further addition of ammonium oxalate (absence of calcium) and on the addition of sulphhydrate of ammonium (zinc, etc.); but it yields with phosphate of sodium a copious white precipitate of ammonium-magnesium phosphate.

Several proprietary articles consisting of heavy magnesia are occasionally met with; this magnesia is generally characterized by freedom from grittiness and ready miscibility with water, but is not superior to a dense magnesia obtainable by careful manipulation from a properly-prepared magnesium carbonate.

Magnesium.—The metal magnesium is widely distributed, but is less abundant than calcium; it is found as silicate in *meerschaum*, *olivine*, *mica*, *serpentine*, and other minerals; as chloride in sea-water and the waters of saline springs; and as carbonate in most spring and mineral waters, in *magnesite*, and in *dolomite* or magnesian limestone. Black (1755) first proved magnesia to be distinct from lime, and Davy (1808) isolated the metal, which is now generally prepared by modifications of the process elaborated by St. Claire-Deville and Caron (1856), by heating sodium with anhydrous magnesium chloride; the resulting sodium chloride is dissolved by water, and the magnesium left behind in the form of a gray powder, which is fused and moulded as desired. It is a silver-white metal, of a strong metallic lustre, malleable, fusing at a red and volatilizing at a white heat, but burning with a bright white light when held in the flame of a gas-jet. Its density is only 1.78; it is not altered in dry air and but slightly tarnished in a damp atmosphere. *Soapstone* or *French chalk* is a double silicate of magnesium and aluminium.

Off. Prep.—*Massa copaihae*, *U. S.*; *Pulvis rhei comp.*, *Br.*; *Trochisci magnesiæ*, *U. S.*

Medical Action and Uses.—The action of magnesia and of its carbonates consists partly in neutralizing the acid in the alimentary canal, and partly in rendering acid secretions, as the urine, either neutral or alkaline. If a sufficient quantity of acid exists in the stomach or is attracted thither by the magnesia, a neutral purgative salt is formed; but in default of such a combination the magnesia may pass into the intestine unchanged in part, and if it be taken habitually may accumulate there and form concretions large enough to obstruct the bowel (*Bull. et Mém. de la Soc. de thérap.*, 1879, p. 77).

Magnesia has the advantage over other laxatives in being almost tasteless and in rarely causing nausea or colic. It produces feculent rather than watery stools, which are remarkable for their slight degree of fetor. It is slower than salines in its operation, but nearly as thorough. Its use is distinctly indicated in whatever condition is attended with gastro-intestinal acidity, with *heartburn*, *sour eructations*, and *flatulence*. It has even arrested the *vomiting of pregnancy* when the liquid rejected was acid. Although it corrects gastric acidity, it does not remove the cause of that symptom, for which purpose aromatics and bitter tonics are usually required. It is ordinarily associated with rhubarb in the treatment of dyspeptic *diarrhœa*, especially in children, and is a very appropriate laxative in *hemorrhoidal* cases attended with constipation. It is useful in the *aphthous* affections of the mouth which attend infantile diarrhœa. In *gout* and its allied disorders

its antacid qualities render it appropriate; the following formula is commonly employed: R. Magnesii sulph. ʒj-ij; Aquæ menthæ virid. fʒx; Vin. colchici seminis. Syrup. simpl. aa fʒj; Magnesiae ʒij.—M. S.—From 1 to 3 tablespoonfuls every 2 hours until from four to six stools are produced in the 24 hours. In infantile *colic* the following carminative mixture is used: R. Magnesiae gr. xxx; Tinct. asafetidae gtt. xl; Tinct. opii gtt. xx; Sacch. alb. gr. lx; Aquæ fʒj.—M. S.—20 drops and upward every hour until relief occurs. Magnesia is appropriate, as already stated, in cases of *uric acid gravel*, but is probably less so than the carbonates of sodium and potassium; but in such cases, when marked by gastric acidity, it should not be neglected. Like its carbonate, magnesia taken internally will sometimes entirely remove *warts*. Dujardin-Beaumetz has reported a striking example of the efficacy of this treatment (*Bull. de thérap.*, civ. 232).

As an antidote to *arsenious acid* freshly-precipitated magnesia ranks next in value to freshly-prepared sesquioxide of iron. It is also antidotal to *acids*, including oxalic acid, and to *phosphorus*. In all cases of poisoning for which it is appropriate magnesia should be very largely administered, diffused in water.

As a purgative the dose of magnesia is about 40 grains (Gm. 3), and 5 grains (Gm. 0.30) for infants. As an antacid it may be taken in doses of 10 grains (Gm. 0.60) after meals, suspended in water. Mixture with milk, which is usual to disguise its taste, renders its operation slower.

The medicinal action and uses of Magnesia ponderosa are identical with those of magnesia.

MAGNESII CARBONAS, U. S.—CARBONATE OF MAGNESIUM.

Magnesie carbonas, Magnesium carbonicum, P. G.; *Magnesia alba, Magnesia hydricarbonica, Carbonas magnesicis*.—*Carbonate of magnesia*, E.; *Carbonate de magnésie, Magnésie blanche*, Fr.; *Magnesiumkarbonat, Weisse Magnesia*, G.

Formula $(\text{MgCO}_3)_4 \cdot \text{Mg}(\text{HO})_2 \cdot 5\text{H}_2\text{O}$. Molecular weight 484.

Preparation.—Take of Sulphate of Magnesia 10 ounces; Carbonate of Soda 12 ounces; Boiling Distilled Water a sufficiency. Dissolve the sulphate of magnesia and the carbonate of soda each in a pint of the water, mix the two solutions, and evaporate the whole to perfect dryness by means of a sand-bath. Digest the residue for half an hour with 2 pints of the water, and, having collected the insoluble matter on a calico filter, wash it repeatedly with distilled water until the washings cease to give a precipitate with chloride of barium. Finally, dry the product at a temperature not exceeding 212°F .—Br.

This process yields *Magnesii carbonas ponderosa*, Br.; if the two solutions are mixed and then boiled for 10 or 15 minutes, but not evaporated, the precipitate will be more bulky, and after washing and drying constitutes the *Magnesii carbonas levis* or *light carbonate of magnesium* of the British Pharmacopœia.

On mixing cold solutions of magnesium sulphate and sodium carbonate a white voluminous precipitate results, which in the course of several days is gradually converted into the compound $\text{Mg}(\text{CO}_3)_3 \cdot 3\text{H}_2\text{O}$, identical with that which often crystallizes from the effervescing solution of magnesia (see p. 911); but when heat is applied carbonic acid gas is given off, and the insoluble portion remaining is a hydrocarbonate, the composition of which varies somewhat, a larger amount of carbonic acid being given off if the heat be continued; and the heavy magnesium carbonate obtained as described above has probably the formula determined by Berzelius, $3\text{MgCO}_3 \cdot \text{MgH}_2\text{O}_2 \cdot 3\text{H}_2\text{O}$; which compound on ignition would yield nearly 44 per cent. of magnesia, MgO , as required by the British Pharmacopœia. Light magnesium carbonate yields less (between 40.3 and 41.7 per cent.) magnesia, according to Otto and Laake. The formula $3\text{MgOCO}_3 \cdot \text{MgH}_2\text{O}_2 \cdot 4\text{H}_2\text{O}$ requires 41.9 per cent. MgO . A compound of the composition $4\text{MgOCO}_3 \cdot \text{MgH}_2\text{O}_2 \cdot 5\text{H}_2\text{O}$ would yield 41.3, and with an additional H_2O only 40. per cent. MgO . Magnesium carbonate may be obtained from the mother-liquors or bitters of salt-works, and is prepared on an extensive scale in England from magnesian limestone by treating it in the state of powder with cold water and carbonic acid under a pressure of five or six atmospheres; magnesium bicarbonate is first dissolved, removed from the calcium salt, and by boiling converted into the officinal carbonate. The importation of magnesium carbonate into the United States increased from 134,000 pounds in 1867 to 355,447 in 1878, but since that time has been less.

Properties.—Besides the slight difference in composition just referred to, the heavy and light magnesium carbonates differ only in the degree of aggregation of their mole-

cules, the former being slightly granular, the latter a smooth and less dense powder, both being inodorous and of a slight earthy taste. It is almost insoluble in water, requiring, according to Fyfe, 2500 parts of cold and 9000 parts of boiling water for solution, and when it is moistened with water and applied to turmeric-paper a brown color is gradually produced. When heated to dull redness water and carbonic acid gas are given off and magnesia remains. It dissolves with copious effervescence in dilute sulphuric, hydrochloric, and other acids, and the solutions have the chemical behavior of magnesium salts.

Tests.—Magnesium carbonate may be contaminated with calcium compound, and from incomplete washing also with the acidulous radicals contained in the mother-liquors, more particularly with chlorides, bromides, and sulphates. These impurities are detected by dissolving the carbonate in dilute nitric acid, and this solution should not be precipitated by nitrate of silver (chloride and bromide) or barium nitrate (sulphate); neutralized with ammonia, it should not be precipitated by ammonium oxalate (calcium). On the addition of ammonia or ammonium carbonate a white precipitate is produced, which should be completely soluble in an excess of the precipitant and in ammonium chloride (an insoluble portion would indicate alumina), and the ammoniacal solution should not yield a white precipitate with hydrogen sulphide (zinc).

The following tests have been adopted by the German and United States Pharmacopœias: Distilled water, boiled with the salt, and after filtration evaporated to dryness, should not leave more than a trace of a fixed residue. The salt should be soluble in diluted hydrochloric acid to a colorless liquid. A 2 per cent. solution of the salt prepared with the aid of acetic acid should not be affected with hydrosulphuric (not hydrochloric, as stated by the U. S. P.) acid, nor, after addition of test solution of carbonate (chloride, *P. G.*) of ammonium with an excess of water of ammonia, by solution of sulphide of ammonium (absence of metals). Another portion of the 2 per cent. solution should not at once (within two minutes, *P. G.*) be rendered more than faintly opalescent by test solution of nitrate of barium (limit of sulphate) or of nitrate of silver (chloride). The cold solution in hydrochloric acid, on being supersaturated with test solution of ammonium carbonate, should not be rendered more than faintly opalescent (absence of more than traces of aluminium or calcium).—*U. S.* If 0.2 Gm. of magnesium carbonate with 2 Ccm. of water and 8 or 9 drops of hydrochloric acid be heated to boiling, and the solution then mixed with 10 Ccm. of test solution of ammonium chloride, 20 Ccm. of distilled water, 5 Ccm. of ammonia, and 6 Ccm. of test solution of ammonium oxalate, the liquid should not at once become turbid (calcium).—*P. G.* Iron, if present, is removed either by precipitating it from the solution with lime, or by calcining the salt, when insoluble ferric oxide is formed.

Off. Prep.—Liquor magnes. carbon.. *Br.*; Liq. magnes. citrat., *U. S.*; *Br.*; Magnesia, *Br.*; Magnes. citras granulatus, *Mistura magnesiae et asafœtidæ, U. S.*; *Trochisci bismuthi, Br.*

Medical Uses.—The carbonate is less efficient than magnesia itself, but its action and uses are the same. It is said to remove warts from the skin when taken night and morning in teaspoonful doses and continued for several weeks.

Carbonate of magnesium may be given as a laxative in doses of from 30 to 120 grains (Gm. 2–8); as an antacid from 5 to 20 grains (Gm. 0.30–1.30) may be taken after meals. It may be agreeably administered in carbonic acid water.

MAGNESII CITRAS GRANULATUS, *U. S.*—GRANULATED CITRATE OF MAGNESIUM.

Magnesium citricum effervesces, P. G.—*Effervescing magnesium citrate, E.*; *Limonade sèche au citrate de magnésie, Fr.*; *Brausemagnesia, Magnesiumcitrat in Körnern, G.*

Preparation.—Carbonate of Magnesium 11 parts (2½ oz. av.); Citric Acid 48 parts (12 oz. av.); Bicarbonate of Sodium 37 parts (9¼ oz. av.); Sugar, in No 60 powder, 8 parts (2 oz. av.); Alcohol, Distilled Water, each a sufficient quantity; to make 100 parts (25 oz. av.). Mix the carbonate of magnesium intimately with 33 parts (8¼ oz. av.) of citric acid, and enough distilled water (about 5 parts or 1¼ fluidounces) to make a thick paste; dry this at a temperature not exceeding 30° C. (86° F.), and reduce it to a fine powder. Then mix it intimately with the sugar, the bicarbonate of sodium, and the remainder of the citric acid (15 parts or 3¾ oz. av.), previously reduced to a very fine powder. Dampen the mass with a sufficient quantity of alcohol, and rub it through a No. 20 tinned-iron sieve, to form a coarse granular powder. Lastly, dry it in a mode-

ately warm place. Granulated citrate of magnesium should be kept in well-closed bottles.—*U. S.*

The formula of the German Pharmacopœia is like the preceding except in the second part, where, calculated for the above proportion of magnesium carbonate, 37.4 parts of sodium bicarbonate, 17.4 parts of citric acid, and 8.7 parts of sugar are directed. The French Codex uses calcined magnesia 65, magnesium carbonate 60, citric acid 300, and sugar 600, parts.

The first step is the preparation at as low a temperature as possible of an acid magnesium citrate, a little over one-half the citric acid ordered for this manipulation being sufficient for the formation of the normal salt. The remaining operation has for its object the incorporation with this salt of sodium bicarbonate and citric acid in such a manner as to avoid mutual decomposition, which is designed to take place only when the mixture is to be used and is stirred with water. Sieves of different degrees of fineness are usually used, so as to obtain granules nearly uniform in size.

Properties.—This preparation forms white granules or a white granular inodorous powder having an acid reaction and a pleasantly saline and mildly acidulous refreshing taste. On exposure to the air it attracts moisture, resulting in the decomposition of the bicarbonate and the evolution of carbonic acid gas, and afterward becomes damp, without, however, completely deliquescing. It is nearly insoluble, or rather only partly soluble, in alcohol, but dissolves slowly and with copious, long-continued but not vehement effervescence in 2 parts of water at 15° C. (59° F.); this solution is rarely perfectly clear, but usually is more or less opalescent from traces of impurities contained in the magnesium carbonate, and in the course of several days deposits crystals of magnesium citrate. Boiling water dissolves more rapidly a larger amount of the granules, and this solution separates on cooling a portion of the magnesium citrate in crystals. The total amount of citric acid ordered by the U. S. Pharmacopœia is only slightly in excess of that required for the production of normal salts: an increase from 48 to 49 or 50 parts would render the taste more acidulous and the solution more permanent. The aqueous solution shows the reactions of citric acid and of magnesium salts; on boiling with test solution of calcium chloride a white precipitate is produced, and the cold solution, on being rendered alkaline with ammonia-water, yields with test solution of sodium or ammonium phosphate a white precipitate which is readily soluble in acetic acid.

Tests.—“The saturated aqueous solution of the salt, when mixed with a saturated solution of acetate of potassium and some acetic acid, should not yield a white crystalline precipitate (absence of tartrate).”—*U. S.* A solution of 1 Gm. of the granules, on being treated with ammonia-water and ammonium phosphate, should yield a precipitate, which, after having been thoroughly washed with diluted ammonia-water, then dried, and ignited in a porcelain crucible, should leave a white residue of magnesium pyrophosphate weighing not less than 1.22 Gm., showing the presence of at least 4.4 per cent. of MgO.

Uses.—In the dose of from 120 grains to an ounce (Gm. 8–30) this compound forms an agreeable laxative in mild febrile disorders.

MAGNESII SULPHAS, *U. S., Br.*—SULPHATE OF MAGNESIUM.

Magnesiæ sulphas, Magnesium sulfuricum, P. G.; Sal amarum, Sal Epsomense, Sal anglicum, Sal Sedlicense, Sulfas magnesiæ.—*Sulphate of magnesia, Epsom salt, E.; Sulfate de magnésie, Sel d'Epsom, Sel de Sedlitz, Sel gmer, Fr.; Magnesiumsulfat, Bittersalz, Schwefelsaures Magnesium, G.*

Formula $MgSO_4 \cdot 7H_2O$. Molecular weight 246.

Origin and Preparation.—Sulphate of magnesium is contained in sea-water and in the waters of many mineral springs, which thereby acquire a bitter taste. The *Crab Orchard salt* of Kentucky is the same salt in an impure state, and, as analyzed by J. T. Viley (1871), contains about 65 per cent. of magnesium sulphate after having been dried at 120° C. It probably results from the mutual decomposition of gypsum and magnesian limestone, and is obtained by evaporating the water which collects in wells dug in the ground. The pure salt is made on the large scale from *magnesite*, which is principally $MgCO_3$, by dissolving it in dilute sulphuric acid and crystallizing: large quantities of the salt are made by various processes from magnesian limestone, and more recently it is extensively obtained at the Stassfurt salt-works, principally from the mineral *kieserite*, which is $MgSO_4$ combined with varying quantities of water, and in its natural state as insoluble as gypsum. 37,542 pounds of this salt were imported in 1878, and 9422 pounds in 1882.

Properties.—As found in the market, magnesium sulphate has generally been purified by re-resolution in water and rapid crystallization, and forms small rhombic prisms or needles, which resemble those of oxalic acid and sulphate of zinc, are perfectly transparent, without odor, and have a cooling and bitter saline taste and a neutral reaction. It dissolves at the ordinary temperature in from one to one and a half times its weight, and in two-thirds its own weight of boiling water; it is also soluble in diluted alcohol, but insoluble in strong alcohol. Both the German and U. S. Pharmacopœias give the solubility of crystallized magnesium sulphate as 1 part in 0.8 parts of water at 15° C., and in 0.15 parts of boiling water; but a solution saturated at 15° C. contains for 100 parts of water, according to Mulder (1864), 69.29 parts; according to Gerlach (1859), 107.1 parts; and according to Michel and Krafft (1854), 108.44 parts; and at 100° C., according to Mulder, 151.29 parts of the crystallized salt. Exposed to air, the crystals slowly effloresce, becoming superficially opaque; when heated the salt melts, gives off $6\text{H}_2\text{O} = 43.9$ per cent., and at a red heat parts with the last molecule of water, fuses, and on cooling congeals into a white mass weighing 48.78 per cent. of the crystallized salt; the total weight of water amounts to 51.22 per cent. The aqueous solution on the addition of barium chloride yields a white precipitate of barium sulphate insoluble in hydrochloric acid. It is not precipitated in the cold by potassium bicarbonate or ammonium carbonate, but gives white precipitates with the carbonates and the hydrates of sodium and potassium, which are redissolved by ammonium chloride. Ammonia added to its solution likewise causes a white precipitate soluble in ammonium chloride, and this solution, on the addition of ammonium phosphate, deposits all magnesium in the form of a crystalline powder, which is phosphate of magnesium and ammonium, $\text{MgNH}_4\text{PO}_4 \cdot 6\text{H}_2\text{O}$, and is insoluble in diluted ammonia, sparingly soluble in water, and freely soluble in diluted acetic and other acids; the precipitate, after having been well washed with diluted ammonia, then dried, and ignited in a porcelain crucible, is converted into magnesium pyrophosphate, $\text{Mg}_2\text{P}_2\text{O}_7$ (mol. weight 222), which represents 21.62 per cent. Mg or 36.03 per cent. of MgO .

Tests.—Impurities are detected in precisely the same manner as in the nitric acid solution of magnesium carbonate (see above). The following tests have been adopted by the U. S. P.: "The aqueous solution should not be colored nor be precipitated by test solution of ferrocyanide of potassium, hydrosulphuric acid, or sulphide of ammonium (absence of metals). A 5 per cent. solution, after addition of chloride of ammonium, should not be precipitated nor rendered turbid by test solution of carbonate of ammonium and water of ammonia (absence of other alkaline earths). A 1 per cent. solution should not yield more than a slight opalescence with test solution of nitrate of silver (limit of chloride). If an aqueous solution of 1 Gm. of the salt, mixed with chloride of ammonium, be completely precipitated by solution of phosphate of ammonium and water of ammonia, the filtrate evaporated to dryness, the residue gently ignited and then dissolved in 5 Cem. of water, this solution, acidulated with a few drops of hydrochloric acid, should not become more than faintly opalescent on mixing 1 volume of it with 2 volumes of alcohol nor on adding test solution of chloride of barium to another portion (absence of more than about 1 per cent. of sulphates of alkalis)."

The test for alkaline earths in magnesium sulphate is superfluous, their sulphates being insoluble, or sparingly soluble, in water. The simpler tests of the German Pharmacopœia are as follows: "A 5 per cent. solution should have a neutral reaction; it should not be affected by hydrogen sulphide after having been acidulated with acetic acid, nor by ammonium chloride and ammonia and the subsequent addition of ammonium sulphide; tested with silver nitrate, it should at most become opalescent within 5 minutes. The salt while being held in a flame should not persistently color it yellow."

Pharmaceutical Uses.—Sulphate of magnesium is used for preparing Magnes. carbon. and Liquor magnes. carbon., and forms a constituent of Infusum sennæ comp., U. S.; Enema magnes. sulphat. and Mistura sennæ comp., Br.

MAGNESII SULPHAS EXSICCATUS, Magnesium sulphuricum siccum, P. G. The crystallized sulphate is exposed in a warm place until it has lost from 35 to 37 per cent. of its weight, and is then passed through a sieve. It is a white powder having the properties of the crystallized salt, except that it contains less water; on exposure to air it gradually attracts moisture, and should therefore be kept in well-stopped bottles. The

FIG. 180.

Crystal of Magnesium Sulphate.

German Pharmacopœia directs it to be dispensed when powdered magnesium sulphate is prescribed.

MAGNESII LACTAS, Lactate of magnesium, $\text{Mg}_2(\text{C}_3\text{H}_5\text{O}_3)_3 \cdot 3\text{H}_2\text{O}$; mol. weight 256. 6 parts of calcium lactate (see page 71) and 5 parts of magnesium sulphate are separately dissolved in hot water, the solutions mixed and filtered from the precipitated calcium sulphate, the last traces of which are removed by digesting with a little magnesium carbonate; the filtrate is then evaporated and crystallized. The salt forms white granular crystals or needles, is insoluble in alcohol, soluble in about 30 parts of cold and 6 parts of boiling water, and when heated is decomposed without melting. Its solution in water is not precipitated by nitrate of barium, carbonate of ammonium, or sulphhydrate of ammonium.

Medical Action and Uses.—Sulphate of magnesium, dissolved in a large quantity of water and taken on an empty stomach, is very prompt in its operation, producing copious watery dejections and generally diuresis. Indeed, if the skin be kept cool the latter mode of operation may exceed the purgative effect, particularly if the dose be not large. Delicate persons, especially in cool weather, are apt to feel chilly and weak during its operation. This refrigerant influence renders it appropriate in warm weather and in febrile affections. If the dose be excessive and largely diluted, hypercatharsis may occur. On the other hand, large doses not thus diluted have sometimes occasioned an alarming sedation, with pallor, debility, coldness, and even syncope, although no purgation whatever occurred. In at least one case, that of a boy ten years old, death resulted. These effects, according to the dose and degree of dilution with water, are more or less produced by all saline cathartics. According to Rutherford, magnesium sulphate has no cholagogue action. Iaworski finds that a solution of sulphate of sodium is much more rapidly absorbed from the stomach than one of magnesium sulphate (*Bull. de thérap.*, vi. 228).

When properly administered it is nearly always a safe and harmless purgative; indeed, it is generally used without medical advice by persons affected with *constipation*, slight *febrile attacks*, etc. It is highly objectionable when habitually employed for the former purpose in a full purgative dose, for it soon ceases to act purgatively and confirms the evil it was used to cure. It is also one of the least eligible cathartics in cold weather. On the other hand, if used in small doses largely diluted, as 1 drachm in $\frac{1}{2}$ pint of water, it may be continued for a long time without sensibly diminishing in activity. As an anti-phlogistic purgative at the commencement of *fevers*, especially of malarial fevers, it is justly esteemed, whether or not it is preceded by a dose of $\frac{1}{8}$ or 10 grains of calomel, which many think essential to the result. In *typhoid fever* there is much reason to believe that a gentle purgative action maintained during the first week of the attack by this medicine tends to moderate the fever, mitigate the special typhoid phenomena of the disease, and lessen the danger of intestinal perforation. In acute *dysentery* of a sthenic type saline laxatives, and this one among the number, have a decided influence in lessening the tormina, tenesmus, and bloody and mucous stools, and reducing the febrile action. But to be efficient its administration ought to commence as early as possible in the attack and before ulcers form in the rectum. In both of the last-mentioned affections an ounce of the salt may be dissolved in a pint of water, and a wine-glassful of the solution administered every two or three hours. When this treatment has been pursued for 24 or 48 hours it should be suspended for about 12 hours, and then resumed. In various *inflammations*, serous and parenchymatous, it was formerly the custom to administer Epsom salt in small doses, largely diluted, with the addition of half a grain of tartar emetic to each pint of the solution, which was given in wine-glassful doses at intervals of 3 hours. The method is temporarily supplanted by the use of medicines which reduce the pulse-rate and temperature without providing any outlet for the effete products of morbid action.

In all cases of *intestinal obstruction* not clearly due to organic causes the use of this or some similar medicine should have a fair trial, care being taken to employ a weak solution and to administer it in moderate doses at proper intervals. In *painter's colic* sulphate of magnesium with the addition of sulphuric acid has been regarded as a specific for the disease, but erroneously.

Administration.—From half an ounce to an ounce (Gm. 16–32) of Epsom salt dissolved in half a pint (Gm. 250) of water is a full purgative dose, but even a less proportion of the salt and a larger proportion of water will produce nearly an equal effect. Its taste may be partially disguised by aromatic sulphuric acid in the proportion of half a fluidrachm to the half pint of liquid. The addition to the saline solution of a little strong

coffee helps to mask its nauseous flavor. It is frequently given in an infusion of senna when a prompt and vigorous operation is required. This mixture forms the basis of the so-called "black draught."

MAGNESII SULPHIS, U. S.—SULPHITE OF MAGNESIUM.

Magnesium sulfurosum, Sulphis magnesicus.—*Sulfite de magnésic, Fr.; Magnesiumsulfît, Schweffligsaures Magnesium, G.*

Formula $MgSO_3 \cdot 6H_2O$. Molecular weight 212.

Preparation.—G. Archbold (1872) recommended its preparation by passing sulphurous acid gas in excess through a mixture of magnesium carbonate and water and carefully concentrating the solution. Prof. Remington (1878) suspends 1 part of magnesia in 2 parts of water, and adds an excess of officinal sulphurous acid. Hager's process is as follows: Mix 1 part of magnesium carbonate with 8 parts of water, and pass into the mixture, stirring it occasionally, a current of sulphurous acid gas as long as carbonic acid gas is evolved and until the liquid rapidly bleaches litmus; the delivery-tube should terminate about an inch (25 Mm.) beneath the surface of the liquid. The mixture, containing an excess of sulphurous acid, is set aside for several hours, the clear liquid decanted, the crystalline magma washed with water, drained, and dried in a moderately warm place. The yield is 2 parts. According to R. H. Davies (1872), an acid sulphite is not formed.

Magnesium sulphite should be kept in well-stopped small bottles; in contact with air it is converted into sulphate.

Properties.—The salt is a white crystalline, inodorous powder, having an earthy, somewhat bitter, and sulphurous taste and a neutral or slightly alkaline reaction; it may be obtained in colorless tetrahedrons (Fourcroy and Vauquelin), or in hexagonal rhombohedrons (Rammelsberg), which on exposure to air become opaque from the formation of sulphate. The salt is insoluble in alcohol. Fourcroy and Vauquelin state that it dissolves in 20 parts of water at 15° C. (59° F.) and in less (19 parts *U. S. P.*) of boiling water; according to Hager, 80 parts of cold and 120 parts of boiling water are necessary for solution. At about 200° C. (392° F.) the salt becomes soft and parts with its water of crystallization, and at a higher heat is converted into magnesia and anhydrous magnesium sulphate. The aqueous solution shows with alkali carbonates or phosphates the same behavior as the sulphate.

Tests.—"When treated with four times its weight of diluted hydrochloric acid the salt dissolves completely and emits the odor of burning sulphur, without becoming cloudy (difference from hyposulphite). A 1 per cent. aqueous solution, strongly acidulated with hydrochloric acid, should not afford more than a slight cloudiness with test solution of chloride of barium (limit of sulphate)."—*U. S.* Hager suggests the following: A solution of 1 Gm. of the salt in 100 Gm. of water on being mixed with a solution of 1 Gm. of iodine in test solution of potassium iodide, and afterward with 5 Gm. of diluted sulphuric acid, should form a clear and colorless liquid; 1 part of pure magnesium sulphite will decolorize 1.19 parts of iodine.

Uses.—This compound appears to be identical in its action with sulphite of sodium. It tends to check fermentation, and hence to arrest the formation of gases in the alimentary canal during digestion. It appears to be a superfluous addition to the Pharmacopœia. It may be given in *doses* of from 10 to 60 grains (Gm. 0.60–2).

MAGNOLIA, U. S.—MAGNOLIA.

Magnolia-bark, E.; Écorce de magnolier, Fr.; Magnolienrinde, G.

The bark of *Magnolia glauca*, *Magnolia acuminata*, and *Magnolia tripetala*, *Linné* (*M. Umbrella, Lamarek*).

Nat. Ord.—Magnoliaceæ.

Origin.—*M. glauca*, *sweet bay, white bay, beaver tree*, or *swamp sassafras*, is indigenous to swampy localities near the coast of the United States from Massachusetts to Louisiana; in the northern part of the country it is shrubby; farther south it is a small tree 15 to 25 feet (4.5–7.5 M.) high. It has oval-oblong leaves, which are shining above and white beneath, and bears fragrant white flowers about 2 inches (5 Cm.) in diameter, with about ten ovate or obovate-obtuse petals. The leaves may be used for marking by placing the white surface upon the fabric and writing with some pressure upon the upper surface: the roots yield a yellow dye.

M. acuminata, called *cucumber tree* from the appearance of the young fruit, is found in groves and rich woods from Western New York to Ohio and southward, chiefly along the Alleghanies to Georgia, and westward to Tennessee. It grows to the height of 60 to 90 feet (18-27 M.), and has oblong-acuminate, underneath pubescent, leaves, and light bluish-green flowers tinged with yellow, about 4 or 5 inches (10-13 Cm.) in diameter.

M. Umbrella, *umbrella tree*, so called from the large leaves appearing whorled at the ends of the branches, is found in rich soil from Pennsylvania and Ohio southward along the Alleghanies to Georgia and Tennessee, and attains a height of about 40 feet (12 M.). Its leaves are over a foot, sometimes 3 feet (30-90 Cm.), long, obovate-lanceolate, pointed at both ends, silky when young, and its white flowers are about 7 inches (18 Cm.) in diameter.

The magnolias produce their flowers in May and June; they have a white or greenish calyx of three sepals, many stamens with short filaments, and many ovaries collected on an elongated receptacle, forming a cone-like aggregation of fruits which open at maturity, the berry-like seeds being suspended by a thread-like funiculus.

Description.—The bark necessarily varies as obtained from the different species. The young bark of *M. glauca* is light orange-brown, glossy, with some gray spots, and underneath the thin corky layer of a green color. The bark of the larger branches is nearly smooth, externally of a light-gray or whitish color, marked with scattered warts and some longitudinal cracks. Older bark has the warts somewhat confluent and the cracks deepened into fissures. The inner surface is whitish, or, after drying, yellowish or pale-brownish, smooth, and very finely and closely striate. The bark of *M. tripetala* is thicker, is of a pale-brown underneath the ash-gray outer layer, and has a thick liber with rather tough bast-fibres. Magnolia-bark breaks in the outer layer with a smooth fracture, and with a more or less fibrous fracture in the bast-layer, and exhibits upon the light-brownish transverse section rather broad wedges of the bast and medullary rays. The dried bark has scarcely any odor, but its taste is warm, spicy, somewhat astringent, and bitter, particularly in the young bark.

Constituents.—The bark of *Magnolia grandiflora* was examined by Stephen Procter (1842), who found in it a little volatile oil, resin, and a crystalline principle resembling liriodendrin. The root- and stem-bark of *M. glauca* were investigated by W. D. Harrison (1862), the former yielding a little volatile oil and nearly tasteless and colorless crystals; the latter contained tannin, producing a dark-green precipitate with ferric salts, but did not yield the crystalline principle nor could the bitter principle be isolated. By treating the alcoholic extract of the fruit of *M. Umbrella* with hot petroleum benzin, Wallace Procter (1872) obtained colorless crystals of *magnolin*, which are soluble in alkalies, alcohol, ether, chloroform, carbon bisulphide, and fixed oils, but sparingly so in boiling water, in which they fuse; the solutions have an irritating taste. The crystals are colored red by sulphuric acid and brown by nitric acid. The pungent taste of the fruit is due to a soft resin and the odor to a little volatile oil.

Medical Uses.—The bark of the several medicinal species of magnolia is bitter and aromatic without astringency. Like numerous other plants of similar qualities, it has been used in hot decoction to produce diaphoresis in *fevers*, bronchial *catarrhs*, *rheumatism*, and *gout*, and in cold decoction or tincture as a tonic. The tree is said to render clear the waters near which it grows, and to prevent malarial affections. The preparations of the bark spoken of above are used in the cure of intermittent fevers. The *dose* of the recently-dried bark in powder is stated to be from 20 to 60 grains (Gm. 2-4), frequently repeated. The infusion or decoction is less eligible than the tincture, which is not, however, official.

MALTUM, U. S.—MALT.

Maltum hordei.—Barley malt, E.; *Malt d'orge*, *Drêche*, Fr.; *Malz*, *Gerstenmalz*, G.

The seed of *Hordeum distichum*, *Linne* (Nat. Ord. Graminaeae), caused to enter the incipient stage of germination by artificial means, and dried.

Preparation and Properties.—Different kinds of grain may be employed for the preparation of malt, but the kind most generally used is barley. The grain is soaked in water, and then placed in heaps; heat is spontaneously generated, and by occasional turning prevented from rising too high. Under these conditions germination takes place, and when the germ has acquired the desired length the grain is rapidly dried, and constitutes *malt*. According to the degree of heat employed in drying the color of the malt varies somewhat, and is known as either *pale*, *pale amber*, *amber*, or *amber-brown*. For

some purposes malt is made to undergo a roasting process in revolving cylinders, to obtain *roasted* or *black* malt if the integuments are of a dark-brown color, or *crystallized* malt if the interior of the grain has become dark-brown. Malt has an agreeable odor and a sweet taste, and yields with water a more or less deep yellowish-brown or brown infusion. Only pale or pale amber-colored malt is employed medicinally.

Constituents.—The chemical changes taking place in germinating grain and sprouting potatoes were explained by Payen and Persoz (1833), who discovered a peculiar ferment, *diastase*, which exists in the vicinity of the embryo, but not in the radicle of the germ; on making an infusion of fresh malt, precipitating salts and some proteids with a little alcohol, and then adding more alcohol, diastase in an approximately pure condition is precipitated, but, according to Dubrunfaut (1868), is a mixture which contains the true fermentative principle, *maltin*. The remaining constituents of malt are those of barley, with the exception of *dextrin* (see pp. 199 and 768) and *sugar*, which have been formed from a portion of the starch, the remainder of which, still present in the malt, is likewise converted into the same compounds by the process of *mashing*, which consists in preparing an infusion of ground malt, called *wort*, and keeping it at a temperature of about 70° C. (158° F.).

During the process of malting good barley increases about 9 per cent. in volume, but loses about 20 per cent. in weight, and good malt should yield to water soluble principles amounting to two-thirds of its weight. Diastase has the property of converting starch into dextrin and sugar, and in this respect resembles *ptyalin*, a ferment met with in the salivary glands of animals. Coutaret (1870) regards the two ferments as being identical.

Off. Prep.—Extractum malti, U. S.

Medical Action and Uses.—Liquid and semi-fluid extracts of malt were much used a few years ago in Germany, where they were first introduced, as tonic and nutritious substitutes for malt liquors. Thence they were diffused to every part of the world, until their local manufacture displaced the imported preparations, and both were superseded by some later fashionable medicine. In many cases they were found quite beneficial in states of chronic debility and *dyspepsia* due to organic disease or infirmity or to mere nervous exhaustion, but seldom more, and often less so, than good malt liquors into the composition of which hops enter. Malt appears to be especially adapted to promote the digestion of amylaceous food by promoting its conversion into dextrin and glucose. The semi-liquid preparation, which is the only true extract of malt, is very difficult to take, owing to its tenacious and adhesive qualities, and is generally prescribed in teaspoonful doses mixed with soup, wine, beer, or milk. It should be taken at the beginning of a meal or while it is being eaten. Malt preparations are of use in tubercular *phthisis* and other wasting diseases only because they enable the digestive organs to assimilate more food than it would otherwise be possible to digest.

An infusion of malt made with cold water is an energetic diastatic agent. The following directions may be followed in its preparation: “3 ounces (or piled-up tablespoonfuls) of crushed malt are thoroughly well mixed in a suitable vessel with $\frac{1}{2}$ pint of cold water. The mixture is allowed to stand over night—that is to say, for 12 or 15 hours. It is then filtered through until it becomes perfectly bright. The above quantities yield about 7 ounces of product of a sherry-brown color and a faint sweetish taste. It is nearly neutral, and its sp. gr. about 1025. Its chief solid constituent is maltose, and is rich in diastase. . . . It is very prone to fermentation, and ought to be prepared fresh every day” (Roberts, *Practitioner*, xxiii. 405). A tablespoonful of this liquid, added to $\frac{1}{2}$ pint of gruel prepared from wheat or other flour, or from oatmeal, groats, pearl-barley, arrow-root, or another farina, and at a temperature not too high for being eaten, will immediately transform the starchy ingredients of the mixture into sugar and dextrin. In this manner a food may be formed which will save or prolong the life of patients affected with tubercle, marasmus, or any *wasting disease* in which all other forms of nutriment are either vomited or passed by stool. Above all, it is valuable in the treatment of two of the most fatal diseases of infancy, *cholera infantum* and *summer diarrhoea*.

It appears that in Japan malt (*midzu ame*) has long been used for similar purposes (Eldridge, *Med. News*, xlv. 114).

MANGANI OXIDUM NIGRUM, U. S.—BLACK OXIDE OF MANGANESE.

Manganesi oxidum nigrum, Br., U. S. 1870; *Manganum hyperoxydatum*, *Oxydum manganicum*, *Magnesia vitriariorum*.—Dioxide (Peroxyde) of manganese, *Pyrolusite*, E.; *Oxyde (Peroxyde) de manganèse*, Fr.; *Braunstein*, *Mangansuperoxyd*, G.

Native, crude binoxide of manganese, containing at least 66 per cent. of the pure oxide. (Formula MnO_2 . Molecular weight 86.)

Origin.—Pyrolusite—or, as it is commercially called, *black manganese* or *manganese*—is found in different parts of Germany, France, Spain, and Great Britain, and also in Nova Scotia, Vermont, Pennsylvania, and other parts of North America. Sometimes it is found nearly pure, but it is generally associated with other manganic ores, particularly with the inferior brown *manganite*, and often with iron, lime, baryta, silica, etc. It may also be obtained artificially by carefully fusing manganous carbonate with potassium chlorate and washing the mass, or, according to Walter Weldon (1867), by exposing a mixture of manganous hydroxide and lime to the air at a temperature of about 55°C . (131°F). The average importation of ore and oxide of manganese into the United States for the eight years ending 1880 was nearly 1,700,000 pounds annually.

Properties.—It is amorphous, and is then of a dull gray-black color, or in masses composed of tabular, fibrous, or radiating crystals having a bright metallic lustre and yielding a black or grayish-black, somewhat gritty, tasteless powder. Its specific gravity is 4.7 to 4.94. It is insoluble in water and in all simple solvents, as well as in weak acids; it dissolves in hot hydrochloric acid to manganous chloride, while chlorine is given off; $\text{MnO}_2 + 4\text{HCl}$ yields $\text{MnCl}_2 + 2\text{H}_2\text{O} + \text{Cl}_2$. When it is treated with diluted sulphuric acid in the presence of oxalic acid, the latter is oxidized to carbonic acid, manganous sulphate being dissolved; $\text{MnO}_2 + \text{H}_2\text{SO}_4 + \text{H}_2\text{C}_2\text{O}_4$ yields $2\text{CO}_2 + \text{MnSO}_4 + 2\text{H}_2\text{O}$. When heated to redness the black oxide parts with a portion of its oxygen, leaving brown manganic oxide, Mn_2O_3 , or at a bright-red heat red manganoso-manganic oxide, $\text{MnO} \cdot \text{Mn}_2\text{O}_3$; and when mixed with potassa and potassium chlorate and heated to dull redness, a black-green mass of potassium manganate is obtained, which yields with cold water a deep-green solution, the color changing to purple on the addition of an acid or on boiling, potassium permanganate being produced.

Valuation.—The value of black oxide of manganese for the production of chlorine may be determined in various ways, either by ascertaining directly the loss in weight occasioned by the evolution of carbonic acid gas in the reaction just described, when the weight of 2CO_2 (88) will indicate 1 molecule of MnO_2 (86), or after the reaction has been completed the excess of the oxalic acid added is estimated by a standardized solution of potassium permanganate, which is added until it ceases to be decolorized. The generation of chlorine and its oxidizing effect upon ferrous salts are utilized for the same purpose in the following manner: 5 Gm. (or 50 grains) of the finely-powdered oxide are mixed in a flask with about 15 Gm. of water and 35 Gm. (or 1 ounce) of strong hydrochloric acid; 32.3 Gm. (or 323 grains) of pure granular ferrous sulphate are likewise weighed out and added, at first in larger, afterward in smaller, portions, until, after some digestion, the odor of chlorine has entirely disappeared and a drop of the liquid is colored blue by ferricyanide of potassium from the excess of ferrous salt. If the oxide was pure MnO_2 (accepting the molecular weight 86), it would require 32.3 Gm. (or 323 grains) of the ferrous sulphate; from the exact quantity of the latter used the percentage of the former is easily calculated. The Pharmacopœia requires black manganese to contain at least 66 per cent. of MnO_2 , and if of this strength the above quantity, after the addition of 21.3 Gm. (or 213 grains), will give no blue reaction with the ferricyanide. This is the process of assay adopted by the Pharmacopœia, the quantities directed being black oxide of manganese 5 Gm., water 15 Gm., hydrochloric acid 20 Gm., and ferrous sulphate 21 Gm., which indicate only 65 (not 66) per cent. of pure manganese dioxide. The 32.3 Gm. (or 323 grains) of the ferrous sulphate may also be added at once, and after the completion of the reaction its excess ascertained by standardized permanganate of potassium.

Impurities.—The presence of carbonates is detected by the effervescence occurring with cold dilute hydrochloric acid, and the presence of iron is ascertained in the solution obtained with strong or with hot dilute hydrochloric acid by the blue precipitate with ferrocyanide of potassium.

Composition.—Black oxide of manganese consists of 62.8 parts (1 atom) of manganum and 37.2 parts (2 atoms) of oxygen.

The metal *manganum*, *manganium*, or *manganesium* was first isolated by Gahn (1774), after Pott, Scheele, Bergmann, and others had shown black manganese to be free from iron: it may be obtained by reducing one of its oxides with carbon at a very high temperature. It resembles iron, but is harder, more brittle, and has a lighter or darker, sometimes a reddish, tint; its specific gravity is 7.13–7.21 (Brunner), and it melts at a white heat. Besides the oxygen compounds mentioned above it unites with this element also in several other proportions. *Manganous oxide*, MnO , is a grayish-green powder which

readily oxidizes in contact with the air. *Manganic acid*, H_2MnO_4 , is not known in the free state, but only in the form of salts, which have a green color. *Manganic heptoxide*, Mn_2O_7 , is a heavy, dark red-brown, oily liquid which detonates violently when heated to between 30° and 40° C. (86° and 104° C.). *Permanganic acid*, $\text{H}_2\text{Mn}_2\text{O}_8$, is a deep violet-colored liquid which is a powerful oxidizing agent. (See POTASSIUM PERMANGANATE.)

Uses.—Black oxide of manganese is used for the preparation of oxygen and largely in the manufacture of chlorine, and the solution obtained in this process may be employed for preparing other compounds of manganese. It is employed in preparing Aqua (liquor) chlori. *U. S.*, *Br.*; Hydrarg. perchloridum, *Liq. sodæ chloratæ*, *Potass. chloras*, *Potass. permanganas*, *Br.*

Medical Action and Uses.—Black oxide of manganese was introduced into medicine when its chemical affinities were found to be nearly analogous to those of iron. But the chemical ground of judgment proved, as it usually does in therapeutics, a fallacious one, and none of the curative effects anticipated were secured. On a different ground, probably, it was employed in the treatment of morbid sensibility of the stomach—an affection which was doubtless, in some cases, *gastralgia*, and in others *simple ulcer*. When it was of service in such cases it probably acted as bismuth subcarbonate or subnitrate acts, by furnishing an inert and insoluble coating to the part. It was given in the dose of from 5 to 40 grains (*Gm.* 0.30–3).

MANGANI SULPHAS, *U. S.*—SULPHATE OF MANGANESE.

Manganesi sulphas, *U. S.* 1870; *Manganum sulfuricum*, *P. G.*; *Sulfus manganosus*.—*Manganous sulphate*, *E.*; *Sulfate de manganèse*, *Sulfate manganoux*, *Fr.*; *Manganosulfat*, *Schwefelsaures Manganoxydul*, *G.*

Formula $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$. Molecular weight 222.

Description.—Black oxide of manganese is mixed with sufficient strong sulphuric acid to obtain a thin magma, which is heated to boiling and evaporated to dryness; the mass is now heated in a crucible to dull redness for some time for the purpose of decomposing the iron sulphate. When cool it is treated with water, and the solution, if iron be still present, digested with manganous carbonate, then filtered, and evaporated to crystallize.

Properties.—When crystallized below 6° C. (43° F.) the salt contains $7\text{H}_2\text{O}$, and is isomorphous with ferrous sulphate; above that temperature and below 20° C. (68° F.) it contains only $5\text{H}_2\text{O}$ and has the form of copper sulphate. But the salt usually met with is crystallized between 20° and 30° C. (86° F.), and forms right rhombic—or, according to Marignac, monoclinic—prisms, containing $4\text{H}_2\text{O}$, three of which are given off at a temperature of 115° C. (239° F.). A salt of the same composition as this residue is also obtained by adding sulphuric acid to solution of manganous sulphate and evaporating; it forms a granular powder. The crystals of the official salt are transparent and colorless, or more frequently of a pale rose-red color, slightly efflorescent in a dry atmosphere, insoluble in strong alcohol, but dissolve at 15° C. (59° F.) in 150 parts of 60 per cent., in 50 parts of 50 per cent., and in 2 parts of 10 per cent., alcohol. The salt requires at 15° C. (59° F.) 0.8 (Brandes), 1.06 parts (Mulder) of water, and 1.08 (Brandes), 1.28 (Mulder) parts of boiling water; at 55° C. (131° F.) 0.9 part of water is required. The solution has a styptic and slightly bitter taste, a neutral or faintly acid reaction, and yields with ammonium sulphide a flesh-colored precipitate, with ferrocyanide a white one, and with ferricyanide a grayish-brown one, but is not disturbed by tannic acid. The fixed alkalies and alkaline carbonates produce white precipitates, which on exposure to air are rapidly oxidized, turning brown. Barium chloride yields an insoluble white precipitate.

Tests.—The most common impurity likely to be met with is sulphate of iron, the presence of which would be indicated by the blue-black color produced with solution of tannin or by the more or less deep-blue color of the precipitate with potassium ferrocyanide. Sulphate of copper would in the slightly acidulated solution produce a black precipitate with sulphuretted hydrogen. The precipitate with ammonium sulphide should be completely soluble in acetic acid, proving the absence of zinc salt. The sulphates of magnesium and the fixed alkalies are indicated by the residue left after precipitating the solution completely with ammonium sulphhydrate or carbonate, evaporating the filtrate to dryness, and igniting; the Pharmacopœia permits a trace of these last impurities. When heated to dull redness the salt should lose 32.4 per cent. of its weight (water of crystallization).

Other Compounds.—**MANGANI CARBONAS.** Carbonate of manganum is prepared by precipitating in the presence of a little syrup a solution of manganous sulphate with carbonate of sodium, washing the precipitate well, and drying it rapidly with a moderate heat. It is a white powder having a brownish tinge and dissolving in carbonic acid water, leaving only a slight residue of brown manganic oxide.

MANGANI CHLORIDUM. Chloride of manganum is most economically obtained when preparing chlorine from black oxide of manganese and hydrochloric acid; the resulting liquid is digested with manganous carbonate until the iron has been completely precipitated; the filtrate is evaporated, crystallized, and by recrystallization purified from calcium chloride if present. The salt is in granular, or when slowly evaporated in tabular, crystals of a pale rose-red color, and has the composition $MnCl_2 \cdot 4H_2O$ (mol. weight 196.8). It is soluble in alcohol, and requires at ordinary temperature about $2\frac{1}{2}$ parts of water for solution.

MANGANI IODIDUM. Manganous iodide is a very deliquescent salt, and is best administered in the form of *syrup*, which may be prepared by dissolving manganous carbonate in hydriodic acid, or by the following formula proposed by Prof. Procter (1850): Take of sulphate of manganese 16 drachms; iodide of potassium 19 drachms; sugar, water, each sufficient. Dissolve each of the salts in 3 fluidounces of water containing 2 drachms of syrup; mix, and after precipitation filter the solution into a bottle containing 12 ounces of sugar; add water to make a pint, and shake the bottle till the sugar is dissolved. Each fluidounce contains 1 drachm of iodide of manganum; it may be given in doses of 10 drops to $\frac{1}{2}$ fluidrachm.

The same author has also proposed a *syrup of the iodides of iron and manganese*, to be prepared as follows: Take of iodide of potassium 1000 grains; ferrous sulphate 630 grains; sulphate of manganese 210 grains; clean iron filings 100 grains; powdered sugar 4800 grains; distilled water sufficient. Rub the sulphates and iodide separately to powder, mix with the iron filings, add $\frac{1}{4}$ fluidounce of water, and rub to a uniform paste; add the same quantity of water a second and a third time at intervals of 15 minutes, and rub. Place the sugar in a bottle, and drain the dense solution into it through a filter, adding water slowly to the magma, until the solution of the iodides is displaced and the water measures 12 fluidounces. Lastly, agitate the bottle till the sugar is dissolved. Each fluidounce contains 50 grains of the iodides in the proportion of 3 parts of iodide of iron to 1 of iodide of manganum. The dose is the same as the preceding. Both syrups contain some potassium sulphate.

MANGANI LACTAS. Lactate of manganum is formed by adding manganous carbonate to hot lactic acid; on evaporating the filtrate the salt is obtained in pale rose-red shining crystals, which contain 19 per cent. of water of crystallization, are soluble in 12 parts of cold water, and dissolve likewise in hot alcohol, crystallizing again on cooling.

MANGANI PHOSPHAS. Manganous phosphate is obtained by precipitating 10 parts of manganous sulphate with 11 parts or sufficient of phosphate of sodium, each separately dissolved in about 80 parts of water, washing the precipitate well to remove the sodium sulphate, and drying. It is a white crystalline powder, sometimes with a reddish tint, having the composition $Mn_3P_2O_8 \cdot 4H_2O$ (mol. weight 424) and dissolving readily in dilute acids. A syrup has been recommended by T. S. Wiegand (1834); the salt may be dissolved in dilute hydrochloric, or, better still, in phosphoric acid, and sufficient sugar dissolved in the cold solution.

MANGANI TANNAS. Tannate of manganum was recommended by Marletta (1865). It is obtained by adding recently-precipitated manganous carbonate to a hot solution of tannic acid in distilled water until it ceases to dissolve, filtering, and evaporating to dryness. The carbonate must be absolutely free from iron, and the solution must be protected from contact with iron, otherwise it will acquire an inky color. The salt is soluble in water, and when prescribed in solution syrup or glycerin should be added for preservation.

MANGANI TARTRAS. Tartrate of manganum. On dissolving 10 parts of Rochelle salt and 8 parts of manganous sulphate, each in its own weight of hot water, and mixing the solutions, small white or pale-reddish crystals of manganous tartrate are obtained on cooling which must be washed with cold water, since hot water decomposes them into a soluble acid and an insoluble basic salt.

Physiological Action.—Sulphate of manganese is as energetic as the black oxide is inert. In experiments upon animals, when given internally in large doses, it occasions vomiting and gastro-intestinal inflammation; injected into the veins, it causes vomiting and purging, dyspnoea, rapid exhaustion, paralysis, and death, and after this traces of gastro-intestinal inflammation, and even ulceration, with congestion of the liver and spleen, while liquid or coagulated blood is found on both sides of the heart. In some experiments it occasioned a profuse secretion of bile, and in others it was found to diminish the blood-pressure and paralyze the muscles of animal life. It is generally stated that sulphate of manganese possesses the qualities of caustic potassa or soda, dissolving the tissues, and in no wise the astringent action of iron salts.

More than half a century ago Gmelin performed the experiments with sulphate of manganese which are summarized in the preceding paragraph.

More recent experiments have shown that the salts formed by manganese with organic acids weaken the heart's action, prolong its diastole, diminish the arterial blood-pressure, tend to paralyze the muscular system, and increase the excretion of nitrogenous com-

pounds. (Compare Robert, *Practitioner*, xxxi. 454.) Apparently ignorant of these experiments or of their bearing, a non-medical scientist on the one hand, and on the other a pharmacist and a surgeon, drew the conclusion that because manganese had been detected in the blood, and because in its chemical habitudes it closely resembles iron, therefore it must possess therapeutical virtues analogous to those of iron, and might be used at least to reinforce the latter metal. The folly of some of these theorists went even so far as to suggest the idea that, inasmuch as in nearly all martial preparations there is some manganese, they may possibly derive their virtues from it and not from the iron they contain. The above statement of the physiological action of manganese exhibits the absolute antagonism of its action to that of iron in every point.

Medical Uses.—Sulphate of manganese has been employed as a *cholagogue* purgative in *jaundice* and other affections associated with hepatic engorgement, but its irritating qualities render it an unsafe remedy. The dose of sulphate of manganese is from 2 to 5 grains (Gm. 0.10–0.30). Its advantages as a substitute for iron are quite illusory. An ointment made with this salt which acts as an irritant upon the skin has been applied by friction to *glandular indurations* and swellings of the *joints*. The chloride has occasionally been used to stimulate indolent *ulcers*, especially those of a syphilitic origin, but it possesses no superiority over the usual topical applications made for this purpose. Of the other manganic compounds above described it need only be said that they possess no recognized therapeutical value. (A further consideration of manganic compounds will be found under PERMANGANATE OF POTASSIUM.)

MANNA, U. S., Br., P. G.—MANNA.

Manne, Fr.; *Manna*, G.

The concrete saccharine exudation, in flakes, of *Fraxinus Ornus*. *Linné*, s. *Ornus europæa*, *Persoon*. Steph. and Church, *Med. Bot.*, plate 53; Bentley and Trimen, *Med. Plants*, 170. *Nat. Ord.*—Oleaceæ.

Origin.—The manna ash, or flowering ash, is a slender tree about 12 to 20 feet (3.6–6 M.) high, with opposite pinnate leaves and small white diandrous flowers grouped together on a terminal, drooping, very elegant panicle. It is indigenous to the countries bordering the Mediterranean on the north from Asia Minor west to Spain, and has been introduced into Central Europe and England as an ornamental tree. The foliage, even on the same tree, is frequently very variable, and *Fraxinus rotundifolia*, *Lamarck*, cannot be regarded as a distinct species nor even as a well-marked variety.

Collection.—Manna is at present collected for commercial purposes solely in Sicily, as was ascertained by Hanbury, the plantations or *frassinetti* being chiefly on the northern shore of that island. When the tree is about eight years old and its trunk at least 3 inches (75 Mm.) in diameter, it will yield manna and remain productive for from 12 to 20 years, when the stem is cut down and replaced by a shoot from the stump. The incisions are made in dry weather with a hooked knife, one each day, commencing near the root and directly above each other; they are transverse, 2 inches (5 Cm.) or less in length, and penetrate through the bark to the wood. In the following year the same operation is repeated on the untouched side, and this is continued from year to year until the tree ceases to be productive. The juice flowing from the lower incisions is collected on tiles or in receptacles made from the stem of an *Opuntia*; that from the upper incisions hardens on the stem, or, for producing a superior variety called *manna a cannolo* which is rarely seen in commerce, is allowed to harden on sticks or straws inserted into the cuts. When sufficiently hard the large pieces are gathered, and completely dried before being packed, while the smaller ones are afterward scraped from the stem and sold separately. The annual exportation averages about 3000 cwt., about one-tenth of which is sent to the United States.

Description.—The varieties of manna generally distinguished in our commerce are *large flake*, *small flake*, and *sorts*. Flake manna (*Manna cannulata*, P. G.) consists of three-edged pieces varying in length from $\frac{1}{2}$ inch to 6 or 8 inches (1 to 15 or 20 Cm.), $\frac{1}{2}$ to 1 or 2 inches (1 to 5 Cm.) wide, and somewhat less in thickness, flat or curved on one side where it adhered to the tree, and uneven from roundish projections on the others, showing the marks of different layers. It is externally of a yellowish-white, in some places pale-brownish, color, friable, internally porous, and the cavities filled with white glistening crystals of mannit. Its odor is saccharine, somewhat nauseous, and its taste sweet and honey-like, but combined with a very slight bitterness and acidity. Large and small flake manna differ only in size, the latter, however, being often of a darker

shade. Manna in sorts (*Manna communis*, P. G., s. *geracina*) consists of the scrapings, and is met with in fragments of the size of a pin's head to about $\frac{1}{2}$ inch (12 Mm.) in diameter, with a rather adhesive surface and of a brownish color outside, but internally nearly white and crystalline; not unfrequently the fragments are united by a viscid brownish matter, which, without the flakes, constitutes *fat manna* (*Manna pinguis*, s. *crassa*, s. *de Puglia*) a variety rarely seen in this country, and rejected by the pharmacopœias. It flows from the incisions late in autumn, and is more particularly yielded by old trees; it is soft and glutinous, entirely devoid of crystals, and less agreeable in odor and taste than flake manna, from which it differs in containing much less mannit and more gum, sugar, and coloring matter. The U. S. P. gives 0.834 as the specific gravity of manna, which is an error, manna being heavier than water; it probably intended to state that manna should dissolve in 15 parts of alcohol of the spec. grav. .834.

Manna dissolves in about 6 parts of cold water, yielding a nearly clear solution, and is less soluble in alcohol, leaving little residue.

Sophistication.—Manna has occasionally been sophisticated by mixtures made of bread-crumbs, starch, glucose, etc., which are very readily discovered if practised with flake manna; starchy substances can also be readily detected in manna sorts by the iodine tests.

Tests.—On boiling 5 parts of manna with 100 parts of alcohol a solution should be obtained which does not affect the color of litmus, and while cooling deposits many crystals of mannit; the undissolved residue, about 1 per cent., should be solid, not viscid. Manna dried in the water-bath should lose not over 10 per cent. of moisture.—P. G.

Constituents.—The best dry flake manna contains about 90 per cent. of mannit, the remainder being fermentable sugar, resin, and mucilage. Mannit, $C_6H_8(OH)_6 = C_6H_{14}O_6$, was discovered by Proust (1806), and may be obtained by treating manna with boiling alcohol and recrystallizing several times from hot alcohol. Charles T. Bonsall (1853) recommends the dissolving of manna in three times its weight of boiling water, precipitating gum and coloring matter by a little subacetate of lead, removing excess of lead by sulphuretted hydrogen or a little sulphuric acid, concentrating the filtrate and pouring the hot syrupy liquid into twice its bulk of cold alcohol; the mannit will crystallize on cooling. It crystallizes in colorless needles or glossy rhombic prisms which fuse at $165^\circ C.$ ($329^\circ F.$) and boil near $200^\circ C.$ ($392^\circ F.$), when a portion sublimes unaltered, but most of it is converted into mannitan, $C_6H_{12}O_5$, a sweetish, syrupy liquid. Mannit dissolves in about 6 parts of cold and in much less hot water, in 90 parts of cold 67 per cent. alcohol, and is insoluble in ether and nearly so in absolute alcohol. The solutions scarcely affect polarized light, are not altered by boiling with dilute acids, and do not reduce Fehling's solution. It unites with bases, forming compounds which are insoluble in alcohol. Nitric acid converts it into racemic acid and sugar, and ultimately into saccharic and oxalic acids. Gorup-Besanez (1861) observed that moist platinum-black converts it into mannitic acid, $C_6H_{12}O_7$, and mannitose, $C_6H_{12}O_6$, which is fermentable, but optically inactive. Berthelot (1856) has shown that under certain circumstances mannit will undergo alcoholic fermentation. Mannit has been found in a large number of plants, is formed in small quantity during the alcoholic fermentation of sugar, and may be obtained artificially by acting upon glucose with sodium amalgam.

The fermentable sugar present in manna reduces Fehling's solution very readily, and the mucilaginous matter is partly precipitated by acetate of lead, partly by subacetate. The resin is soluble in ether, and has a brown-red color and an acid taste. The green color observed in some pieces of manna is due to *fraxin*, $C_{32}H_{38}O_{20}$, which was discovered by Salm-Horstmar (1857) in the bark of *Fraxinus excelsior*, the European ash (see pp. 713 and 765), and splits with dilute acids into glucose and *fraxetin*, $C_{10}H_{10}O_5$.

Pharmaceutical Preparation.—**SYRUPUS MANNÆ.** Syrup of manna. Dissolve 10 parts of manna in 40 parts of distilled water, filter, and add 50 parts of sugar.—P. G.

Other Mannas.—The sweet exudations of various trees have received the name of manna: that sometimes obtained in Southern Europe from incisions into the trunk of *Fraxinus excelsior*, *Linne*, is identical with the foregoing. The young shoots of the European larch, *Pinus Larix*, *Linne*, yield in the middle of summer a white exudation known as *Briançon manna* and containing the sugar *mellezitose*, $C_{12}H_{22}O_{11} \cdot 3H_2O$. The leaves of *Eucalyptus viminalis*, *Labillardiere*, and other species of Australia, yield *Australian manna*, containing *melitose*, $C_{12}H_{22}O_{14}$. *Persian manna* comes from *Alhagi Camelorum*, *Fischer* (Leguminosæ), and contains spines and leaflets of the plant; other varieties are produced by *Salix fragilis*, *Linne*, and different species of *Astragalus*. *Tamarisk manna* exudes from *Tamarix mannifera*, *Ehrenberg*, in consequence of the puncture made by an insect, *Coccus manniparus*, *Ehrenberg*, and is collected near Mount Sinai, and sold by the monks of the convent of St. Catharine; it contains cane-sugar, glucose, and dextrin.

Armenian (oak) manna results from the puncture of a Coccus upon the leaves of *Quercus Valonea*, *Kotschy*, and *Q. persica*, *Jaubert et Spach*: it is either dissolved from the leaves by water, which is evaporated, or else scraped off, and then is mixed with numerous small fragments of the leaves; it consists chiefly of grape-sugar. *Lebanon manna* is in small sweet grains obtained from *Cedrus libanotica*, *Link.* Saccharine exudations have been observed upon a number of other plants, and the saccharine products of some insects, like the *trehala (tigala)* of Syria, containing the peculiar sugar *trehalose*, and the *terp* of Australia, have sometimes been classed with the mannas; they are not entirely soluble in water.

Medical Uses.—Manna is a *laxative* peculiarly adapted to children and pregnant women; it is also a gentle *cholagogue*, and at the same time a suitable *expectorant* in febrile affections of the lungs. Some writers have held it to be peculiarly fitted, owing to the mildness of its action, to be employed in cases of *piles* and of *genito-urinary irritation*. It is slow in its operation, and is not apt to leave the bowels confined, but it tends to occasion flatulence and colic. It may be given in doses of from half an ounce to an ounce (Gm. 16–32), dissolved in hot water. Formerly, as at the present day, it was often associated with rhubarb, tamarinds, or senna, and it forms one of the ingredients of *the black draught*: $\mathcal{R}$. Sennæ $\mathfrak{zss}$; Magnesiae sulph. Mannaē $\mathfrak{aa}$ $\mathfrak{zss}$; Sem. fœniculi $\mathfrak{zj}$; Aquæ bull. Oss.—*M.* Macerate in a covered vessel until the liquid cools. One-third of it may be given every four or five hours until it operates. The same infusion may be made with cold water by percolation. It is less nauseous and has a slighter tendency to gripe.

MARMOR ALBUM, *Br.*—WHITE MARBLE.

Marmor, U. S. 1870.—*Marble*, E; *Marbre*, Fr.; *Marmor*, G.

Formula CaCO_3 . Molecular weight 100.

Native white granular carbonate of calcium.

Properties.—Marble is found in various parts of the globe, the white kind being nearly pure carbonate of calcium, while the colored varieties are more or less tinged or variegated by the presence of oxides of iron and magnanum or by bituminous matter. It is met with in masses which are an aggregation of minute crystals, imparting a granular and glistening appearance. It has the specific gravity 2.7, is brittle, hard, insoluble in the ordinary solvents, but entirely soluble in dilute hydrochloric acid, carbonic acid gas being given off. It is used in pharmacy for generating the gas mentioned, for which purpose black marble containing bituminous compounds is inadmissible, but other varieties may be used. In case the solution in hydrochloric acid is to be used for the preparation of other calcium compounds, it must be completely freed from iron by digesting it with milk of lime, and after filtration should not be precipitated by a solution of sulphate of calcium (absence of barium and strontium), nor by ammonium phosphate after the previous addition of excess of ammonium chloride and ammonium carbonate and filtration (absence of magnesium).

Marble has the same composition as chalk, and when heated to redness parts with carbonic acid gas, leaving lime or oxide of calcium, CaO .

Pharmaceutical Uses.—In producing carbonic acid gas and for preparing *Liquor calcii chloridi*.

MARRUBIUM, U. S.—HOREHOUND.

Herba marrubii.—*Hoarhound*, E.; *Herbe de marrube blanc*, Fr.; *Andornkraut*, *Weisser Andorn*, G.

The leaves and tops of *Marrubium vulgare*, *Linneé*. Bentley and Trimen, *Med. Plants*, 210.

Nat. Ord.—*Labiatae*, *Stachydeæ*.

Origin.—Horehound is a perennial herb, and is found in waste places in Asia from Northern India westward to the Mediterranean, and throughout Europe except the extreme north; it has been naturalized in Canada and in many parts of the United States westward to California, also in some parts of South America. It is not unfrequently met with in gardens, and it flowers from June to September.

Description.—The branching stem is about a foot (30 Cm.) high, quadrangular, much-branched, and covered with a white felt. The leaves are opposite, petiolate, about an inch (25 Mm.) long, roundish-ovate, somewhat heart-shaped or rounded at the base, obtuse, serrate or coarsely crenate, wrinkled by the prominent veins below, pale-green and

downy above and white-hairy beneath. The flowers are in dense axillary whorls, with woolly, linear, and hooked bracts, a tubular ten-ribbed calyx divided into ten short, spreading, stiff, and hooked teeth, and a white bilabiate corolla enclosing four stamens. The four akenes are dark-brown.

Horehound has a strong, peculiar, and aromatic odor and an aromatic and persistent bitter taste.

Constituents.—Horehound contains, besides some resin, tannin, and other common principles, a small quantity of volatile oil, and *marrubiin*, a bitter principle discovered by Mein (1855). Harms obtained 30 grains from 25 pounds of the dry herb by treating the aqueous extract with alcohol, distilling the latter, and agitating the residue with ether, which dissolves the marrubiin. Kromer (1861) agitated the infusion with charcoal and exhausted the latter with hot alcohol, which dissolves the bitter principle and tannin; the latter is removed by oxide of lead. Marrubiin is slightly soluble in cold water, crystallizes from alcohol in prismatic and from ether in tabular crystals, is not precipitated by tannin, and has a very bitter and somewhat acrid taste.

Medical Uses.—Anciently regarded as a general stimulant, expectorant, deobstruent, carminative, and local anodyne, horehound continues to be employed as a stomachic tonic in *dyspepsia*, and in *chronic bronchitis* to restrain secretion. It has also been used in chronic rheumatism, hepatic and uterine disorders, and, like other bitter herbs, in intermittent fever. It has some reputation as an *anthelmintic*, and is said to diminish salivation. The *dose* of the powder is stated to be from 30 to 60 grains (Gm. 2–4). An infusion made with an ounce of horehound in a pint (Gm. 32 to Gm. 500) of hot water may be given in doses of a wine-glassful. The expressed juice should be administered with honey or milk in the dose of a teaspoonful or two (Gm. 4) several times a day. An extract is prepared in Europe.

MASSÆ PILULARUM.—PILL MASSES.

Masses pilulaires, Fr.; *Pillenmassen*, G.

The U. S. Pharmacopœia of 1880, in accordance with general custom, orders three pill masses to be kept in bulk, instead of one (*Pilula ferri carbonatis*) as heretofore, and designates such a pill mass as *Ma.ssa*, which is equivalent to *Pilula* adopted by the British Pharmacopœia. (For general remarks on the preparation of pill masses see *PILULÆ*.)

MASSA COPAIBÆ, U. S.—MASS OF COPAIBA.

Pilulæ copai bæ, U. S. 1870.—*Masse pilulaire de copahu*, Fr.; *Copaiva-Pillenmasse*, G.

Preparation.—Copaiba 94 parts (1 oz. av.); Magnesia, recently prepared, 6 parts (28½ grains); to make 100 parts (about 1 oz.). Mix them intimately, and set the mixture aside until it concretes into a pill mass.

Should the mixture not concrete in 8 or 10 hours a deficiency of water in the copaiba may be inferred; and this difficulty may be obviated in subsequent operations by shaking the copaiba with one-twentieth of its weight of water, allowing it to stand until all the uncombined water has subsided, and then decanting and keeping it in closed bottles for use.—U. S.

The proportion of copaiba has been slightly decreased, 94 parts being now directed instead of 96 parts for 6 parts of magnesia. The variety of copaiba best adapted for these pills is Maracaibo copaiba (p. 504), since it contains a larger proportion of resin; this enters into combination with the magnesia, forming a resin soap, which gradually becomes dry and hard. If thin Para copaiba is to be used for making these pills, it is advisable to evaporate sufficient of the volatile oil until the residue, after cooling, forms a viscid liquid, when it may be mixed with the magnesia. Recently-prepared magnesia is anhydrous, and does not easily combine with the copaivic acid until after it has become hydrated. In making the mixture it is, therefore, better to supply at once any deficiency in the water of hydration. The combination will also be hastened by the application to the mixture of a moderate heat for about 10 minutes. The *pilules de copahu* (F. Cod.) are made in the same manner, and contain 3.86 grains (0.25 Gm.) of copaiba; those of the U. S. P. 1870 contain 4.8 grains.

In Europe pills of copaiba and powdered cubebs are sometimes used, and made into a mass by means of wax. The quantities necessary are 1 part of each of the ingredients

named, or 3 parts of copaiba, 5 of cubebs, and 1 of wax. This mass retains its plasticity for a long time.

Medical Uses.—The efficiency of copaiba must necessarily be very much impaired by being given in so insoluble a combination. Each pill should contain about 5 grains of copaiba, and the average dose would be two or three pills.

MASSA FERRI CARBONATIS, U. S.—MASS OF CARBONATE OF IRON.

Pilula ferri carbonatis, U. S. 1870, Br.—*Vallet's mass*, *Vallet's pill mass*, E.; *Masse pilulaire de Vallet, de carbonate ferreux*, Fr.; *Vallet'sche Pillenmasse*, G.

Preparation.—Sulphate of Iron 100 parts (10 oz. av.); Carbonate of Sodium 110 parts (11 oz. av.); Clarified Honey 38 parts (3 oz. av. and 350 grains); Sugar, in coarse powder, 25 parts (2½ oz. av.); Syrup, Distilled Water, each a sufficient quantity; to make 100 parts (10 oz. av.). Dissolve the sulphate of iron and the carbonate of sodium separately, each in 200 parts (20 oz. av. or 19½ fluidounces) of boiling distilled water, and, having added 25 parts (2½ oz. av. or 15 fluidrachms) of syrup to the solution of the iron salt, filter both solutions. Mix them, when cold, in a bottle just large enough to hold them or add enough distilled water to fill it; close the bottle accurately with a stopper and set it aside, so that the carbonate of iron may subside. Pour off the supernatant liquid, and, having mixed syrup and distilled water in the proportion of 1 part (½ fluidounce) of syrup to 16 parts (10 fluidounces) of water, wash the precipitate with the mixture until the washings no longer have a saline taste. Drain the precipitate on a flannel cloth, and express as much of the water as possible. Lastly, mix the precipitate immediately with the honey and sugar, and by means of a water-bath evaporate the mixture, constantly stirring, until it is reduced to 100 parts (10 oz. av.).—U. S.

Take of saccharated carbonate of iron 1 ounce; confection of roses ¼ ounce. Beat them into a uniform mass.—Br.

The first process differs from that of the last Pharmacopœia only in the honey, of which now 38 parts (formerly 37½ parts) are ordered.

On mixing solutions of ferrous sulphate and sodium carbonate, ferrous carbonate and sodium sulphate are formed by mutual decomposition (see p. 689). In contact with air the white iron precipitate rapidly oxidizes. The change is prevented by washing the precipitate in bottles by decantation with water recently boiled, and excluding the air; an additional protection is afforded by dissolving some sugar in the water. The pill mass, when recently made, is of a greenish-gray color, but on exposure becomes superficially greenish-black. If properly made it contains nearly 42 per cent., and the mass of the Br. P. 34 per cent., of ferrous carbonate.

PILULÆ FERRI CARBONICI, P. G.; *Pil. ferratæ Valletii*.—Pills of ferrous carbonate, E.; *Pilules de Vallet*, *Pilules ferrugineuses*, Fr.; *Eisenpillen*, *Vallet'sche Pillen*, G.—Ferrous sulphate 100 parts is converted into carbonate with sodium bicarbonate by the process described on page 674; the washed precipitate is mixed with sugar 16 parts, honey 52 parts, and the mixture evaporated to 80 parts. 10 Gm. of this mass, with the requisite quantity of powdered marshmallow-root, are made into 100 pills, which are rolled in powdered cinnamon, and each of which represents .025 Gm. iron.—P. G.

The formula of the French Codex is almost identical with that of the United States Pharmacopœia, except that milk-sugar is used in place of sugar; 6 parts of the mass are mixed with 1 part each of powdered marshmallow- and liquorice-root, and divided into pills, each weighing 0.25 Gm., which are to be silvered.

Medical Uses.—Mass of carbonate of iron is one of the most efficient forms in which iron can be exhibited. It is especially indicated in pure *anæmia* and in *anæmic chlorosis*, and in all affections in which the red corpuscles of the blood are deficient, particularly when the digestive function is not greatly impaired. When dyspeptic disorders attend, the soluble preparations of iron are usually more efficient. The dose of mass of carbonate of iron is from 3 to 5 grains (Gm. 0.15–0.30), and should usually be taken at meal-time.

MASSA HYDRARGYRI, U. S.—MASS OF MERCURY.

Pilula hydrargyri, Br.; *Massa cœrulea*.—*Blue mass*, *Blue pill*, E.; *Masse pilulaire bleue*, Fr.; *Mercurial-Pillenmasse*, G.

Preparation.—Mercury 33 parts (3 oz. av.); Glycyrrhiza, in No. 60 powder, 5 parts (199 grains); Althæa, in No. 60 powder, 25 parts (2 oz. av. and 119 grains); Gly-

cerin 3 parts (120 grains); Honey of Rose 34 parts (3 oz. av. and 40 grains); to make 100 parts (9 oz. av. and 40 grains). Triturate the mercury with the honey of rose and glycerin until it is extinguished. Then gradually add the glycyrrhiza and althaea, and continue the trituration until globules of mercury cease to be visible under a lens magnifying 10 diameters.—*U. S.*

Mercury 2 parts; confection of roses 3 parts; liquorice-root, in fine powder, 1 part.—*Br., F. Cod.*

The British Pharmacopœia still directs the mercury to be extinguished by trituration with confection of roses, and the U. S. Pharmacopœia recommends trituration with a saccharine liquid (honey) containing a little glycerin, which facilitates the division of the metal. W. W. Stoddart (1855) has shown that the globules of mercury rapidly disappear on being triturated with powdered liquorice-root kept moist by a liquid; the directions above given may be conveniently modified in accordance with this suggestion, so that the mercury is first completely extinguished with the powdered glycyrrhiza and sufficient of the mixed liquids before the remaining powder and liquid are incorporated. The use of a considerable proportion of powdered althaea is an improvement, the mass being of a lighter color and of a purer blue tint; but the large amount of mucilage present in marshmallow-root favors the production of mould in a damp atmosphere; which tendency is in a measure counteracted by the glycerin.

When properly prepared, blue mass contains metallic mercury in the state of very fine division. It is not impossible that when kept on hand for a long time a change, due to the partial oxidation of mercury, may gradually take place, as has been repeatedly observed. Such a change, however, could only be very superficial, since the metal is well protected by the other ingredients of the pill mass.

PULVIS MASSÆ HYDRARGYRI, ÆTHIOPS SACCHARATUS.—Powdered blue mass, *E.*; Poudre de mercure saccharin. Mercure (Ethiops) saccharin, *Fr.*; Wurmzucker, *G.*

Blue mass or blue pill is not unfrequently ordered in powders, but is unsuited for the purpose unless mixed with other absorbent powders. It may, however, be readily obtained in the state of a permanent powder having the same relative composition as the pill mass by substituting in the above directions for the glycerin and honey of rose an equal weight of milk-sugar, using a drop of oil of roses to impart the requisite flavor, and keeping the mixture moist by the addition of alcohol; after a uniform mass has been obtained it is spread out to allow the alcohol to evaporate spontaneously, after which it may be reduced to a permanent powder. W. E. Bibby (1876) recommended 1 part of mercury to be triturated with 2 parts of sugar of milk, without adding any liquid, the metal being rapidly extinguished.

PILULÆ HYDRARGYRI; PILULÆ CÆRULEÆ, *F. Cod.*—Blue pills, *E.*; Pilules de mercure, Pilules bleues, *Fr.*; Mercurialpillen, *G.*—Each pill contains 0.05 Gm. ($\frac{3}{4}$ grain) of mercury, *F. Cod.* The pills of U. S. P. 1870 contained 1 grain of mercury.

Medical Action and Uses.—Mass of mercury, or blue mass, differs from other mercurials in irritating the stomach and the bowels less, and, therefore, in being less apt to act as a cathartic. For this reason, probably, it is more apt than they are to form combinations in the primæ viæ, which are readily absorbed and produce constitutional effects. Such effects are commonly sought from mercury in this form when it is given in *doses* of 3 grains (Gm. 0.20) or less, repeated several times a day until the characteristic soreness of the gums is observed. To prevent its acting as a laxative it is usually associated with $\frac{1}{4}$ grain (Gm. 0.01) or less of opium in each *dose*, or the mercurial is repeated at intervals of an hour or two in doses of $\frac{1}{4}$ or $\frac{1}{2}$ grain (Gm. 0.01–0.02). When it is desired to increase the secretions of the *liver* and *pancreas*, a dose of from 3 to 6 grains (Gm. 0.20–0.40) is usually administered at night, and is followed the next morning by a saline, or, still better, a senna, draught, or some other suitable cathartic. Whether the mercury does or does not specifically promote the secretion of the glands referred to is a question discussed elsewhere. (See HYDRARGYRUM.)

MASTICHE, *U. S., Br.*—MASTIC.

Mastix, Resina mastiche.—*Mastich, E.; Mastic, Fr.; Mastix, G.*

The concrete resinous exudation from *Pistacia Lentiscus*, *Linné*. Woodville, *Med. Bot.*, t. 11; Bentley and Trimen, *Med. Plants*, 68.

Nat. Ord.—Terebinthaceæ, Anacardiæ.

Origin.—A small tree or shrub which is indigenous to the basin of the Mediterranean.

has pinnate leaves with leathery sessile leaflets varying in form between linear and ovate, short-stalked, reddish-yellow pistillate, and larger greenish staminate, flowers, and small blackish drupes. Mastic is obtained in a few islands of the Grecian Archipelago, principally in Scio, from the var. γ Chia, which is tree-like and has broad leaves.

Collection.—The resin is contained in the bast-layer of the bark in elongated ducts having a large elliptic cavity and surrounded by one or more layers of small cells, in which the resin is secreted. To obtain it vertical incisions are made in June and July in the bark of the trunk and larger branches, and in July and August, after the exuding resin has hardened, it is carefully removed from the tree and collected in baskets; this is the finest quality. An inferior quality consists of the tears which have dropped from the incisions upon tiles or flat stones kept under the tree. A vigorous tree may yield 10 pounds of mastic; the total harvest is very variable, and occasionally reaches 50,000 cwt., but is generally considerably less. About 2000 pounds of mastic are annually consumed in the United States.

Description.—The best quality of mastic is in globular or more or less elongated brittle tears of the size of a pea, which are externally covered with a whitish dust or have been freed from it by washing, and are then of a pale-yellow color, perfectly transparent, of a glass-like lustre, and break readily with a conchoidal fracture. Placed between the teeth, it is easily crushed, and then softens into a plastic mass. Its specific gravity is about 1.07; it becomes soft below the boiling-point of water, but fuses at some degrees above it. It has a balsamic odor, more apparent on being heated, and a slight terebinthinous taste. It dissolves partly in alcohol, and is also soluble in benzol, acetone, volatile oils, cold creosote, and warm petroleum, leaving a whitish residue. The alcoholic solution reddens litmus.

The inferior kinds of mastic consist of similar tears, to which sand and fragments of bark adhere, mixed with gray- or brown-colored pieces.

Constituents.—Mastic contains a minute quantity of *volatile oil* and about 90 per cent. of *alpha-resin* or *masticic acid*, which is soluble in cold alcohol, combines with bases, and, according to Johnston, has the composition $C_{20}H_{32}O_2$. The portion insoluble in alcohol is white, tenacious, soluble in ether and oil of turpentine, and has been named *beta-resin* or *masticin*; its composition is $C_{20}H_{31}O_2$. Hot water dissolves the bitter principle, acquires an acid reaction, and the solution gives a precipitate with tannin.

Varieties and Adulterations.—**BOMBAY MASTIC.** Under this name a drug has appeared in the market which, when well selected and clean, closely resembles the Scio mastic, but is usually in less clean and more opaque tears. It is obtained from *Pistacia cabulica* and *Khinjuk*, *Stocks*, which are indigenous to North-western India and Beloochistan. *Pist. atlantica*, *Desfontaines*, a variety of *Pist. Terebinthus*, *Limé*, growing in Algeria and other parts of Northern Africa, yields likewise a mastic-like resin.

SANDARACA.—*Sandarac, E.*; *Sandaraque, Fr.*; *Sandarac, G.*—It is the exudation of *Callitris quadrivalvis*, *Ventenat*, s. *Thuja articulata*, *Vahl* (Nat. Ord. Coniferae, Cupressineae), a small tree of North-western Africa. It forms brittle elongated tears of a pale-yellowish color, with a dusty surface, the fracture glass-like and transparent, almost wholly soluble in alcohol, and becoming pulverulent when masticated.

The tears of *olibanum* are generally larger, translucent, and destitute of glassy lustre. The exudation of *Atractylis gummifera* is sold in Greece as *pseudo-mastic* or *acantho-mastic*, and consists of agglutinated tears which are oblong in shape and about 2 inches (5 Cm.) long by 1 inch (25 Mm.) in thickness.

Off. Prep.—*Pilulæ aloes et mastiches, U. S.*

Medical Uses.—Formerly employed internally for purposes similar to those for which other terebinthinates are prescribed, as catarrh of the bronchia and urinary passages, its medicinal use is now almost entirely restricted to forming a solution in ether with which cotton may be saturated for the purpose of filling *carious teeth* and protecting their tender surface from the influence of cold and the contact of food during mastication. *Sandarac* may be employed in a similar manner. A solution of mastic in alcohol may be applied to arrest *bleeding* from leech-bites and other slight wounds. Mastic is an ingredient of the "dinner pill" (*Pil. aloes et mastiches*). At a time when Chian turpentine was supposed to be a remedy for uterine cancer, mastic was substituted for it with equally negative results (*Med. Record*, xviii. 518).

MATICO, U. S.—MATICO.

Maticæ folia, Br.—*Feuilles de matico*, Fr.; *Maticoblätter*, G.

The leaves of *Artanthe elongata*, *Miquel*, s. *Piper elongatum*, *Vahl*, s. *P. angustifolium*, *Ruiz et Pavon*, s. *Steffensia elongata*, *Kunth*. Bentley and Trimen, *Med. Plants*, 242.

Nat. Ord.—Piperacæe.

Origin.—A shrubby plant about 8 feet (2.4 M.) high, sometimes cultivated, and found in moist woods of tropical America from Mexico southward to Venezuela, Brazil, and Peru. The minute yellowish flowers are very numerous, aggregated into a solid, cylindrical, slender spike about 6 inches (15 Cm.) long, and produce blackish fruits of the size of a poppy-seed.

FIG. 181.

Matico-leaf.

Description.—The leaves, which are very frequently mixed with branches and spikes of flowers or fruits, are rather thick, about 6 inches (15 Cm.) long, oblong-lanceolate, very finely serrulate, narrowed at the apex to a blunt point, heart-shaped, and somewhat unequal at the base, having a very short petiole. The upper surface is nearly glabrous, of a green color, and very uneven or tessellated in appearance from the depressed veins, which are prominent beneath, making the downy lower surface reticulate, the meshes being small, and the veins densely covered with brownish hairs. The leaves, particularly when rubbed between the fingers, have an aromatic odor and a warm, aromatic, bitterish taste.

Constituents.—Matico contains about 1½ per cent. of a thickish, pale-yellow, volatile oil, consisting of two oils, one of which is sometimes heavier than water. Wiegand (1846) proved the non-existence of Hodge's maticin, which is a potassium salt. Stell (1858) showed the absence of piperine and cubebin, and obtained a ruby-colored resin of a very acrid and pungent taste. Subsequently, Marcotte isolated a crystallizable acid named *artanthic acid*.

Matico contains also some tannin and other principles common to vegetables.

Substitutions.—In different parts of South and Central America the Spanish names *matico* and *yerba* or *palo del soldado* (soldier's herb or tree) are given to other plants besides the one described above—namely, to *Eupatorium glutinosum*, *Kunth* (Compositæ), and *Waltheria glomerata*, *Prest* (Sterculiaceæ), the leaves of which are likewise used for arresting hæmorrhage. The first-named species has opposite petiolate, ovate-lanceolate leaves, which are more or less heart-shaped at the base, acuminate, crenately serrate, roughish above and tomentose beneath. The leaves of the second species are ovate, serrate, rounded or subcordate at the base and soft-hairy on both sides. *Artanthe* (s. *Piper*) *lancaefolia*, *Miquel*, is similarly used in New Granada. Bentley (1864) met with the leaves of *Artanthe adunca*, *Miquel*, *Piper aduncum*, *Linne*, which were offered as matico. They are similar in shape, and the upper surface is marked by some sunken, ascending, and parallel nerves, and the lower surface by corresponding reticulations, but they have not the tessellated appearance nor the roughness and hairiness on the lower surface observed on the official matico-leaves; their properties appear to be the same.

Off. Prep.—Infusum maticæ, Br.; Extract. matico fluid., Tinct. matico, U. S.

Allied Products.—PIPER BETLE, *Linne*—Betel, E., G.; Bétel, Fr.—It is a climbing shrub, indigenous to India and cultivated in various tropical countries. The leaves are about 5 inches (12 Cm.) long, broadly ovate, acuminate, obliquely cordate at the base, five- to seven-nerved, coriaceous, and above glossy. They have a burning aromatic and bitter taste, and are largely employed by the Malays for chewing with slaked lime and scrapings of the areca-nut (p. 256).

PIPER CARPUNYA, *Ruiz et Pavon*. A small tree indigenous to Chili and Peru, the leaves of which are used. They are about 4 inches (10 Cm.) long, cordate-ovate, acute, coriaceous and glossy, and when dry have an agreeable odor, and are used in affections of the digestive organs.

PIPER PELTATUM and P. UMBELLATUM, *Linne*. Both plants are known in some parts of tropical America as *caapaba*, in others as *periparabo*: the roots are used as diuretics and the leaves in skin diseases and tumors. The rhizome is tuberos, about ½ inch (2 Cm.) thick, with dark-brown woody rootlets about ½ inch (5 Mm.) thick and containing reddish oil-glands.

PIPER METHYSTICUM, *Forster*. It is a shrub, with cordate, acuminate, and many-nerved leaves, indigenous to the Sandwich and other islands of the Pacific Ocean. The root is the part employed, and is known as *ava* and *kava-kava*. It is large, woody, but spongy and light, has a thin grayish-brown bark, and a medullium consisting of a yellowish or yellow, occasionally pale-reddish, cellular tissue, and of numerous radiating linear wood-bundles. It has an agreeable odor, recalling that of lilac and of meadow-sweet, and a faintly pungent and slightly bitter taste. Cuzent (1860) found in the root some volatile oil of a lemon-yellow color, a large amount of starch, an acrid resin, and a principle called *kavahen* or *methysticin*, which crystallizes in needles on con-

centrating the tincture of kava-root, and is purified by treatment with animal charcoal and recrystallization from alcohol. It is colorless, tasteless, fusible above 120° C. (248° F.), sparingly soluble in cold water, and readily soluble in alcohol and ether. The masticated root, subjected to fermentation, yields an intoxicating beverage called *kava*.

Medical Action and Uses.—In its nature and operation matico closely resembles the terebinthinate medicines, while its odorous and special stimulant qualities rank it with cubeb and copaiva. Like these substances, it is absorbed into the blood, and appears to produce a constriction of the capillary vessels, whereby it controls mucous fluxes and hæmorrhages, while it occasions more or less diuresis. It has been employed, like copaiva, in the treatment of *bronchitis*, *gonorrhœa*, *leucorrhœa*, *vesical catarrh*, *incontinence of urine*, and *chronic diarrhœa* and *dysentery*, and in hæmorrhage from the *lungs*, *stomach*, *bowels*, *rectum*, and *kidneys*. Like oil of turpentine, it has been used as a topical hæmostatic. The *dose* of the powder is from $\frac{1}{2}$ drachm to 2 or 3 drachms (Gm. 2–12) several times a day. An extract has been made, of which the dose is from 60 to 75 grains (Gm. 4–5). The fluid extract and tincture are officinal.

Betel-leaves are chewed in Malabar, as above stated, and it is said that in Java their juice is used to cure obstinate and dry coughs. The inhabitants of the Fiji Islands employ *Piper methysticum* to prepare a drink which has several of the qualities of tea and coffee, being refreshing and stimulating, but not intoxicating. It augments the secretion of saliva, and hence is much prized for relieving the thirst incident to a hot climate. It, however, impairs the muscular power, so that they who indulge in it are apt to walk with a staggering gait, although the mind remains perfectly clear. It does not raise the temperature, and only influences the pulse by steadying it. It constipates the bowels, and its long-continued and excessive use is said to impair the eyesight and to produce leprous ulcers all over the body. Mr. Kesteven, from whom these statements are derived, mentions that the chief medical use of kava is to cure chronic *cystitis* and *gleet* (*Practitioner*, xxviii. 199). A similar account of its medicinal properties is furnished by Dupuy, who also states that it is a diuretic and a stomachic tonic (*Med. Record*, xvi. 106). Its stimulating and diaphoretic action caused it to be used by the South Sea Islanders in the treatment of *sypilis* (Strumpf).

MATRICARIA, U. S.—GERMAN CHAMOMILE.

Flores chamomillæ, P. G.; *Flores chamomillæ vulgaris*.—*Fleurs de camomille commune* (d'Allemagne), Fr.; *Kamille*, *Kamillenblumen*, G.

The flowers of *Matricaria* (*Chrysanthemum*, *Bernhardi*) *Chamomilla*, Linné, s. *Chamomilla officinalis*, Koch. Bentley and Trimen, *Med. Plants*, 155.

Nat. Ord.—Compositæ, Senecionideæ.

Origin.—An annual herb, with a branching stem about a foot (30 Cm.) high, smooth, twice- or thrice-pinnatifid leaves, with spreading setaceous segments and numerous flower-heads terminating the slender branches. The plant is common in fields and waste places throughout Europe as far north as Finland, and in the temperate parts of Asia; it has been completely naturalized in Australia, and is occasionally cultivated in German settle-

FIG. 182.

Matricaria: a, flower-head; b, involucre; c, receptacle and involucre; d, longitudinal section of receptacle, with disk-florets; e, ray-floret; f, disk-floret; g, stamens and style of disk-floret.

ments in the United States. The flowers appear from May till August; on drying, from 20 to 25 per cent. of the drug is obtained. About 140,000 pounds of chamomile- (*Anthemis*) and German chamomile-flowers were imported in 1882.

Description.—The flower-heads are $\frac{1}{2}$ to $\frac{3}{4}$ inch (12–18 Mm.) broad, and have a flat-

tish involucre, with two or three rows of small, oblong-linear, obtuse scales having the margin membranous. The receptacle is at first convex, but becomes strongly conical and hollow, and is free from chaff. The ray-florets are about fifteen in number, soon reflexed, white, ligulate-oblong, with two notches at the apex and enclosing the bifid style, but no stamens. The numerous yellow disk-florets are tubular, five-toothed, somewhat glandular, hermaphrodite, and have the anthers united into a tube through which the bifid style projects. The akenes are small, curved, finely five-ribbed on the inner surface, brownish, without pappus, but with a slightly elevated margin at the apex. German chamomile-flowers have a peculiar aromatic odor and a bitterish aromatic taste. They are easily distinguished from allied composite plants by their smooth, conical, and hollow disks, which shrink very considerably on drying.

Constituents.—German chamomile-flowers contain about $\frac{1}{4}$ per cent. of volatile oil, some bitter extractive, malates, tannates, and a little tannin, besides the principles common to vegetables. Patton's *anthemis acid*, isolated (1859) from *Anthemis arvensis*, Linné, was obtained by Werner (1867) from the officinal flowers by exhausting them with hot water acidulated with acetic acid, concentrating, precipitating with alcohol, evaporating the filtrate, and treating with chloroform. It is described as colorless silky needles having an agreeable odor of chamomile, a strongly bitter taste, and dissolving in water, alcohol, ether, and chloroform. The precipitate obtained with alcohol is stated to contain a tasteless crystalline principle, *anthemidin*, which is insoluble in alcohol, ether, and chloroform, but soluble in acetic acid.

The volatile oil, *OLEUM CHAMOMILLÆ ÆTHEREUM*, is a dark-blue, in thin layers transparent, thickish liquid, which gradually turns green and brown when exposed to light and air, and more rapidly if obtained from dried flowers; it has a strong odor of the flowers and a warm, aromatic taste; dissolves in about 8 parts of 80 per cent. alcohol, has the specific gravity 0.93, and seems to consist of a terpene, $C_{10}H_{16}$, associated with $C_{10}H_{18}O$. The volatile oil becomes dark-brown or green with strong or diluted nitric acid, and deep red-brown with sulphuric acid. The blue color is due to the presence of a volatile principle which was named *azulene* by Piesse and *carulein* by Gladstone (1863), and which, according to both investigators, is present in all other volatile oils having a blue or green color—in the latter associated with a yellow principle.

An oil of German chamomile, containing oil of lemon, is still sometimes met with in our market; it was formerly officinal in Europe as *Olum chamomillæ citratum*, and, according to the late Prussian Pharmacopœia, prepared by adding to 480 parts of recently-collected flowers 1 part of oil of lemon, and then distilling with water; it has a deep-blue color, but is more limpid than the pure oil and more prone to change in color.

Pharmaceutical Preparations.—*OLEUM CHAMOMILLÆ INFUSUM* is employed externally, and made like oleol of anthemis (p. 209); it has a yellowish-green color.

SYRUPUS CHAMOMILLÆ. Prepare an infusion from 3 parts of German chamomile with sufficient hot water to obtain 10 parts of filtered liquid, and dissolve in this 18 parts of sugar.—*P. G.* 1872.

Medical Uses.—German chamomile has less agreeable qualities than English chamomile (*Anthemis*), but medicinally may be substituted for it.

MEDEOLA.—MEDEOLA.

The rhizome of *Medeola* (*Gyromia*, *Nuttall*) *virginica*, Linné. Meehan, *Native Flowers*, ii. 157.

Nat. Ord.—Liliacæ.

Origin.—The *medeola* or *Indian cucumber* grows in damp soil in woods and shady places of the United States east of the Mississippi, and flowers in May and June. It has a slender stem, about 18 inches (45 Cm.) high, beset with a deciduous fine wool, and bearing above its middle a whorl of six or eight spreading oblong-lanceolate leaves, which are about 3 inches (75 Mm.) long, and acute at both ends. Near the top is a whorl of three or four smaller ovate pointed leaves, and above them three or four greenish-yellow recurved flowers having six sepals and stamens, and producing a purplish-blue three-celled berry, each cell containing about five triangular seeds.

Description.—The rhizome is horizontal, 1 or $1\frac{1}{2}$ inches (25–38 Mm.) long, about $\frac{1}{2}$ inch (6 Mm.) thick, pointed at the lower end, beset with hair-like simple rootlets, pale brown-yellowish externally, white internally, and with few small wood-bundles. It is without odor, and has a sweetish, in the fresh state somewhat cucumber-like, taste. Its constituents, among which is starch, have not been investigated.

Medical Action and Uses.—Nothing appears to have been added for many years to the scanty knowledge originally possessed of this root—viz. that it was reputed to be hydragogue and diuretic, and therefore useful in *dropsies*.

MEL, U. S., Br.—HONEY.

Miel, Fr.; *Honig*, G.

A saccharine secretion deposited in the honey-comb by *Apis mellifica*, *Linné*, the hive bee.

Class Insecta; Order Hymenoptera.

MEL DESPUMATUM, U. S.—CLARIFIED HONEY.

Mel depuratum, Br., P. G.—*Miel despumé*, *Mellite simple*, *Sirap de miel*, Fr.; *Gereinigter Honig*, G.

Origin.—A saccharine liquid is secreted by the nectaries of flowers and collected by the working bees in their so-called honey-bags, where it probably undergoes some changes before it is disgorged again in the hive. Evidently, the source from which it has been collected by the bees must exert considerable influence on its flavor, and it may even contain injurious principles when the flowers of poisonous plants have been frequented by the bees; to this cause at least have been referred cases of poisoning which occurred after partaking of honey. It has been stated that honey-bees introduced into Australia ceased to produce honey after the first year, probably because in that climate they could collect the necessary food during the entire year. Honey is largely produced in Europe and North America; much that is used in the United States is imported from the West Indian Islands, and recently a well-flavored honey from California has been introduced in the Atlantic States. The importation amounted in 1878 to 24,515 gallons, and in 1882 to 69,932 gallons.

Preparation.—The finest honey, called virgin honey, is obtained simply by draining the comb; when pressure or heat is used a darker-colored product is obtained. The yield of a hive is about 15 to 20 pounds. (See paper by B. F. Creighton in *Amer. Jour. Pharm.*, 1875, p. 487.)

Clarification.—Honey a convenient quantity; heat it by means of a water-bath, remove the scum, and strain.—U. S.

The object of clarification is to remove the wax and other impurities of honey, which rise to the surface when the honey is kept for a while in the condition of a thin fluid by exposing it to the heat of a water-bath. The British Pharmacopœia directs it then to be strained through flannel previously moistened with water. The French Codex dissolves 4 parts of honey in 1 part of water, heats the mixture, removes the scum, clarifies with paper pulp, strains, and evaporates to the proper density; all preparations of honey are directed to be clarified merely by the use of paper pulp. The German Pharmacopœia of 1872 ordered honey to be diluted with twice its weight of water, heated to 100° C. (212° F.) for 1 hour, filtered, and evaporated. Various other methods have been suggested, among which may be mentioned the following: To dilute the honey with some water, add white of egg, heat gradually up to near boiling, strain and concentrate; or, to add to 28 pounds of honey, diluted with water, a little (3 drachms) gelatin, heat, and exactly precipitate the gelatin by (1 drachm) of tannin; or to treat the diluted honey with prepared chalk, or with animal charcoal, or with both, or with aluminium hydrate, or with Irish moss, or to interrupt the boiling repeatedly for about a minute by the addition of sufficient cold water, and after filtration to concentrate to the proper consistence. The long-continued heat necessary for concentrating diluted honey impairs its aroma and imparts to it a darker color; the use of tannin is objectionable, since traces of it are likely to remain behind and render the honey unfit for use with salts of iron. In our experience the first two processes give quite satisfactory results, though the product is never absolutely transparent—a result aimed at by the other processes.

Properties.—When recently prepared, honey is a translucent or nearly transparent, pale-yellowish or brownish, thick, syrupy liquid, which, on keeping, separates a granular deposit, and is ultimately changed into a crystalline mass intermixed with some liquid. It is stated that California honey gathered in May becomes granular in a few days, but if taken later in the season remains liquid for a long time. It has a slight acid reaction, an agreeable odor, varying more or less from causes mentioned above, and a sweet taste, followed by a slight acidity. E. Dietrich (1877) ascertained that, by dialyzing honey

into water the dialyzed portion, on concentration, had a golden-yellow color and a remarkably fine floral odor, while the residue upon the dialyzer was destitute of honey odor and had a sweet but insipid taste. In some parts of Africa a brown, and even greenish, honey has been observed, which may be produced by different species of *Apis*. Clarified honey has the same properties, except that it is more transparent, and has the specific gravity 1.30 *P. G.*, 1.27 *F. Cod.*; neither the U. S. nor the Br. Pharmacopœia indicates the density, which for our climate ought not to be below 1.38.

Honey dissolves readily in water, also in diluted alcohol, yielding in both cases slightly turbid solutions which have a faint acid reaction. A mixture of honey with 2 parts of water should have a specific gravity between 1.101 and 1.115 (*U. S.*); which permits the density of the honey to vary between 1.38 and 1.44.

Constituents.—The odor of honey is doubtless due to a minute quantity of volatile oil, which, according to Calloud, is intimately associated with a yellow coloring matter, *melichroin*, separated by the nectaries and bleached on exposure to sunlight. Small quantities of wax and gummy matter are usually present, and A. Vogel (1882) found in crude honey about .1 per cent. of formic acid, which appears to preserve it from decomposition; but the main constituents are *grape-sugar* or *dextrase* and *fruit-sugar* or *levulose*, of each of which from 32 to 42 per cent., or a total of about 72 to 78 or 80 per cent., is present. The honey of an American wasp, *Polybia apicipennis*, according to Karsten, contains a little cane-sugar, and the same may be the case with honey from other sources; this constituent, however, is gradually changed to *invert-sugar*, which is a mixture of grape- and fruit-sugars. It is the grape-sugar which renders honey granular, while the fruit-sugar remains liquid; the former turns polarized light to the right, the latter to the left. The albuminates, mucilaginous matter, pollen, and wax present in honey vary between about 0.5 and 1 or 2 per cent.; the ash left on incineration is generally between .12 and .16 per cent., and, according to Hager, should not exceed .5 per cent.

Adulterations.—The coarse adulteration with starchy substances is easily recognized in the soluble matter left on treating with alcohol, and by the blue color produced on the addition of solution of iodine. Adulterations with artificial grape-sugar prepared from starch by boiling with sulphuric acid are difficult to establish; aside from the physical properties, the presence of soluble sulphate (of calcium) affords the best criterion. Beet-root molasses contains chlorides, and if used for adulterating honey causes a white precipitate with silver nitrate. Starch-paste, added with the view of rendering honey thick, is deposited as a jelly-like, stringy mass on dilution with water. Neither crude honey nor honey clarified by the process of the U. S. P. yields with water an absolutely clear solution. The tests given by the pharmacopœias are as follows: "If 1 part of honey be dissolved in 4 parts of water, a clear solution should result, which should not be rendered more than faintly opalescent by a few drops of test solution of nitrate of silver (chloride) or of nitrate of barium (sulphate). If a small portion of honey be diluted with 1 volume of water and then gradually mixed with 5 volumes of absolute alcohol, it should not become more than faintly opalescent, and should neither become opaque nor deposit a slimy substance at the bottom and along the sides of the test-tube (starch, dextrin). When incinerated in small portions at a time in a platinum crucible, it should not leave more than 0.2 per cent. of ash (any larger percentage of ash and failure to respond to the preceding tests indicating the presence of glucose or other foreign admixtures). Water boiled with honey and allowed to cool should not be rendered blue or green on the addition of test solution of iodine (absence of starch)."—*U. S.* "If mixed with an equal bulk of ammonia-water, the color of honey should not be altered (absence of turmeric, aniline colors, etc.)."—*P. G.*

Pharmaceutical Uses.—Clarified honey is used as an excipient for some *pill masses* and *confections*, as the basis of *mellita* and *argymellita*, and as an ingredient in *Massa ferri carbon.*, *U. S.*

MELLITA.—Medicated honeys, *E.*; Mellites, *Fr.*; Honige, *G.*—These are simply mixtures of honey with certain medicinal substances. Owing to their proneness to change, the number of these official mixtures has been considerably diminished, and with but few exceptions none are kept on hand, but are prepared extemporaneously when required by the physician.

OXYMELLITA.—Oxymels, *E.*, *Fr.*; Sauerhonige, *G.*—are medicated honeys containing acetic acid. (See **OXYMEL**.)

Medical Action and Uses.—Honey is one of the most ancient of medicines, and its nutritious qualities were always well known. Medical history shows that the Greeks and Arabians were well acquainted with its uses and the noxious qualities of certain kinds

of it. Honey may be used with other food without any unpleasant effects in most instances, but there are persons who cannot take even a small quantity of it without feeling the head heavy or confused, while in others it causes flatulence or diarrhœa. Among the plants which are frequented by bees producing poisonous honey are *Nerium oleander*, *Azalea pontica*, *Daphne mezereum*, *Aconitum*, and *Kalmia latifolia*. The last, or mountain-laurel, is the chief source of poisonous honey in this country. The symptoms it produces are dimness of sight, vertigo, a mild or furious delirium, abdominal pain, vomiting and purging, perspiration, convulsions, foaming at the mouth, and, in a few instances, death. In some cases an eruption also appears upon the skin, and there is soreness of the throat with hoarseness of the voice.

Anciently, honey was employed for most of the medicinal purposes for which sugar is now used, and especially with barley-water for bronchial affections and sore throats. Its present use is almost exclusively local and for the same purposes as of old, and particularly to stimulate mucous surfaces, and even cutaneous sores, when their condition denotes impaired vitality. It is habitually employed in gargles to cure *aphthæ*, *thrush*, and *pseudomembranous deposits*, but its efficacy is increased by the addition of muriatic acid, borate of sodium, chlorate of potassium, etc. Honey of rose is official. Borate of sodium, in the proportion of 60 grains to an ounce of honey, is a very convenient application to *aphthæ*, etc. of the female genital organs. Honey is sometimes used as an ingredient of poultices for *boils* and *carbuncles*, as an application to *fissures of the nipple*, etc., and is applied in plasters to the *mammæ for drying up the milk*.

In this connection it may be mentioned that *propolis*, a resinous exudation with which bees cover the bottom of their hive, is reported to be beneficial in the treatment of acute and chronic *diarrhœa*.

MEL BORACIS, Br.—BORAX HONEY.

Mel sodii boratis, U. S. 1870.—*Honey of borate of sodium*, E.; *Mellite de borax*, *Miel boraté*, Fr.; *Boraxhony*, G.

Preparation.—Take of Borax, in fine powder, 60 grains (2 parts); Glycerin 30 grains (1 part); Clarified Honey 480 grains (16 parts). **Mix.**—Br.

Uses.—It is made extemporaneously, and is applied to most of the local affections enumerated in the last article.

MEL ROSÆ, U. S.—HONEY OF ROSE.

Mel rosatum, P. G.; *Mellitum rosatum*.—*Mellite de roses rouges*, *Miel rosat*, Fr.; *Rosenhony*, G.

Preparation.—Red Rose, in No. 40 powder, 8 parts (2 oz. av.); Clarified Honey 92 parts (23 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (25 oz. av. or 17½ fluidounces). Moisten the powder with 2 parts (½ oz.) of diluted alcohol, pack it firmly in a conical glass percolator, and gradually pour diluted alcohol upon it until 33 parts (8½ oz. av. or 8 fluidounces) of percolate are obtained. Reserve the first 3 parts (¾ oz. av. or 5½ fluidrachms) of the percolate, evaporate the remainder, by means of a water-bath, to 5 parts (1¼ oz. av. or 9 fluidrachms), add the reserved portion, and mix the whole with the clarified honey.

This process is essentially the one recommended by I. J. Grahame (1859), and aims to preserve in the reserved portion the main quantity of the little volatile oil present in the rose-petals. The French Codex directs the rose to be infused in 6 parts of water, the infusion to be strained, mixed with 6 parts of honey, and the mixture to be evaporated by means of a water-bath to the density 1.27. The German Pharmacopœia requires the infusion from 1 part of pale rose to be evaporated to a syrupy consistence, this to be mixed with five times its weight of alcohol, and the filtrate with 10 parts of clarified honey, the whole to be evaporated to 10 parts.

Medical Uses.—Its agreeable flavor and slight astringent and stimulant virtues render it a very pleasant and useful addition to water as a mouth-wash and gargle in cases of *sore mouth* and *sore throat*, or it may be applied undiluted to the affected part. It is a convenient vehicle for the administration of aromatic sulphuric acid and other acids.

MELILOTUS.—MELILOT.

Herba (Swimitates) meliloti. P. G.—Sweet clover, E.; *Mélilot*, Fr.; *Steinklee*, *Melilotenklee*, G.

Nat. Ord.—Leguminosæ, Papilionaceæ.

The leaves and flowering branches of *Melilotus officinalis*, *Desrousseaux* (Mel. *arvensis*, *Walbroth*, Mel. *diffusa*, *Koch*), and of Mel. *altissimus*, *Thouilliers* (Mel. *officinalis*, *Willdenow*, Mel. *macrorrhizus*, *Persoon*).

Origin.—Both plants are indigenous to Europe, the first species having an ascending stem 20 to 40 inches (0.5–1 M.) long, and growing in dry fields and along roadsides; its pale-yellow flowers have a short carina and produce obovate, transversely-wrinkled, mostly one-seeded legumes. The second species has been naturalized in the United States, grows in meadows and damp places, has an erect stem 3 to 5 feet (0.9–1.5 M.) high, the flowers bright yellow, with the carina as long as the standard and wings, and the legume obliquely oval, pointed, pubescent, reticulately wrinkled, and two-seeded. Both plants flower from July to September, and on drying acquire an agreeable odor of coumarin.

Description.—The stipules are entire, awl-shaped; the petiolate trifoliate leaves have oval or obovate-oblong leaflets, the lower ones notched, the upper ones truncate at the apex, entire near the base, and somewhat sharply serrate above, about $\frac{1}{2}$ to $1\frac{1}{4}$ inches (2 to 3 Cm.) long; the flowers are in spreading or ascending racemes, and the reflexed legumes are brown or blackish. The drug has a strong agreeable odor and a bitterish, aromatic, and somewhat pungent taste.

Allied Plant.—MELILOTUS ALBUS, *Desrousseaux* (M. *vulgaris*, *Willdenow*). White melilot is indigenous to Europe and naturalized in the United States; it resembles the preceding species, but has white flowers, the petals of which are unequal, the standard being longest.

Constituents.—The odorous principle was observed by Vogel (1820), and supposed to be benzoic acid. Guillemette (1835) proved it to be identical with Guibourt's *coumarin*, obtained from tonka beans, and which exists also in some rubiaceous plants. (See GALIUM.) It may be prepared by exhausting the herb with strong alcohol, distilling off most of the solvent, separating the fat, crystallizing, and purifying by recrystallization from alcohol. Coumarin, $C_9H_6O_2$, which has since been isolated from many odorous plants (see pp. 721 and 880), crystallizes in colorless shining prisms, which fuse at 67° C. (152.6° F.) and are readily soluble in fixed and volatile oils, alcohol, and hot water. It was obtained artificially by W. H. Perkin (1867) by treating salicyl aldehyd with sodium, and decomposing the compound with acetic anhydride. When treated with sodium amalgam it is converted into *melilotic* and *coumaric* acids, which are also present in the herb, sometimes in combination with coumarin. Both acids are crystallizable, and have a bitter taste. Melilotic acid, $C_9H_{10}O_3$, fuses at 82° C. (179.6° F.), and its salts, when strongly heated, yield phenol. Coumaric acid, $C_9H_8O_3$, is also obtained from coumarin by boiling it with concentrated potassa solution: it fuses at 195° C. (383° F.), and the solutions of its salts are fluorescent.

TONKA BEANS, *E.*, *Fève tonka*, *Fr.*, Tonkabohnen, *G.*, are the seeds of a papilionaceous tree of Guiana, *Dipteryx* (Coumarouna, *Aublét*) odorata, *Willdenow*. They are nearly 2 inches (5 Cm.) long, somewhat two-edged, deeply wrinkled, blackish-brown, of a fatty lustre, and usually covered with a crystalline efflorescence of coumarin. The so-called English tonka beans, from *Dip. oppositifolia*, *Willdenow*, are smaller, about an inch (25 Mm.) long, smoother, and contain less coumarin.

Pharmaceutical Preparation.—EMPLASTRUM MELILOTI. Melt together 4 parts of yellow wax and 1 part each of turpentine and olive oil, and while cooling add 2 parts of powdered melilot.—P. G. 1872.

Medical Action and Uses.—The peculiar odor of melilot, which is closely analogous to that of tonka bean, of vanilla-grass, etc., as well as its active properties, are attributed to a proximate principle, coumarin. Given to dogs in the dose of from 7 to 10 grains, this substance produced great and even fatal depression, and in man in the dose of from 30 to 60 grains it occasioned nausea, giddiness, depression, vomiting, and drowsiness. In Europe melilot is sometimes mingled with hay to stimulate the appetite of cattle; it is strewn among clothing and furs to protect them from moths, and is mixed with snuff to scent it. Formerly it was used in a variety of disorders, including colic, diarrhœa, dysury, dysmenorrhœa, and rheumatism, but at present it is only applied externally, in decoction or infusion or in plasters or ointments, to allay local pains, especially in the abdomen and joints. The liquid preparations named are made with from half an ounce to an ounce of the flowering-tops in a pint of water (Gm. 16–32 to Gm. 500).

MELISSA, U. S.—MELISSA.

Folia (Herba) melissæ, P. G.—*Balm, Lemon balm*, E.; *Mélisse, Céline, Herbe au citron*, Fr.; *Melissenblätter, Citronenkraut*, G.

The leaves and tops of *Melissa officinalis*, Linné.

Nat. Ord.—Labiatae, Satureieae.

Origin.—Balm is a perennial herb, from the woody root-stock of which a number of branching, pubescent stems, 2 to 4 feet (0.6–1.2 M.) high, are produced. The plant is indigenous to Western Asia and Southern Europe, has become naturalized to some extent in the United States, and is not unfrequently cultivated. The variety *a. citrata*, Bischoff, or lemon balm, is generally preferred, and is alone recognized by some of the European pharmacopœias. On drying, the fresh leaves lose about 75 per cent. of their weight.

Description.—The leaves are 1½ to 2 inches (3–5 Cm.) long, petiolate, ovate, with a rounded or somewhat heart-shaped base, coarsely crenate-serrate at the margin, obtusely pointed at the apex, the upper surface with scattered hairs, the lower surface glandular in the axils of the nerves. The upper leaves are smaller, often softly pubescent on both sides, and at the base rather wedge-shaped. The axillary cymules are about four-flowered; the calyx is hairy, tubular-bell-shaped, with the upper lip three-toothed and the lower two-cleft. The milk-white or pale-purplish corolla has the tube curved upward, the upper lip notched and the lower lip three-lobed, with the lowest lobe largest; the stamens are four in number, the lower pair longer, all converging toward the upper lip. The dried herb has a mild agreeable odor, in the variety mentioned above somewhat like that of lemon; the taste is slightly bitter.

Melissa cordifolia, Persoon, is indigenous to Southern Europe, where it is sometimes medicinally employed; the leaves are larger and more woolly, and have a rather disagreeable odor; the plant is now regarded as a mere variety of *M. officinalis*.

Adulterations are not likely to be met with. The leaves of *Nepeta cataria*, Linné, var. *β. citriodora*, have an odor resembling that of lemon balm, but they are cordate-ovate, of a gray-green color, soft-downy above and tomentose beneath, and by these characters are easily distinguished from melissa.

Constituents.—The leaves contain, besides the common constituents of plants, a small quantity of tannin and bitter principle and about ½ to ¾ per cent. of volatile oil, which is colorless or yellowish, has a spec. grav. of about 0.89, dissolves in about 5 parts of alcohol spec. grav. 0.85, and contains a stearopten.

Pharmaceutical Preparations.—AQUA MELISSÆ, P. G. Take 1 part of balm-leaves and sufficient water; distil 10 parts.

SPIRITUS MELISSÆ COMPOSITUS.—Compound spirit of balm, E.; Eau des Carmes, Fr.; Karmelitergeist, G.—Take of balm 14 parts; lemon-peel 12 parts; nutmeg, 6 parts; cinnamon and cloves, each 3 parts; alcohol 150 parts; and water 250 parts; distil 200 parts.—P. G. The French Codex gives a similar formula, and directs for the above quantity of spirit nearly 2 parts each of coriander and angelica in addition to the other ingredients.

Medical Uses.—Balm tea is a popular and refreshing drink when made with the fresh plant and taken cold. A hot infusion of the dried plant (Gm. 5–10 in Gm. 100) is one of the mildest that can be used to favor the operation of diaphoretic medicines.

MENISPERMUM, U. S.—MENISPERMUM.

Canadian moonseed, Yellow parilla, E.; *Ménisperme du Canada*, Fr.; *Canadisches Mondkorn*, G.

The rhizome of *Menispermum canadense*, Linné.

Nat. Ord.—Menispermaceæ.

Origin.—This is a North American climber, with peltate, roundish-cordate, and angular leaves, small clusters of greenish-yellow flowers, and black, glaucous, roundish kidney-shaped drupes. The rhizome was formerly brought into commerce as *Texas sarsaparilla*, and its botanical source was established by R. P. Thomas (1855).

Description.—The rhizome is several feet long, about ¼ inch (6 Mm.) thick, of a yellowish-brown color, cylindrical when dry, with numerous fine longitudinal wrinkles, and beset with thin branching rather brittle rootlets. Internally it is yellowish, breaks with a tough fibrous fracture, and exhibits on transverse section a bark of about one-tenth the diameter of the rhizome and composed of two distinct layers, a woody zone consisting of about fourteen rather broad porous wood-wedges separated by medullary rays of nearly

the same width, and a large central pith. The rhizome has a slight odor and a bitter taste.

Constituents.—We found (1863) the rhizome to contain a small quantity of berberine and a larger proportion of a white alkaloid, which has a bitter taste, neutralizes acids completely, and yields precipitates with the group reagents for alkaloids. H. L. Barber (1884) found this alkaloid to differ from oxyacanthine and menispermine, and to be insoluble in benzol and alkaline liquids; it dissolves in 75 parts of water, in 6 parts of alcohol, in 40 parts of ether, and in 20 parts of chloroform, and gives with sulphuric acid a brown color, gradually fading; with nitric acid, a yellow color; and with fused zinc chloride, a brownish-yellow color. We propose for this alkaloid the name *menispermine*. The rhizome also contains starch, gum, resin, tannin, and other common constituents of plants.

Medical Action and Uses.—It has been reputed for many years that menispermum is tonic, alterative, and diuretic, and that its medicinal qualities are similar to those of sarsaparilla. It much more probably resembles calumba, not so much because, like that medicine, it yields berberine, as because it is bitter. We read that it is used in *scrupulous* affections as a substitute for sarsaparilla, but without the assurance that the latter medicine is itself of demonstrable utility in their treatment. Whatever virtues it may possess await discovery by intelligent investigation.

MENTHA PIPERITA, U. S.—PEPPERMINT.

Folia (Herba) menthæ piperitæ, P. G.; *Menthe poivrée*, Fr.; *Pfefferminze*, G.

The leaves and tops of *Mentha piperita*, *Linneé*. Bentley and Trimen. *Med. Plants*, 203.

Nat. Ord.—Labiatae, Satureiæ.

Origin.—Peppermint is a perennial plant, readily multiplying by runners, and with a square frequently purplish stem, about 3 feet (90 Cm.) high. Its native country is unknown; it is regarded as a mere variety of *M. hirsuta*, *Linneé*, with which it is connected by many intermediate forms, and from which it was probably produced by cultivation. It is now found wild in wet places in England, in other countries of Europe, and in North America; it is largely cultivated. It flowers in August and September. The moisture of the fresh herb amounts to about 80 per cent.

Description.—The leaves are 2 to 3 inches (50–75 Mm.) long, and all petiolate, the petioles being about $\frac{1}{2}$ inch (12 Mm.) long; they vary in shape between lanceolate and

FIG. 183.

Mentha piperita, *Linneé*: flower and corolla cut open, magnified 8 diameters.

ovate-lanceolate, have a rounded base, an acute apex, and a sharply serrate margin; the upper surface is dark-green and smooth, the lower surface paler with numerous glands, and upon the nerves sparingly pubescent. The inflorescence is terminal, and consists of twelve to sixteen whorls, the lowest of which are somewhat distant; it is conical in shape, rounded or somewhat acute above, and 2 inches (5 Cm.) long; the cymules of each whorl contain about twenty or thirty flowers. The calyx is often purplish, tubular, five-toothed, ten-ribbed, glabrous, but dotted with yellowish glands. The corolla is pale purplish-red and smooth,

with the tube about as long as the calyx, and the limb nearly equally four-lobed, and the upper lobe emarginate. The four short stamens are equal in length, and included in the tube. The fruit consists of four brownish smooth or rugose akenes. The herb has a strong peculiar aromatic odor and a pungent and cooling taste.

Several varieties are known, differing in the width of the leaves, the amount of pubescence, and the compactness of the flowering spikes.

Constituents.—The most important constituent is the volatile oil, to which the drug owes its odor and taste, and of which the dried herb yields in the neighborhood of 1 per cent. (See *OL. MENTHÆ PIPERITÆ*.) A little tannin and the other constituents are of no medicinal importance. (For *MENTHOL*, see pp. 1067 and 1663.)

Pharmaceutical Preparations.—SPECIES AROMATICÆ, *P. G.*—Aromatic herbs, *E.*; Espèces (Herbes) aromatique, *Fr.*; Aromatische Kräuter, *G.*—Peppermint, wild thyme, garden thyme, and lavender-flowers, of each 2 parts; cloves and cubebs, of each 1 part. Cut and bruise separately, separate the fine powder, and mix.—*P. G.* Peppermint, sage, wild thyme, garden thyme, rosemary, hyssop, origanum, and wormwood, of each 1 part.—*F. P.*

SYRUPUS MENTHÆ (PIPERITÆ).—Syrup of peppermint, *E.*; Sirop de menthe poivrée, *Fr.*; Pfefferminzsyrop, *G.*—Dissolve 60 parts of sugar in 40 parts of infusion prepared from 10 parts of peppermint, 50 parts of water and 5 parts of alcohol.—*P. G.*

Off. Prep.—Spiritus menthæ piperitæ, Vinum aromaticum, *U. S.*

Medical Action and Uses.—The name, "peppermint," describes the sharp, biting taste of this plant, whose odor when fresh is likewise very powerful, but refreshing. In the mouth it produces a pungent sensation, followed by a sense of coolness and numbness, increased by inhaling strongly. The essential oil occasions this feeling more sensibly, as well as a diffusive warmth in the abdomen, when it is swallowed. The action of peppermint is mainly that of a carminative stimulant, with a certain degree of anodyne power, which last is especially recognized by the popular use of the bruised fresh leaves to allay colic, headache, and other local pains. A hot infusion is commonly employed to relieve colic, flatulence, diarrhœa, vomiting, cholera morbus, dysmenorrhœa, and the associated abdominal pains. Nervous headache, palpitation of the heart, hiccup, and other phenomena of difficult digestion are palliated by this medicine. The hot or warm infusion, especially when made with from half an ounce to an ounce of the fresh herb to a pint of water (Gm. 15–32 to Gm. 500), is a very excellent preparation. It may be given in tablespoonful doses. Usually the water or the spirit is more convenient, given in sweetened hot water. The special virtues of the oil are described elsewhere.

MENTHA VIRIDIS, *U. S.*—SPEARMINT.

Herba menthæ acutæ (vel romanæ).—Menthe verte, Menthe romaine, Baume vert, *Fr.*; Grüne Minze, Römische Minze, *G.*

The leaves and tops of *Mentha viridis*, *Linné*, s. *M. sylvestris*, var. *glabra*, *Koch*. Bentley and Trimen, *Med. Plants*, 202.

Nat. Ord.—Labiata, Satureiæ.

Origin.—Spearmint is a perennial herb with a square green or sometimes purplish stem about 3 feet (90 Cm.) high, and multiplying extensively by long runners. It is probably a cultivated variety of *M. sylvestris*, *Linné*, the typical form of which has broader woolly leaves and a cylindrical or subconical inflorescence, and is frequently found in moist and swampy localities throughout the greater portion of Europe. Spearmint appears to be indigenous to England, but it is cultivated and has been naturalized in the United States and most civilized countries. It flowers from July to September; on drying, its weight diminishes from 80 to 85 per cent.

Description.—The leaves are sessile, or only the lowest with a very short petiole, 2 to 3 inches (5–7 Cm.) long, lanceolate to ovate-lanceolate, acute, serrate, smooth or sparingly hairy, and densely glandular beneath. The inflorescence is in terminal, narrow, acute spikes, with distant whorls of about fifteen to twenty flowers in each. The glandular calyx is tubular-bell-shaped, with five sharp and ciliate teeth; the corolla is light-purplish, naked, four-lobed, and bears upon its tube four long and nearly equal stamens. Spearmint has a strong aromatic odor and a warm aromatic taste, which resembles that of peppermint, but is less pungent, and scarcely cooling.

FOLIA (HERBA) MENTHÆ CRISPÆ.—Crisped (curled) mint, *E.*; Menthe crépue, *Fr.*; Krauseminze, *G.*

The German and other pharmacopœias recognize, instead of spearmint, this cultivated variety, known as *Mentha crispa*, *Linné*, which is by different botanists referred to *M. aquatica*, *M. sylvestris*, or *M. piperita*, *Linné*. The leaves are sessile or short-petiolate, smooth or somewhat pubescent, heart-shaped or roundish-ovate, acute or pointed, and sharply toothed and crisped on the margin. Other species of mint, like *M. viridis*, *sativa*, *arvensis*, and *rotundifolia*, *Linné*, frequently produce in cultivation forms with crisped leaves, and the crisped mints cultivated in different parts of continental Europe probably belong to several of these species.

Constituents.—The principal constituent of spearmint is volatile oil (see *OL. MENTHÆ VIRIDIS*); the others, like a little tannin, are of no medicinal or pharmaceutical importance.

Off. Prep.—*Spiritus menthæ viridis*, U. S.

Medical Uses.—The action of spearmint is generally described as identical in its action with that of peppermint, but it is really much less intense. Its uses are the same as those of peppermint, but its milder action has led to its being preferred for infantile cases. An infusion of spearmint may be made with the proportions mentioned under PEPPERMINT.

MENYANTHES.—BUCKBEAN.

Folia (Herba) trifolii fibrini, P. G.; *Bogbean, Marsh trefoil, Water shamrock*, E.; *Ményanthe, Trèfle d'eau (de marais)*, Fr.; *Fieberklee, Bitterklee, Dreiblatt*, G.

The leaves of *Menyanthes trifoliata*, Linné. Bentley and Trimen. *Med. Plants*, 184.

Nat. Ord.—Gentianaceæ.

Origin.—The buckbean is a perennial indigenous to North America from Pennsylvania northward and to Europe and Northern Asia. It grows in boggy places, has a fleshy rhizome of the thickness of a finger and sheathed by the remnants of the leaf-stalks, and bears a naked scape with about fifteen rose-colored or whitish flowers. It blooms in May and June. The leaves are collected in spring, and on drying lose about 80 per cent. in weight.

Description.—The leaves are on petioles 4 or 6 inches (10–15 Cm.) long, ternate, the leaflets sessile, 2 to 3 inches (5–8 Cm.) long, obtuse, oblong or obovate, entire or slightly crenate, smooth, and pale-green. They are inodorous, and have a very bitter taste, free from astringency.

Constituents.—Trommsdorff found in the leaves the principles usually present in herbaceous parts of plants, and obtained the bitter principle in the form of an extract-like mass. Brandes (1830 and 1842) succeeded in gaining it partly as a thick amorphous mass, partly in yellowish-white granules. Landerer (1839) found an ethereal extract of buckbean to contain white bitter needles, which were soluble in water and alcohol and precipitated by alkalis from their acid solution (?). Kromayer and Ludwig (1861) obtained *menyanthin*, which has probably the composition $C_{38}H_{54}O_{16}$. The following is an outline of one of the processes: The concentrated infusion is precipitated with tannin; the precipitate mixed with litharge, dried, and exhausted with alcohol. The mass left on evaporating the alcohol is washed with cold water and ether, again treated as before with tannin and litharge, the alcoholic solution passed through animal charcoal, mixed with water, and evaporated. It dries over sulphuric acid to an amorphous whitish mass, which on the application of heat softens, and at 115° C. (239 F.) is limpid and transparent. It is sparingly soluble in cold water, soluble in alkalis and alcohol, but insoluble in ether. It has a very bitter taste, and when boiled with dilute acids is resolved into sugar, a brown resin, and *menyanthol*, the latter being oily, volatile, heavier than water, and of an agreeable odor resembling that of bitter almonds. The leaves contain a pectin compound, which causes the infusion, sweetened with sugar, to gelatinize in a few days: this compound is insoluble in diluted alcohol.

Pharmaceutical Uses.—EXTRACTUM MENYANTHIS, S. TRIFOLII FIBRINI. The French preparation is the inspissated juice. In Germany it is made by hot infusion of the dry leaves with water.

Medical Action and Uses.—Water shamrock or marsh trefoil is a bitter tonic which is reputed to be also antiscorbutic, emmenagogue, and vermifuge. In large doses, like other bitters, it acts as an emetic, and some observers have attributed to it narcotic qualities. It is chiefly used in atonic *dyspepsia* and those hepatic and digestive derangements which are apt to prevail in damp malarial localities. It is a popular remedy in chronic *cutaneous eruptions*, both internally and externally. The most efficient form of the medicine is the expressed juice, which is administered in the dose of 2 or 3 ounces (Gm. 64–96) daily, in whey or thin broth. An infusion is made with half an ounce of the herb in a pint of hot water (Gm. 16 to Gm. 500) both for internal and external use.

MESEMBRYANTHEMUM.—ICE-PLANT.

Diamond fig, E.; *Glaciale, Cristalline*, Fr.; *Eiskraut*, G.

Mesembryanthemum crystallinum, Linné.

Nat. Ord.—Mesembryanthemææ.

Description.—The ice-plant is an annual or biennial growing near the sea-coast of Southern Europe and Southern Africa, and is much cultivated for ornament. It is

smooth, but covered with glittering vesicles resembling hoar-frost. The stem is about a foot (30 Cm.) long, decumbent, and has the lower leaves opposite, the upper ones alternate, varying between roundish-ovate or obovate to oblong, wavy, amplexicaul, and frequently purplish on the margin and apex. The flowers are nearly sessile, white or reddish, have numerous linear petals and stamens, and produce a five-celled many-seeded capsule. The plant is inodorous and has an unpleasant saline taste.

Constituents.—John found the expressed juice to contain 3 per cent. of solid matter, consisting of various salts and the ordinary principles of the herb. The liquid of the vesicles, according to Voelcker, contains albumen, oxalic acid, and various salts. The dry plant yielded to Brandenburg 42 per cent. of ash, of which 31 per cent. was sodium salts, the remainder being salts of earths and traces of potassium. H. Mangon (1882), on the contrary, found the ash to contain such a proportion of potassium salts that ice-plants raised on a hectare of ground would yield 863 kilos of potassium carbonate.

Medical Action and Uses.—This is an obsolete medicine which once had a certain vogue in Europe, especially for the relief of disorders of the bladder attended with *dysury* or *incontinence* of urine. The expressed juice was used in the *dose* of a table-spoonful (Gm. 16) daily.

MESENNA.—MUSENNA.

Muséna, *Moucéna*, Fr.; *Musenmarinde*, G.

Origin.—Musenna-bark has been referred by Brogniart to a tree, *Albizzia anthelmintica*, *Condou* (Nat. Ord. Leguminosæ), and by Martius and others to *Rottlera Schimperi*, *Hochstetter* (Nat. Ord. Euphorbiacæ). The bark comes from Abyssinia, and was sent to Europe about the year 1838.

Description.—Musenna-bark comes in flat or bent pieces, which are 1 or 2 inches (2-5 Cm.) broad, and sometimes 12 inches (30 Cm.) long. The outer surface is either smooth and brown-gray or uneven, fissured, and yellowish-brown, followed by a thick pale brownish-yellow granular layer, which covers the very tough and fibrous pale-yellow bast-layer. The bark is inodorous, and has, particularly in the liber, a nauseous, sweet, bitterish, and afterward persistently acid taste.

Constituents.—Thiel (1862) isolated *musemin*, which is an amorphous acid principle resembling saponin, but more soluble than this in alcohol; the bitter principle has not yet been obtained pure. Tannin appears to be absent, the infusion being colored yellow by ferric chloride. The bark yields 5½ per cent. of ash, containing much silica.

Medical Action and Uses.—It is alleged that the Abyssinians, to expel *tæniæ*, use 3 or 4 ounces (Gm. 90-120) of the powdered bark of musenna made into an electuary with honey, after fasting for 24 hours. The parasite is discharged, neither whole nor in fragments, but reduced to a sort of pulp. The medicine thus administered is apt to occasion nausea, but neither colic nor diarrhœa, and its use is followed after several hours by a purgative, usually of castor oil. When musenna has been employed in Europe it has generally failed to produce the results as a tænicide which are attributed to it in its native country.

METHYLENI BICHLORIDUM.—BICHLORIDE OF METHYLENE.

Dichlormethane, *Chloro-methyl*, E.; *Chlorure de méthyle monochloré*, *Ether chlorhydrique monochloruré de l'esprit de bois*, Fr.; *Methylenchlorid*, *Chlormethylchlorür*, G.

Formula CH_2Cl_2 . Molecular weight 84.8.

Preparation.—Methyl chloride (CH_3Cl), which is a colorless gas of an agreeable odor and sweet taste, is prepared by heating a mixture of 1 part of methylic alcohol, 2 parts of common salt, and 3 parts of sulphuric acid, and passing the gas through water into a glass globe. Chlorine gas is conducted at the same time into this globe, which is drawn out below so as to form a thin tube, passing into one tubulure of a Woulfe's bottle, the second tubulure being connected, by means of a bent glass tube, with a second Woulfe's bottle placed in ice, and this with a flask cooled by means of a freezing mixture; the liquid condensed in the Woulfe's bottles is chiefly chloroform, while that condensing in the flask will be pure methylene bichloride. This is Regnault's process, by whom the compound was discovered (1840); methyl chloride was discovered by Dumas and Peligot (1835).

Properties.—Methylene bichloride is a colorless liquid, having at 18° C. (64.4° F.)

the spec. grav. 1.344, and boiling at 30.5° C. (87° F.). The same compound, obtained by Butlerow (1859) by heating biniodide of methylene in a current of chlorine gas, boiled at 40.5° C. (105° F.). Its odor resembles that of chloroform. It has no action upon test-paper, is soluble in alcohol and ether, and scarcely affected by alcoholic solution of potassa. It is decomposed when exposed to light and air, the change being prevented by the addition of a little alcohol. Its vapor has the density 3.012 and burns with a bright flame.

In composition it may be regarded as the chloride of methylene (CH_2) or as a derivative of methyl, CH_3 ; the following shows its relation to allied compounds:

	Methyl, CH_3 .	Methylene, CH_2 .
Marsh gas	CH_3H	—
Methyl chloride	CH_3Cl	—
Methylene bichloride	CH_2Cl_2	CH_2Cl_2
Chloroform	CHCl_3	CHCl_2
Chlorocarbon	CCl_4	CCl_3

Physiological Action.—*On Animals:* Dr. Richardson found that chloride of methylene produced, though in a less intense degree, the same effects as the bichloride, which has the great advantage of being a more stable compound. When pigeons are exposed to the vapor of the latter preparation it is longer in producing anæsthesia than chloroform, the pulse and respiration are more accelerated, the insensibility more prolonged, and the recovery more sudden. In a rabbit killed by it the heart-beat and the breathing ceased simultaneously; the lungs were not congested, and both sides of the heart contained blood. Blood saturated with this bichloride is of a bright-red color, and even when defibrinated forms a clot of albumen and corpuscles.

On Man: The inhalation of the vapor is described as being very pleasant and but slightly irritating, drowsiness and unconsciousness coming on without any noise in the head or oppression, and recovery taking place at once and completely, without any sense of depression. Like chloroform, it is very apt to occasion vomiting, and like ether it sometimes causes a stage of excitement and struggling which may be difficult to subdue. Although it does not produce fatal effects as frequently as chloroform, it is not exempt from that danger. Up to 1874 at least four cases had been reported in which death was directly traceable to this anæsthetic, and in the following year a fifth occurred in London. In the last case the breathing became suddenly loud and stertorous, deep, full, and exaggerated; the lips and cheeks retained their color; the pulse at the wrist failed rapidly, and then ceased almost abruptly. A sixth case occurred at Ipswich, England, in which the stertor was preceded by rather violent struggling. Up to 1881 nine deaths were attributed to this anæsthetic, in some of which the abrupt occurrence of death seems to prove that it was due to syncope. In several, also, it followed doses of $\frac{1}{4}$ drachm (Reichert, *Amer. Jour. of Med. Sci.*, July, 1881, p. 52). A further, although a subordinate, objection to this compound is its volatility, which renders its use difficult in a hot atmosphere.

Surgical Uses.—In 1877, Mr. Spencer Wells made the following statement, which, in relation to the particular class of cases referred to, appears conclusive as to the superiority of this anæsthetic: "In 1872, I made known my opinion that all the advantages of complete anæsthesia, with fewer drawbacks, could be obtained better by the use of bichloride of methylene than by any other known anæsthetic. This was the result of the experience of five years and of three hundred and fifty serious operations. The experience of the five succeeding years, with more than six hundred additional cases of ovariectomy and many other cases of surgical operations, has fully confirmed me in this belief. Given properly diluted with air, it has, in my experience of ten years, with more than one thousand operations of a nature unusually severe as tests of an anæsthetic, proved to be, without a single exception, applicable to every patient, perfectly certain to produce complete anæsthesia, relieving the surgeon from all alarm and even anxiety, and its use has never been followed by any dangerous symptoms which could be fairly attributed to it." Other surgeons have testified to its efficiency in a great variety of surgical operations, both capital and trivial, yet, from whatever cause, it does not seem to have supplanted to any great extent either chloroform or ether. Perhaps it may be, as Mr. Wells remarks, that the fluid sold as bichloride of methylene may have been only chloroform mixed with some spirit or ether; perhaps the reason may be found in the opinions expressed by Dr. Richardson himself, that "he was not favorably impressed with the application of the bichloride to *quick* general anæsthesia," and that "it belongs to a dan-

gerous family of chemical substances, and cannot therefore be played with without risk."

The deaths above referred to have been attributed to asphyxia, but the symptoms of some of them distinctly refute that opinion; yet it is none the less imperative that in administering the vapor a sufficient proportion of atmospheric air should be admitted along with it. For this purpose a hollow cone made of pasteboard, pierced with holes, should contain the cloth or sponge upon which the liquid has been poured. The quantity used should not exceed, for a first inhalation, 30 or 40 minims; half as much may be used each time that signs of returning consciousness appear.

METHYLI IODIDUM.—IODIDE OF METHYL.

Iodure de méthyle, Fr.; *Jodmethyl*, G.

Formula CH_3I . Molecular weight 141.6.

Preparation.—This compound was first obtained by Dumas and Peligot (1835) by adding very gradually 1 part of phosphorus to a solution of 8 parts of iodine in 12 or 15 parts of methylic alcohol, agitating the distillate with water, and rectifying. According to Wanklyn (1867), iodide of potassium and anhydrous methylic alcohol are mixed in a retort in equivalent proportions; dry hydrochloric acid gas is passed into the mixture, which is then distilled, and the distillate purified as before.

Properties.—Iodide of methyl is a colorless liquid of an ethereal odor and the spec. grav. 2.199 at 0°C . (32°F). It boils at 43.8°C . (111°F), and by the aid of a wick burns with difficulty, giving off violet vapors.

Allied Compound.—METHYLENII IODIDUM, s. biniodidum, CII_2I_2 (mol. weight, 267.2), was prepared by Butlerow (1859) by acting upon iodoform with sodium ethylate. It is readily formed by heating chloroform with very concentrated hydriodic acid for several hours to near 130°C . (266°F). It is a yellow liquid having the spec. grav. 3.34, congealing to glossy scales near the freezing-point, and boiling at 180°C . (356°F), at the same time suffering partial decomposition.

Medical Action and Uses.—Proposed in 1868 by Dr. B. W. Richardson, iodide of methyl was stated to be respirable and anæsthetic when pure, but giving rise to great excitement of the heart and circulation, and when decomposed, as it was apt to become, it produced the irritating effects of iodine, including lachrymation, salivation, and bronchial secretion. In experiments upon animals inhalation of the vapor produced fatal engorgement of the bronchia. Of it Sir James Y. Simpson wrote: "I found it very powerfully anæsthetic, but dangerously so. After inhaling a very small quantity for 2 or 3 minutes I remained for some seconds without feeling much effect, but objects immediately began to multiply before my eyes, and I fell down in a state of insensibility, which continued for upward of an hour. I did not completely recover from the effects of it for some days." It was used as a local anæsthetic in cancerous and other cases, but it appears at present to have become obsolete.

MEZEREUM, *U. S.*—MEZEREON.

Mezerai cortex, Br.; *Cortex mezerei*, *Cortex thymelææ* (vel *coccognidii*).—*Mezeron-bark*, E.; *Écorce de mézéréon*, de garou, de lauréole, de thymelée, Fr.; *Seidelbastrinde*, *Kellerhalsrinde*, G.

The bark of *Daphne Mezereum*. *Linné*, *Daphne Gnidium*, *Linné*, and *Daphne Laureola*, *Linné*. Steph. and Church, *Med. Bot.*, plate 65; *Eng. Bot.*, vol. ii. plate 119; Bentley and Trimen, *Med. Plants*, 225, 226, 227.

Nat. Ord.—Thymelacæ.

Origin.—The three plants named above are small shrubs about 2 to 4 feet (0.6–1.2 M.) high. The mezeron has rose-red, sessile, fragrant flowers in small clusters preceding the deciduous leaves, and is indigenous to hilly and mountainous regions of Europe, extending to the Arctic Circle, and eastward to Siberia. The other two species are found in Southern Europe; *D. Laureola*, or *spurge laurel*, is also met with eastward to Asia Minor. This species has large evergreen leaves and yellowish-green flowers in axillary clusters, while the *spurge flax* (*D. Gnidium*) has narrow annual leaves and small white flowers in terminal, corymbose racemes. The bark is usually collected during the winter.

Description.—Mezereon-bark is in long bands about $\frac{1}{2}$ inch (12 Mm.) wide, $\frac{1}{4}$ th of an inch (1 Mm.) thick, either folded and tied together in bundles or rolled up into flat disks with the inner surface outward. The outer surface varies in color from pale-yellowish or brownish to brown-yellow, with a coppery lustre, and is marked with numerous minute blackish warts and transversely elongated leaf-scars, in the axils of which is found a cluster of blackish spots. Older bark shows some transverse fissures. The corky layer is easily separated from the pale-greenish outer bark, and with this from the bast-layer. The inner surface is whitish, of a silky lustre, and from loosened bast-fibres has a hairy appearance. The bark tears somewhat irregularly in a longitudinal direction, but with difficulty transversely. The fine and tough bast-fibres are in tangential rows and alternate with layers of parenchyma, this tissue being radially striate by narrow one-rowed medullary rays. The dried bark is inodorous and has a persistently acrid and burning taste.

FIG. 184.

Mezereon-bark: transverse section, magnified.

The bark of the spurge flax is of a darker brown color, and has numerous spirally arranged leaf-scars; that of the spurge laurel is more of a gray or brown-gray color, not prominently marked with leaf-scars, and has a greenish bast; both agree with mezereon-bark in acridity. The root-bark of the three species is regarded as the strongest, but the stem-bark is most generally met with.

Constituents.—Landerer observed (1836) that mezereon-bark contains a neutral acrid principle which volatilizes with the vapors of water; a similar observation was made by Squire (1842) with mezereon-root, and by Vauquelin (1808) with the distillate from water which had been used for washing the resin. The acrimony is, however, mainly due to a soft resin or oil, which, according to C. G. Gmelin (1822), is not precipitated by lead acetate from its alcoholic solution. This acrid principle deserves further investigation. Vauquelin (1808) discovered *daphnin* in the bark of spurge flax, and the same principle was isolated by Gmelin and Bär (1822) from mezereon-bark. Rochleder (1864) obtained it from the aqueous decoction of the alcoholic extract, after precipitating with sugar of lead, by precipitating it with subacetate of lead, decomposing with hydrogen sulphide, washing with ether, and crystallizing from water. It has a persistently bitter, not acrid, taste, and an acid reaction, dissolves readily in hot water and alcohol, is insoluble in ether, yields with alkalies yellow solutions, and colors ferric chloride blue.

Zwenger (1860) ascertained it to be a glucoside of the composition $C_{31}H_{34}O_{10} \cdot 4H_2O$, yielding *daphnetin*, $C_{19}H_{14}O_6$, which has a coumarin-like odor. On the dry distillation of the alcoholic extract *umbelliferon* is obtained.

Pharmaceutical Uses.—The comminution of the bark requires some precaution to avoid the injurious effects of the dust. The bark may be readily cut into small pieces, and should then be moistened with a little water, which should also be added on bruising the bark in a mortar.

Off. Prep.—Decoct. sarsaparillæ (sarsæ) comp., *U. S.*, *Br.*; Extr. mezerei æthereum, *Br.*; Extr. mezerei, Extr. mezerei fluid., Extr. sarsaparillæ compos. fluid., *U. S.*

Allied Drug.—FRUCTUS (GRANA) MEZEREI, S. GNIDI, S. COCCOGNIDI. —Mezereon-fruit, *E.*; Grains de garou, *Fr.*; Kellerhalskörner, *G.*—The berry-like fruit of the above species is in the fresh state red or of the spurge laurel blackish, globular-ovate or oval, about $\frac{1}{8}$ inch (5 Mm.) thick; after drying, brown or black, wrinkled; contains a black glossy seed, is inodorous, and has a strongly acrid and burning taste. Besides gum, vegetable acids, protein compounds, and other medicinally unimportant principles, Casselmann obtained from the fruit 31 per cent. of drying oil, 0.22 per cent. of acrid resin, and 0.38 per cent. of *coccognin*, which differs from daphnin in having a neutral reaction, in being very sparingly soluble in hot water, and in not being a glucoside; when heated it melts, and sublimes apparently unchanged, giving off a coumarin-like odor.

Physiological Action.—Ancient and modern authorities agree in describing various diseases which mezereon is fitted to cure. They all imply the possession by the medicine of acrid qualities; thus we learn that it irritated the fauces, and was capable of reddening, and even of blistering, the skin—that it was used as a gargle in sore throat and as an emetic, purgative, cholagogue, emmenagogue, and sudorific. Experiments on animals have proved it to be a violent irritant of the gastro-intestinal mucous membrane, and observations upon man lead to the same conclusion. In some of the latter there was narcotism or convulsion, and in one at least acrid and blood-red urine. Death has sometimes ensued. When the bark is chewed it in a little while excites a burning heat in the mouth, which lasts for many hours. In medicinal doses the decoction causes saliva-

tion and increased cutaneous and mucous secretions, which are said to acquire a peculiar odor. Excessive doses give rise to symptoms of gastro-intestinal irritation, with violent pain and sometimes very severe urinary irritation. When the bark is fresh or has been soaked in water or in vinegar, it reddens the skin, and at length occasions vesicles, followed by moist and painful ulcers which are difficult to heal. A case is recorded of a girl upon whose cheek the fresh juice of mezereon had been rubbed. Extreme swelling, pain, and a vesicular eruption were followed by fever and internal disorders, which are said, after the lapse of nine months, to have ended fatally.

We have elsewhere furnished illustrations of the narcotico-acrid action of mezereon-berries and of their use in medicine (*Therapeutics*, 4th ed., i. 407). Not long ago (1882) a case of poisoning by them occurred in England. A girl two and a half years old, having eaten a number of the berries, vomited, became dull and stupid, and then unconscious. The eyes were wide open, the pupils dilated, the face blue, the pulse and breathing very faint and slow. The lips and inside of the mouth looked swollen and as if burnt. After the evacuation of a large number of mezereon-seeds from the bowels recovery took place (Shaw, *Brit. Med. Jour.* and *Phila. Med. Times*, xiii. 101).

Medical Uses.—At one time mezereon was much in vogue as a remedy for *syphilis*, and to this day it is an ingredient of the compound decoction of sarsaparilla. But the evidence in its favor is not adapted to convince. In chronic non-syphilitic *cutaneous diseases* its reputation was equally ill-founded. In *chronic rheumatism* it seems to have been more useful, but here also its real value in a complex system of treatment is difficult to determine. It is seldom used alone, except as a *local irritant* in the form of the recent or moistened bark above referred to. In this respect it may more or less take the place of cantharides. It has been applied to improve the condition of foul or indolent *ulcers* and to maintain the discharge from *issues* and *setons*. For these purposes mezereon ointment is convenient. To excite vesication the bark, prepared as already described and bound firmly to the skin with a roller, should be freshly applied twice every day until vesication begins. Mezereon ointment may be used to prolong and renew the suppuration originally produced by cantharides.

When poisoning by mezereon occurs the stomach should be evacuated by lukewarm albuminous or mucilaginous liquids. Milk and fatty oils may also be administered.

MICA PANIS, Br.—BREAD-CRUMB.

Mie du pain, Fr.; *Brodkrumen*, G.

The soft part of bread made with wheat flour.

It is employed as an excipient in the preparation of certain pills, like those of corrosive sublimate, etc., and externally for emollient poultices. It is a constituent of *Cutiplasma carbonis*.

Medical Uses.—It may be presumed that this article was made officinal in order that only wheaten bread should be used. But in the only article for which it is directed, charcoal poultice, any other form of bread would answer equally well. In this country Indian corn meal is generally employed.

MISTURÆ VEL MIXTURÆ.

Mixturas, E.; *Potions, Mixtures*, Fr.; *Mixturen*, G.

Liquid medicines which contain insoluble substances in suspension, or which are composed of two or more liquids, with or without the addition of saline or other material, are termed "mixtures," and in its more limited application the term is restricted to mixtures intended for internal use. They are most frequently prepared extemporaneously and upon the prescriptions of physicians, since even among the officinal ones but few possess sufficient stability to permit them to be kept on hand for a longer period than a few days. Insoluble substances, when light and readily diffusible in water, do not generally require the addition of gum-arabic or other mucilaginous body to ensure their uniform suspension and the equalization of the dose; such an addition is desirable in all cases where the insoluble bodies are much heavier than water. However, some judicious restrictions are necessary, lest the insoluble compound form a compact deposit which cannot be readily suspended again by agitation. This difficulty may be avoided by reducing the gum to a very small proportion, and increasing the suspending power of the vehicle

by the addition of sugar or glycerin. When fats, volatile oils, or resinous substances are to be given in watery liquids, gum or the yolk of egg is requisite as a medium for uniform, and within certain limits permanent, suspension; such mixtures are opaque, and are called EMULSIONES (Emulsion, *E., Fr., G.*). Certain drugs, like the gum-resins and some seeds, naturally contain a principle (gum, emulsin, etc.) which is capable of keeping the oil or resin suspended in water, and when triturated with water yield emulsions; in all cases the drug should be rubbed or beaten into a uniform pasty mass, if necessary, with small quantities of water, the trituration being afterward continued with the gradual addition of water, after which the emulsion may be strained. Unglazed wedgewood or porcelain mortars having a rather flat bottom are very serviceable for this purpose. Under no circumstances should powdered gum-resins be employed, unless they have been powdered and sifted in cold weather, without having been previously dried by heat.

Fixed oils, to be emulsified, require as a rule one-half their weight of powdered gum-arabic, and the mixture may then be diluted with water to eight or ten times the quantity of oil employed. We have been informed by Mr. Boring that the employment of the infusion or syrup of wild cherry materially facilitates the perfect suspension of oils; infusion of malt, saponin-like bodies, and the soluble proteids more or less possess the same property. To prepare emulsions the powdered gum is triturated with not over one and a half times its weight of water; the oil is gradually added, each portion being completely emulsified before more is added, or the oil and gum are well mixed together; 1½ parts of water for 1 of gum are added at once and well triturated; when uniform, the remaining water may be incorporated. Dilg (1878) succeeded in making permanent emulsions by using gum-arabic equal to one-eighth the weight of the oil; the powdered gum, 1 part, is at once made into a thin mucilage with 4 parts of water; the oil is then mixed with it gradually, and when these are well combined 4 parts of water are added in small portions and with constant trituration, after which the mixture will bear copious dilution with water. If properly made, the oil will not separate, and if, after several days, a cream-like layer should rise to the surface, it may be readily incorporated with the aqueous liquid by agitation. For the proper emulsion of solid fats, and if not inadmissible also of camphor and resins, the addition of almond or similar fixed oil is advisable, but not indispensable. A yolk will readily emulsionize an ounce of fixed oil and facilitate the suspension of resins and volatile oils; the latter require a larger amount of gum than the fats, unless the process of J. W. Forbes (1872) be followed, who directs for 1 ounce of volatile oil, ether, or chloroform only 20 grains of gum-arabic. The liquid to be emulsionized is first introduced into a dry vial, and then the gum; the two are well mixed by agitation; ¼ ounce of water is added and thoroughly incorporated by agitation, after which the mixture is diluted with the remaining water or mucilage. On standing, a denser emulsion separates like cream, which is again readily mixed on slight agitation. In applying this process to fixed oils, E. Gregory (1876) found it necessary to increase the powdered acacia to three-eighths the weight of the oil.

EMULSIO OLEOSA of European pharmacy is prepared with 2 parts of expressed oil of almonds, 1 part of powdered acacia, and 17 parts of water.

The term SATURATIONS is applied in Europe to effervescing draughts made from lemon-juice, vinegar, tartaric or citric acid, to which is added a sufficient quantity of a carbonate to afford a nearly neutral salt, the solution remaining charged with as much carbonic acid gas as it will retain without being filtered. The weight of carbonates required for the neutralization of a given weight of acid will be seen from the following table:

100 parts of—	Potass. carb.	Potass. bicarb.	Sod. carb. exsicc.	Sod. carb. crystal.	Sod. bicarb.	Ammon. carb.	Magnes. carb.
Acidum citricum require.....	98	145	75	200	120	84	65
Limonis succus "	7	10	5	14	8.5	6	4.6
Acidum tartaricum "	92	133	70	190	112	78	60
Acetum (4.5 per ct. ac.) require.....	5	7.5	3.9	10.5	6.3	4.3	3.4

Mixtures are usually taken by the teaspoonful or tablespoonful; occasionally they are made of such a strength that they require to be taken by drops, and are then often distinguished as GUTTÆ (Drops, *E.*; Gouttes, *Fr.*; Tropfen, *G.*). If intended to be taken at once or in a few divided doses, the mixture is designated as HAUSTUS s. POTIO (Draught, *E.*; Tisane, Potion, *Fr.*; Tränkehen, *G.*). JULAPIUM (Julep, *E., Fr., G.*) is a sweet mixture rendered aromatic by the addition of volatile oil or medicated water, and occasionally colored by the use of a fruit syrup or a little cochineal, etc. A sweet mix-

ture prepared so as to have a thick syrupy consistence is still occasionally distinguished as *LINCTUS* (*vel* Looch, Lohoch, Eelegma).

It should be remembered that lemon-juice varies in strength, the above quantities being sufficient when containing from 7 to 7.5 per cent. of citric acid. The figures under Potass. carb. relate to the anhydrous pure salt. As a rule, a slight excess of acid is used in these extemporaneous preparations, which thereby become more agreeable to the taste.

MISTURA AMMONIACI, *U. S.*, *Br.*—AMMONIAC MIXTURE.

Emulsio ammoniaci, Lac ammoniaci.—*Ammoniacum mixture, Milk of ammoniac*, *E.*; *Emulsion (Mixture) de gomme ammoniacque, Lait ammoniacal*, *Fr.*; *Ammoniak-Emulsion*, *G.*

Preparation.—Ammoniac 4 parts (164 grains); Water 100 parts (4100 grains or 9 fluidounces). Rub the ammoniac with the water, gradually added, until they are thoroughly mixed, and strain.—*U. S.*

For 1 part of ammoniac the water ordered is 25 parts *U. S.*, 32 parts *Br.*; or for 1 fluidounce of water (wine measure) 18.22 grains *U. S.*, and (Imperial measure) 13.7 grains *Br.*, of ammoniac.

Medical Uses.—Mixture of ammoniac is employed chiefly in the treatment of chronic bronchitis and bronchorrhœa. The dose is 1 or 2 tablespoonfuls (Gm. 16–32).

MISTURA AMYGDALÆ, *U. S.*, *Br.*—ALMOND MIXTURE.

Emulsio amygdalæ, s. amygdalarum; Emulsio simplex.—*Milk of almonds*, *E.*; *Emulsion simple, Lait d'amandes*, *Fr.*; *Mandelemulsion, Mandelmilch*, *G.*

Preparation.—Sweet Almond 6 parts (246 grains); Acacia, in fine powder, 1 part (41 grains); Sugar 3 parts (123 grains); Distilled Water 100 parts (4100 grains or 9 fluidounces). Having blanched the almond, add the acacia and sugar, and beat them in a mortar until they are thoroughly mixed; then rub the mixture with the distilled water, gradually added, and strain.—*U. S.*

Take of compound powder of almonds 2½ ounces; distilled water 1 pint. Rub the powder with a little of the water into a thin paste, then add the remainder of the water, and strain through muslin.—*Br.*

The presence of gum-arabic in both preparations does not increase the stability of either or the amount of oil suspended. Without using gum, 10 parts of sweet almonds are ordered for 100 parts (*P. G.*), 200 parts (*F. Cod.*), of water. European physicians sometimes prescribe the following *compound emulsion of almonds*:

EMULSIO AMYGDALARUM COMPOSITA. Take of sweet almonds 4 parts; hyoscyamus-seed 1 part; diluted bitter-almond water 64 parts. Make an emulsion, and add of white sugar 6 parts, calcined magnesia 1 part.—*P. G.* 1872.

LOOCH ALBUM.—White linctus, *E.*; Looch blanc, *Fr.*—30 parts of sweet and 2 parts of bitter almonds are blanched, triturated with 20 parts of sugar and 120 parts of water, and the emulsion strained and gradually added, with continued trituration, to a mixture of 10 parts of sugar and 0.5 part of powdered tragacanth. Finally, add 10 parts of orange-flower water. The finished preparation weighs 150 parts.—*F. Cod.*

Medical Uses.—Almond mixture is an excellent demulcent in *acute laryngeal* and *bronchial* inflammations, *dysentery*, and irritations of the *urinary passages*. It should be administered freely. The white linctus of the French Codex is an excellent palliative of pharyngeal, laryngeal, and bronchial irritation.

MISTURA ASAFÆTIDÆ, *U. S.*—ASAFÆTIDA MIXTURE.

Lac asafœtidæ.—*Milk of asafœtida*, *E.*; *Mixture (Lait) d'asafœtida*, *Fr.*; *Asafœtida-Emulsion, Stinkasantmilch*, *G.*

Preparation.—Asafetida 4 parts (164 grains); Water 100 parts (4100 grains or 9 fluidounces). Rub the asafetida with the water, gradually added, until they are thoroughly mixed.—*U. S.*

The asafetida has been increased from 15 to 18.22 grains per fluidounce.

A *syrup of asafetida*, of the same strength by volume as the mixture, may be prepared by triturating 150 grains of selected tears with small quantities of water, decanting the concentrated emulsion until 4 fluidounces are obtained, in which 6 troyounces of sugar are dissolved by agitation. While at first milk-white, it acquires after exposure a pinkish color; the resin, which partially separates on standing, is easily incorporated by

agitation. If desired, the asafetida odor may be covered by the addition of a little oil of bitter almonds, or, as suggested by J. J. Rambo (1871), by substituting infusion of wild-cherry bark for the water, which changes the white to a brownish color.

A *wine of asafetida* was recommended by H. N. Rittenhouse (1855) to be made by triturating $\frac{1}{2}$ troyounce of the gum-resin with sufficient white wine to obtain 2 fluidounces, 1 drachm of which, mixed with $5\frac{1}{2}$ fluidrachms of water, represents approximately the official mixture.

Medical Uses.—Asafetida mixture is the most prompt and decided in its action of all the forms of administering asafetida by the mouth. It is frequently given as an enema, but for the latter purpose a mixture of an ounce of tincture of asafetida with half a pint of water is more convenient and efficient. The *dose* of mixture of asafetida is 1 or 2 tablespoonfuls (Gm. 16–32).

MISTURA CHLOROFORMI, U. S.—CHLOROFORM MIXTURE.

Emulsio chloroformi.—*Emulsion de chloroforme*, Fr.; *Chloroform-Emulsion*, G.

Preparation.—Purified Chloroform 8 parts (320 grains); Camphor 2 parts (80 grains); Fresh Yolk of Egg 10 parts (400 grains); Water 80 parts (3200 grains or 7 fluidounces); to make 100 parts (4000 grains or about 8 fluidounces). Rub the yolk of egg in a mortar, first by itself, then with the camphor previously dissolved in the chloroform, and lastly with the water, gradually added, so as to make a uniform mixture.—*U. S.*

Medical Uses.—This mixture forms a stable preparation which may sometimes be convenient for the administration of chloroform in cases of *gastralgia*, *flatulent*, *biliary*, *renal*, and *uterine colic*, and in *nervous* or *hysterical* paroxysms. The *dose* is 1 or 2 tablespoonfuls (Gm. 16–32).

MISTURA CREASOTI, Br.—CREASOTE MIXTURE.

Mixture de créosote, Fr.; *Kreosot-Mixtur*, G.

Preparation.—Take of Creasote, Glacial Acetic Acid, each 15 minims; Spirit of Juniper $\frac{1}{2}$ fluidrachm; Syrup 1 fluidounce; Distilled Water 15 fluidounces. Mix the creasote with the acetic acid, gradually add the water, and lastly the syrup and spirit of juniper.—*Br.*

Medical Uses.—Creasote mixture, it is stated, is intended to allay *vomiting*, but the bulk of its dose and the spirit of juniper and syrup contained in it render it peculiarly unfit to relieve the cases of vomiting in which creasote is most useful. The purpose of the glacial acetic acid in this mixture is not evident. The *dose* is stated to be from 1 to 2 ounces (Gm. 32–64).

MISTURA CRETÆ, U. S., Br.—CHALK MIXTURE.

Mixture avec la craie, Fr.; *Kreidemixtur*, G.

Preparation.—Compound Chalk Powder 20 parts (400 grains); Cinnamon-Water 40 parts (800 grains or 14 fluidrachms); Water 40 parts (800 grains or 14 fluidrachms); to make 100 parts (2000 grains or about 4 fluidounces). Rub the powder with the cinnamon-water and water, gradually added until they are thoroughly mixed. This preparation should be freshly made when wanted for use.—*U. S.*

Take of prepared chalk $\frac{1}{4}$ ounce; gum-acacia, in powder, $\frac{1}{4}$ ounce; syrup $\frac{1}{2}$ fluidounce; cinnamon-water $7\frac{1}{2}$ fluidounces. Triturate the chalk and gum-acacia with the cinnamon-water, then add the syrup, and mix.—*Br.*

This mixture spoils readily during warm weather; the addition of a little glycerin or the substitution of glycerin for the sugar, as recommended by G. W. Kennedy (1872), would tend to preserve it for several days while in the hands of the patient, but it should be dispensed only freshly made.

Medical Uses.—Chalk mixture is one of the most convenient forms in which chalk can be administered in the *diarrheas* both of adults and children, especially when the discharges are yeasty or greenish and there is flatulent distension of the abdomen with sour eructations. If there is reason to suspect the presence of undigested food in the bowels, a dose of magnesia should first be given. For the watery diarrhœa which often precedes the attack of *epidemic cholera* there is no better medicine than this. In most cases laudanum should be added to the mixture or given along with it, and ordinarily its

efficiency is much increased by the addition of kino, krameria, or catechu. The dose is a tablespoonful (Gm. 16).

MISTURA FERRI AROMATICA, *Br.*—AROMATIC MIXTURE OF IRON.

Potion (Mixture) de fer aromatique, Fr.; Aromatische Eisenmixture, G.

Preparation.—Take of Pale Cinchona-Bark, in powder, 1 ounce; Calumba-Root, in coarse powder, $\frac{1}{2}$ ounce; Cloves, bruised, $\frac{1}{4}$ ounce; Fine Iron Wire $\frac{1}{2}$ ounce; Compound Tincture of Cardamoms 3 fluidounces; Tincture of Orange-Peel $\frac{1}{2}$ fluidounce; Peppermint-Water a sufficiency. Macerate the cinchona-bark, calumba-root, cloves, and iron with 12 fluidounces of the peppermint-water in a closed vessel for 3 days, agitating occasionally; then filter the liquid, adding as much peppermint-water to the filter as will make the product measure 12 $\frac{1}{2}$ fluidounces; to this add the tinctures, and preserve the mixture in a well-stopped bottle.—*Br.*

This has been introduced into the British from the old Dublin Pharmacopœia. During the maceration a portion of the iron is dissolved by the organic acids contained in the drugs.

Medical Uses.—This is a mixture of bitter tonics and aromatic stimulants with a modicum of iron. Many years ago it was appropriately described by Neligan, who said; “In consequence of its black color it is commonly known as *Heberden's ink*.” Notwithstanding its being an unchemical compound, it is a most excellent tonic; it is very generally used in Dublin in the various states of debility attended with anæmia. Dose, from 1 to 2 fluidounces (Gm. 32–64).

MISTURA FERRI COMPOSITA, *U. S., Br.*—COMPOUND IRON MIXTURE.

Griffith's mixture, E.; Mixture de Griffith, Fr.; Griffith's Eisenmixture, G.

Preparation.—Sulphate of Iron, in coarse powder, 6 parts (18 grains); Myrrh, in small pieces, 18 parts (54 grains); Sugar 18 parts (54 grains); Carbonate of Potassium 8 parts (24 grains); Spirit of Lavender 50 parts (150 grains or 190 minims); Rose-Water 900 parts (2700 grains or 5 fluidounces and 7 $\frac{1}{2}$ fluidrachms); to make 1000 parts (3000 grains or about 6 $\frac{1}{2}$ fluidounces). Rub the myrrh, sugar, and carbonate of potassium with the rose-water, gradually added, then with the spirit of lavender, and lastly with the sulphate of iron. Pour the mixture immediately into a bottle, which should be well stopped. This preparation should be freshly made when wanted for use.—*U. S.*

The manipulation directed by the British Pharmacopœia differs only in dissolving the ferrous sulphate in a small portion of the rose-water previous to adding it to the remaining mixture. The ingredients are sulphate of iron 25 grains; carbonate of potassium 30 grains; myrrh and refined sugar, each 60 grains; spirit of nutmeg 4 fluidrachms; and rose-water 9 $\frac{1}{2}$ fluidounces (Imperial).

The preparation of this mixture presents no difficulty if good tears of myrrh are selected and the directions are strictly followed. The reaction between the iron and potassium salts, resulting in the formation of ferrous carbonate and potassium sulphate, takes place in the myrrh emulsion, by which the insoluble ferrous carbonate is kept in suspension. Unless in full and well-corked bottles, the mixture, at first of a dirty-greenish color, is hardly protected against oxidation by the small quantity of sugar present, and should be freshly made when needed.

Medical Uses.—This preparation has special advantages over other ferruginous medicines in several chronic affections, and especially in *chlorotic anæmia*, *chronic bronchitis*, *albuminuria*, and certain chronic diseases of the skin (eczema, psoriasis). These disorders have in common a deteriorated condition of the blood and a debility of the nervous system, which the iron of the mixture is adapted to correct, and several among them present in addition a relaxed state of the secretory organs, which the myrrh and the sulphuric acid tend to counteract. The first-named two are those which usually exhibit the most favorable results of its use. The mixture was originally called *antihæctic* from the utility it manifested in hectic conditions of pulmonary disease—not those, however, as is sometimes erroneously supposed, which belong to tubercular consumption, but those of chronic bronchitis attended with purulent expectoration, and usually associated with dilatation of the bronchia. The dose is from $\frac{1}{2}$ ounce to 1 $\frac{1}{2}$ ounces (Gm. 16–40) two or three times a day.

MISTURA FERRI ET AMMONII ACETATIS, U. S.—MIXTURE OF ACETATE OF IRON AND AMMONIUM.

Mistura martiata Basham.—Basham's mixture, E.; *Potion (Mixture) de Basham*, Fr.; *Basham's Eisenmixture*, G.

Preparation.—Tincture of Chloride of Iron 2 parts (100 grains or 93 minims); Diluted Acetic Acid 3 parts (150 grains or 160 minims); Solution of Acetate of Ammonium 20 parts (1000 grains or 2½ fluidounces); Elixir of Orange 10 parts (500 grains or 7 fluidrachms); Syrup 15 parts (750 grains or 70 fluidrachms); Water 50 parts (2500 grains or 5½ fluidounces): to make 100 parts (5000 grains, or nearly 11½ oz. av., or 9½ fluidounces). To the solution of acetate of ammonium, previously mixed with the diluted acetic acid, add the tincture of chloride of iron, and then the elixir of orange, syrup, and water, and mix the whole thoroughly.—U. S.

Ferrie chloride and ammonium acetate mutually decompose each other, forming ferrie acetate and ammonium chloride, only about 10 per cent. of ammonium acetate remaining undecomposed. "Mistura ferri acetatis composita" would therefore seem to be a more appropriate title for this new official preparation.

Uses.—This preparation has long been used in the treatment of various forms of *albuminuria*, but chiefly in that which attends tubular nephritis. Its recommendations are its agreeable appearance, its not unpleasant taste, its acceptability by the stomach, and its diuretic action derived from its acid and ammonia. *Dose*, from ½ fluidounce to 1 fluidounce (Gm. 15–30).

MISTURA GENTIANÆ, Br. 1867.—GENTIAN MIXTURE.

Potion de gentiane, Fr.; *Enzianmixture*, G.

Preparation.—Take of Gentian-Root, sliced, ½ ounce; Bitter Orange-Peel, cut small, Coriander-Fruit, bruised, each 30 grains; Proof Spirit 2 fluidounces; Distilled Water 8 fluidounces. Macerate the gentian, orange-peel, and coriander in the proof spirit for 2 hours; then add the water, macerate again for 2 hours, and strain through calico.

This is nearly identical with the compound infusion of gentian, U. S. 1870 (see page 819). *Dose*, from ½ fluidounce to 1 fluidounce (Gm. 15–30).

MISTURA GLYCYRRHIZÆ COMPOSITA, U. S.—COMPOUND MIXTURE OF LIQUORICE.

Brown mixture, E.; *Mixture de réglisse*, Fr.; *Lakritzen-Mixture*, G.

Preparation.—Pure Extract of Glycyrrhiza 3 parts (300 grains); Sugar, in coarse powder, 3 parts (300 grains); Acacia, in fine powder, 3 parts (300 grains); Camphorated Tincture of Opium 12 parts (1200 grains or 2¾ fluidounces); Wine of Antimony 6 parts (600 grains or 11 fluidrachms); Spirit of Nitrous Ether 3 parts (300 grains or 6½ fluidrachms); Water 70 parts (7000 grains = 16 oz. av. or 15¾ fluidounces): to make 100 parts (10,000 grains = 22½ oz. av. or about 21½ fluidounces). Rub the extract of glycyrrhiza, sugar, and acacia with the water, gradually added; then add the other ingredients, and mix the whole thoroughly.—U. S.

This formula is nearly identical with that of 1870; a slight increase in spirit of nitrous ether has been made, and the commercial powdered extract of liquorice has been replaced by the extract prepared by cold infusion from the root. The mixture has now a somewhat lighter color than formerly, and is not turbid and unsightly in appearance from the presence of the insoluble matters contained in powdered extract of liquorice. An equally efficient mixture is obtained by using *purified* extract of liquorice (see page 637).

Medical Uses.—Compound liquorice mixture, or *brown mixture*, as it is frequently called, is an agreeable and efficient remedy in the early stages of *acute bronchitis* and catarrhal *laryngitis*. It hastens and promotes expectoration, chiefly by reducing the febrile tension of the vascular system. The average *dose* for an adult is a tablespoonful (Gm. 16).

MISTURA GUAIACI, Br.—GUAIAECUM MIXTURE.

Emulsio resinæ guaiaci.—*Emulsion de résine de guaiac*, *Lait de guaiac*, Fr.; *Guajak-Emulsion*, G.

Preparation.—Take of Guaiacum Resin, in powder, Refined Sugar, each half an

ounce; Gum-Acacia, powdered, $\frac{1}{4}$ ounce; Cinnamon-Water 1 pint. Triturate the guaiacum with the sugar and the gum, adding gradually the cinnamon-water.—*Br.*

This is a partial emulsion of guaiac resin, which, on exposure, soon changes in color (see page 750).

Medical Uses.—Although unpleasant to the taste, it is perhaps less repulsive than the tinctures of guaiac. Very probably also the guaiacum in it, being thoroughly divided by sugar and gum, is more readily acted upon and absorbed by the stomach than the solid mass precipitated from a tincture would be. *Dose*, from 1 to 4 tablespoonfuls (Gm. 16–64) several times a day.

MISTURA MAGNESIÆ ET ASAFÆTIDÆ, U. S.—MIXTURE OF MAGNESIA AND ASAFETIDA.

Mistura carminativa Dewees.—*Dewees' carminative*, E.; *Mixture carminative de Dewees*, Fr.; *Dewees' Carminativ*, G.

Preparation.—Carbonate of Magnesium 5 parts (350 grains); Tincture of Asafetida 7 parts (490 grains or $8\frac{1}{2}$ fluidrachms); Tincture of Opium 1 part (70 grains or 75 minims); Sugar 10 parts (700 grains or $1\frac{1}{2}$ oz. av.); Distilled Water a sufficient quantity; to make 100 parts (7000 grains). Rub the carbonate of magnesium and sugar in a mortar with the tincture of asafetida and tincture of opium. Then gradually add enough distilled water to make the mixture weigh 100 parts (7000 grains = 16 oz. av. or about 15 fluidounces).—*U. S.*

Medical Uses.—It is to be regretted that this mixture was made official. An intelligent physician would desire to vary the proportions of its several constituents, and especially of its narcotic ingredient, for almost every case of infantile colic under his care. Such mixtures do not tend to promote rational medicine. It will be observed that the laudanum in this mixture forms one-hundredth of the whole. The average *dose* is about 20 drops (Gm. 1.25).

MISTURA POTASSII CITRATIS, U. S.—MIXTURE OF CITRATE OF POTASSIUM.

Mistura neutralis.—*Neutral mixture*, E.; *Potion gazeuse (effervescente)*, Fr.

Preparation.—Fresh Lemon-Juice, strained, 100 parts (1 fluidounce); Bicarbonate of Potassium about 10 parts (45 grains) or a sufficient quantity. Add the bicarbonate of potassium gradually to the lemon-juice until it is neutralized.

In composition this mixture is identical with LIQUOR POTASSII CITRATIS (page 921), but, being prepared with fresh lemon-juice, is aromatic and more agreeable. The juice should be strained before the bicarbonate is added, to avoid the expulsion of the carbonic acid gas by subsequent straining. Owing to the variable acid strength of lemon-juice, the amount of potassium bicarbonate necessary for neutralization may vary considerably; it is usually between 45 and 50 grains for each fluidounce, but may be 60 grains or more. Since as much carbonic acid gas as possible is to be retained in the mixture, litmus-paper is useless for determining the neutralization. A pleasantly acidulous mixture well charged with carbonic acid gas is obtained by first using for each fluidounce of juice 40 grains of the bicarbonate, and after this has been dissolved introducing from 10 to 15 grains of the same salt in large crystals; as soon as, after moderate stirring, carbonic acid gas is seen to arise from the crystals slowly and in distinct bubbles, the liquid should be poured off from the crystals and dispensed. A few drops of the solution heated to boiling should show a faintly acid or neutral, but not an alkaline, reaction to test-paper.

Medical Uses.—Neutral mixture is diaphoretic and diuretic. It is very generally employed as a *febrifuge*, either alone or with the addition of antimonial wine, of spirit of nitrous ether, of morphine, or of all united. It should be administered diluted with water, or, where no contraindication exists, with lemonade. The *dose* is a tablespoonful (Gm. 16).

MISTURA RHEI ET SODÆ, U. S.—MIXTURE OF RHUBARB AND SODA.

Potion à la rhubarbe alcaline, Fr.; *Alkalische Rhubarbermixtur*, G.

Preparation.—Bicarbonate of Sodium 30 parts (60 grains); Fluid Extract of Rhubarb 30 parts (60 grains); Spirit of Peppermint 30 parts (60 grains or 77 minims);

Water a sufficient quantity (about 1820 grains or 4 fluidounces): to make 1000 parts (2000 grains or 4½ oz. av.). Dissolve the bicarbonate of sodium in 500 parts (1000 grains or 2½ fluidounces) of water. Add the fluid extract of rhubarb and the spirit of peppermint, and lastly enough water to make the mixture weigh 1000 parts.—*U. S.*

The mixture has a deep brown-red color.

Medical Uses.—Like the mixture of magnesia and asafetida, this preparation is much more appropriate for magistral than official for prescription. The Pharmacopœia already possesses the aromatic syrup of rhubarb, which is purgative and carminative, and to it bicarbonate of sodium is commonly added when required. The *dose* of this mixture is variously stated at from ½ drachm (*U. S. D.*) to 3 ounces (*Ede's Handbook*). For infantile dyspeptic *colic* and *diarrhœa* about ½ fluidrachm (Gm. 2) may be given, and repeated, if necessary, at hourly intervals.

MISTURA SCAMMONII, *Br.*—SCAMMONY MIXTURE.

Emulsio purgans cum scammonia, Lac scammonii.—*Emulsion purgative avec la scammonée, Mixture de scammonée, Fr. ; Scammonium-Emulsion, G.*

Preparation.—Take of Scammony, in powder, 6 grains; Milk 2 fluidounces. Triturate the resin of scammony with a little of the milk, and continue the trituration, gradually adding the remainder of the milk, until a uniform emulsion is obtained.—*Br.*

Scammony resin is readily emulsionized with milk. The French Codex directs 1 part of the resin to be first triturated with 15 parts of sugar, afterward with 120 parts of milk, and the emulsion to be flavored with five parts of cherry-laurel water.

Medical Uses.—Scammony forms with unskimmed milk a fine uniform emulsion which perfectly suspends the drug and conceals its acrid and nauseous taste. The mixture is intended to be a *dose* for an adult; for a child of five years one-third of the quantity will suffice.

MISTURA SENNÆ COMPOSITA, *Br.*

(See Compound Mixture of Senna, under INFUSUM SENNÆ, page 822.)

MISTURA SPIRITUS VINI GALlici, *Br.*

Mixture of spirit of French wine, Brandy mixture, E. ; Mixture de cognac, Fr. ; Branntwein-Mixtur, G.

Preparation.—Take of Spirit of French Wine, Cinnamon-Water, each 4 fluidounces; the Yolks of 2 Eggs; Refined Sugar ½ an ounce. Rub the yolks and sugar together, then add the cinnamon-water and spirit.—*Br.*

In our opinion this preparation scarcely deserves a place in a pharmacopœia.

Medical Uses.—As a nutritious and stimulant draught this preparation is often useful in *typhoid states* of fever and in exhaustion from nervous excitement, hæmorrhage, and other conditions which do not contraindicate the use of alcohol. "Eggnog" made with milk is much more efficient than this preparation.

MITCHELLA.—MITCHELLA.

Partridgeberry, Checkerberry, Squaw-vine, Winter-clover, E.

Mitchella repens, Linné.

Nat. Ord.—Rubiaceæ, Cinchoneæ.

Description.—This pretty North American evergreen, which is found in woods, has a creeping and branching stem 10 to 12 inches (25–30 Cm.) long, and opposite petiolate, roundish-ovate, entire leaves, which are about ½ inch (12 Mm.) long, and often marked with white lines. The flowers are in pairs, often diœcious, have a white or pale-purplish funnel-shaped corolla, and four exserted or included stamens, and produce a rather dry berry-like scarlet-red fruit, which is composed of two united ovaries and contains four bony nutlets. The flowers are fragrant; the leaves are inodorous, somewhat astringent, and bitter.

We have no knowledge of any analysis of this plant.

Medical Action and Uses.—The virtues of this plant are exceedingly indefinite, for it is reputed to be diuretic, tonic, and astringent, and capable of facilitating childbirth

if taken for several weeks before the close of pregnancy. It very probably may be useful in chronic disorders of the urinary passages when given in decoction.

MONARDA.—HORSEMINT.

American horsemint, E.; *Menthe de cheval*, Fr.; *Pferdeminze*, G.

The leaves and tops of *Monarda punctata*, Linné. Bentley and Trimen, *Med. Plants*, 208.

Nat. Ord.—Labiatae, Monardeae.

Origin.—Horsemint is a perennial herb 1 to 2 feet (30–60 Cm.) high, which is indigenous to the United States, where it grows in dry sandy fields from New York westward to Illinois, and southward to near the Gulf of Mexico. It flowers in the latter part of summer until September, and should be collected with the flowering-tops.

Description.—The leaves are about 2 inches (5 Cm.) long, lanceolate, somewhat toothed, acute, narrowed at the base into a petiole, smooth above, and glandular dotted beneath. The whorls of cymules are about ten-flowered, situated in the axils of the upper leaves, and surrounded by about eight leafy, sessile, and entire bracts, which are pale-yellow and purple in color. The tubular, downy calyx is divided into five short and rigid teeth. The corolla is prominent, yellowish, with the large arched upper lip spotted with purple, and a small, three-lobed, somewhat crisped lower lip. The two slender exerted stamens are inserted in the throat above the narrow corolla-tube. Horsemint has a strong aromatic odor and a warm, pungent, somewhat bitterish taste.

FIG. 185.
Flower of *Monarda punctata*, Linné.

Other Species of Monarda.—*M. DIDYMA*, Linné, or *Oswego tea*, is found in the Alleghanies and northward to Canada and Wisconsin. It has the larger bracts and floral leaves tinged with red, and showy bright-red corollas, with the stamens exerted beyond the narrow upper lip.

M. FISTULOSA, Linné, or *wild bergamot*, has the larger bracts and floral leaves of a grayish tint, and whitish or pale-purplish flowers with exerted stamens; it grows in woodlands from New England to Wisconsin southward.

Substitutions.—In some counties of Pennsylvania *Pycnanthemum incanum*, Michx., or *wild basil*, is known and popularly used as horsemint; the plant is downy to hoary, has acute, ovate, or oblong leaves, the upper ones whitened, and the flowers in dense heads with narrow linear bracts and awned calyx-lobes. In Great Britain, *Mentha sylvestris*, Linné, is known as horsemint.

Constituents.—The important constituent is the volatile oil, which is contained in the leaves and flowers; nothing is known about the other principles, among which are doubtless those commonly met with in herbaceous plants.

OLEUM MONARDE, U. S. 1870.—Oil of horsemint, E.; *Essence de menthe de cheval*, Fr.; *Pferdeminzöl*, G.—This volatile oil is obtained in the United States from fresh horsemint by distillation with water or steam. It is yellowish or usually of a reddish or brownish-red color, lighter than water, readily soluble in alcohol, crystallizing below 5° C. (39° F.), and of a peculiar fragrant odor and pungent taste. Boiled with nitro-prusside of copper, it becomes colorless, greenish, brown, and finally nearly black. Iodine dissolves quietly, turning the oil bright red, afterward blackish and pitchy. The elæopten is probably a hydrocarbon, but has not been examined. The stearopten is *thymol*, $C_{10}H_{14}O$, identical with that obtained from oil of thyme. (See **THYMOL**.)

Medical Uses.—Horsemint is regarded as being diaphoretic, diuretic, carminative, and emmenagogue, like most other plants of its class containing an acrid essential oil. It may be used in hot infusion to prevent the formation of *catarrhal*, *rheumatic*, and *diarrhæal* affections occasioned by cold. The infusion is usually made with half an ounce of the herb in a pint (Gm. 16 to Gm. 500) of hot water, and may be given in wine-glassful doses. The smallest drop of the oil of horsemint diffuses a pungent, aromatic, and persistent heat over the tongue and fauces; when applied to the skin it excites redness and heat, and, if the application is continued, pain and vesication also. It may be used for the same purposes as oil of peppermint, etc., but is more frequently employed with soap liniment or camphorated oil as an embrocation to relieve the pain of *muscular rheumatism*, *chronic articular rheumatism*, and *neuralgia*. It is also applied in liniments in local *paralysis*, *flatulent colic*, *cholera infantum*, and even in *low forms of fever*. For these purposes 1 part of the oil to 3 or 4 of the excipient may be prescribed. In neuralgia it may be

applied pure. Internally, the oil may be given in doses of 2 or 3 drops (Gm. 0.06–0.20), properly diluted with sweetened water.

MONESIA.—MONESIA-BARK.

The bark of *Chrysophyllum glycephalum*, *Casaretti*.

Nat. Ord.—Sapotaceæ.

Origin.—The tree yielding monesia-bark is indigenous to the forests of Brazil, and has alternate, coriaceous, and entire leaves. The berry-like fruits of several species of *Chrysophyllum* are edible, Ch. Cainito, *Linné*, being known as *star-apple*.

Description.—The bark is in flat or curved pieces $\frac{1}{2}$ to nearly $\frac{1}{4}$ inch (3 to 6 Mm.) thick, often 2 or 3 inches (5 or 7 Cm.) broad, externally marked with confluent ridges, forming large irregularly quadrangular or hexagonal meshes, which are covered with a thin, smooth, whitish tissue while the bark is young. The inner surface is cinnamon-colored and longitudinally striate, otherwise smooth. The bark is very hard, breaks with a granular fracture, and shows in the interior alternate layers of brown and pale-reddish tissue. It is inodorous and has a peculiar taste, which is at first sweet like liquorice, afterward bitterish, somewhat acrid and astringent.

Constituents.—Monesia-bark was examined by Derosne, Henry, and Payen (1840), who announced the presence of *glycyrrhizin*, *monesin*, which appears to be identical with saponin, *tannin*, red coloring matter resembling kinic red, trace of volatile oil, pectin. 3 per cent. of ash, etc. Heydenreich (1839) separated from the aqueous extract 52 per cent. of tannin and 36 per cent. of a sweet principle, which was not precipitated by sulphuric acid or lead acetate, and was not fermentable.

EXTRACTUM MONESIÆ, *Monesia*, comes from Brazil in irregular dark-brown friable angular pieces, destitute of any red hue. It is soluble in water, and has a sweet afterward astringent taste, followed by slight but persistent acidity.

Allied Trees.—*ACHRAS SAPOTA*, *Linné*, s. *Sapota Achras*, *Miller*. The tree is known in the West Indies and South America as *sapota*; it is 40 or 50 feet (12–15 M.) high, with large whitish flowers and globular-oval somewhat angular fruits, which are externally rust-brown and rough, internally whitish, and soft-pulpy, and contain several glossy black seeds. The tree contains a bitter milk-juice.

The bark has a bitter and strongly astringent taste, and is employed as a substitute for cinchona. Bernou (1882) found in it two resins, one of which is soluble in ether, 11.8 per cent. of tannin, and the alkaloid *sapotine*, which is soluble in alcohol, ether, and chloroform, and is precipitated from its salts by ammonia.

The fruit, after it has become fully ripe, has a quince-like flavor, and is known as *sapodilla plum*. The very bitter seeds possess diuretic and aperient properties.

MIMOSA ELENGI, *Linné*. The bark and root are used in India as a tonic and astringent; the flowers yield by distillation with water a very fragrant perfume; the fruit is sweet and edible; the seeds yield a fixed drying oil, and the timber is durable and heavy.

BASSIA LONGIFOLIA, *Linné*. The East Indian *eltopa tree* yields valuable timber, and from the flowers and fruits a nourishing jelly; the leaves and bark, like the fixed oil of the seed, are used in rheumatic and cutaneous diseases. A similar use is made of *fulva-butter*, a butyrateous fat prepared from the pale-brown glossy seeds of *Bassia butyracea*, *Roxburgh*.

Medical Action and Uses.—Internally and in small doses, as from 4 to 8 grains, monesia gives tone to the stomach and increases the appetite, but in doses of 20 or 30 grains it occasions gastric oppression and constipation. Upon recent sores it causes a burning and stinging pain of brief duration, lessening their secretions and promoting granulation and cicatrization. Monesin acts upon such sores as a more active irritant, inducing rapidly a plastic exudation.

The medicinal uses of monesia denote its possession of a stimulant as well as an astringent property. It has been found useful in atonic *dyspepsia*, in vomiting produced by atony rather than by active irritation of the stomach, and in all forms of *diarrhœa* unattended with fever. It has been employed with profit in chronic *bronchitis*, in various forms of hæmorrhage, especially *hæmoptysis* and *menorrhagia*, and locally by injection in *epistaxis*. In various ecchymoses depending upon *scurvy* its internal administration is said to have been advantageous. As a topical application it has been recommended in *ulcers* and *pseudo-membranous* exudations of the mouth and fauces and of many other parts, also in *leucorrhœa*, *gleet*, and *diarrhœa*, and especially in *fissures of the mouth and anus*. Although these virtues of monesia appear to have been demonstrated by clinical observation, the medicine seems to have been neglected and almost fallen into disuse.

The dose of monesia may be stated at from 3 to 20 grains (Gm. 0.15–1.30) or from 10

to 60 grains (0.60–4) a day. Monesin has been recommended in the dose of $\frac{1}{2}$ grain. For local applications the tincture diluted with from 10 to 20 parts of water has been used: also an ointment made with 1 part of the extract to 7 of lard, and a glycerole of similar proportions.

MORI SUCCUS, *Br.*—MULBERRY-JUICE.

Succus mororum.—*Suc de mûres*, Fr.; *Maulbeersaft*, G.

The juice of the ripe fruit of *Morus nigra*, *Linné*. Steph. and Church, *Med. Bot.*, plate 39; Bentley and Trimen, *Med. Plants*, 229.

Nat. Ord.—Urticaceæ, Artocarpeæ.

Origin.—The black like the white mulberry, *Morus alba*, *Linné*, is indigenous to the Levant; both are rather small trees, about 30 feet (9 M.) high, and are cultivated and partly naturalized in Europe, where the leaves of both, more generally of the white, are employed for feeding the silkworm. Both species are also occasionally seen in cultivation in the United States; *M. alba*, however, is alone naturalized. The mulberry is usually monœcious; the staminate flowers are in loose catkins, the pistillate flowers in short dense spikes; the latter flowers contain a two-celled ovary with two thread-like styles, one of the cells disappearing after fructification, while the four-lobed calyx becomes fleshy.

Description.—Through the coalescence of the fleshy calyces the pistillate spikes of the mulberry ripen into what appears to be a compound berry or drupe having some resemblance to the blackberry. The mulberry is of an oblong or ovate form, about 1 inch (25 Mm.) long, fleshy and juicy, purplish-black, each fruit crowned with the filiform styles. The fruit proper is a lenticular akene enclosed in the fleshy calyx. Mulberries contain a dark reddish-purple juice, and have scarcely any odor, but possess a very agreeable acidulous taste.

MORUS RUBRA, *Linné*, is common in rich woods in the United States from Western New England southward to Florida and westward to Dakota and New Mexico. It is usually about 20 feet (6 M.), but occasionally 60 feet (18 M.), high, and has a durable hard, yellowish wood. The fruit is dark-purple, 1 to 1½ inches (25–38 Mm.) long, and otherwise resembles the preceding.

Constituents.—From comparative experiments made in the laboratory of Fresenius (1857), it appears that mulberries contain more sugar than gooseberries, currants, strawberries, raspberries, blackberries, and huckleberries, while in the free acid they are about intermediate between wild and cultivated raspberries. The analytical results, as obtained by Van Hees, were as follows, calculated for 100 parts of the fruit: sugar 9.192, free acid (estimated as malic acid) 1.860, albuminous compounds 0.394, pectin, gum, and other organic compounds 2.031, ashes 0.566, and water 84.707 parts, the remaining 1.250 parts consisting of the akenes and other tissues, with the insoluble organic compounds and ash.

C. R. A. Wright and G. Patterson (1878) examined the juice expressed from mulberries not quite ripe, and obtained from the liter 26.83 Gm. of citric acid, 7.82 malic acid, 2.74 glucose, 23.37 other organic constituents, and 9.40 ash—a total of 70.16 Gm. of solids. This juice had slightly fermented, and contained a trace of volatile, probably acetic, acid.

Off. Prep.—*Syrupus mori*, *Br.*

Medical Uses.—Mulberries are refreshing to the taste like all subacid fruits, and slightly laxative. Their fresh juice, or a syrup prepared with it, is frequently employed in Europe for the same purposes to which in this country the juice and jelly of currants are applied—viz. in *inflammations* with *fever*, and especially in *sore throat*. The bark of the root of *Morus nigra* has been found an efficient substitute for pomegranate-root in the treatment of *tænia*.

MORPHINA, *U. S.*—MORPHINE.

Morphia, U. S. 1870; *Morphinum*, *Morphium*.—*Morphia*, E.; *Morphine*, Fr.; *Morphin*, G. Formula $C_{17}H_{19}NO_3 \cdot H_2O$. Molecular weight 303.

Origin.—Morphine is an alkaloid which has thus far only been found in opium, in the capsules of the different varieties of *Papaver somniferum*, *Linné*, and in the milk-juice of the red-flowering *Pap. orientale*, *Linné*; according to Charbonnier (1868), it is also present in *Argemone mexicana*, *Linné*. Although obtained by Derosne (1803) in an impure condition by precipitating a concentrated infusion of opium with ammonia, it was

confounded by him with narcotine. Sertürner (1816), however, not only established its difference from that body, but also proved its basic nature and its poisonous effects. Morphine was the first organic alkaloid known.

Preparation.—Take of Opium, sliced, 12 troyounces; Water of Ammonia 6 fluidounces; Animal Charcoal, in fine powder, Alcohol, Distilled Water, each a sufficient quantity. Macerate the opium with 4 pints of distilled water for 24 hours, and, having worked it with the hands, again macerate for 24 hours and strain. In like manner, macerate the residue twice successively with the same quantity of distilled water, and strain. Mix the infusions, evaporate to 6 pints, and filter; then add 5 pints of alcohol, and afterward 3 fluidounces of the water of ammonia, previously mixed with $\frac{1}{2}$ pint of alcohol. After 24 hours pour in the remainder of the water of ammonia, mixed, as before, with $\frac{1}{2}$ pint of alcohol, and set the liquid aside for 24 hours that crystals may form. To purify these, boil them with 2 pints of alcohol until they are dissolved, filter the solution, while hot, through animal charcoal, and set it aside to crystallize.—*U. S.* 1870.

This process is essentially that of Dr. E. Staples (1829). On maceration with water, the morphine, minute traces excepted, is readily dissolved, together with other constituents. To decompose the morphine salt ammonia is added; by this process the morphine is rapidly deposited, together with narcotine and some of the other alkaloids, and mixed with considerable coloring matter, from which it may be freed by repeatedly recrystallizing from dilute hydrochloric acid and expressing. Most of the coloring matter and narcotine remains in solution, and at the same time not an inconsiderable amount of hydrochlorate of morphine enters the mother-liquors, from which it may be subsequently recovered. If, however, the concentrated infusion of opium is mixed with not more than an equal bulk of alcohol, and a sufficient amount of ammonia-water is added, the morphine will be more slowly precipitated in a crystalline condition, while the great bulk of the coloring matter remains in solution. The slower the separation of the alkaloid, the larger and purer will be its crystals; hence the advantage of adding the ammonia in separate portions. Since morphine is soluble in ammonia, only sufficient of the latter should be added to unite with the acids, and if in slight excess it should be allowed to evaporate by exposure. The mother-liquid from this evaporation contains a small amount of morphine, which, when working on a larger scale, it is important to recover. The alcohol may be distilled off, and if not otherwise purified may be reserved for a similar purpose. If the process has been well conducted, the crude morphine has a light-brownish color, which is removed by dissolving in hot alcohol and treating with animal charcoal. The mother-liquor from this crystallization retains a portion of the morphine, together with the narcotine first precipitated. On distilling off the alcohol the alkaloids are obtained, and may be preserved until sufficiently accumulated for further purification. Narcotine may be separated from morphine by treatment with ether, in which the former is readily soluble, the latter entirely insoluble.

Many other processes have been proposed. As a rule, the treatment of opium with acidulated water or alcohol offers no advantages, since more narcotine and other organic compounds are thereby dissolved. Wittstock proposed to separate the narcotine from the infusion of opium by chloride of sodium, in which the narcotine is insoluble, but a little morphine is likewise liable to be deposited. The first precipitation with ammonia is sometimes effected at a boiling temperature; after cooling the morphine will be granular, and may be more advantageously washed with cold water and expressed. Precipitation with carbonate of sodium does not appear to ensure a larger yield. Pelletier observed that when acetic acid is added to crude powdered morphine until the liquid begins to retain an acid reaction, all the morphine will be dissolved, while the narcotine remains behind; and this behavior may be used for separating the two alkaloids; or the impure morphine may be completely dissolved in dilute acetic acid, the solution evaporated to dryness, and the residue treated with water, which leaves narcotine. Gregory has proposed a process which has been adopted by the British Pharmacopœia for preparing hydrochlorate of morphine from opium, and which has the advantage of dispensing with alcohol in the purification of the alkaloid. To obtain this in a pure state, the following directions are given: Take of opium, sliced, 1 pound; chloride of calcium $\frac{3}{4}$ ounce; purified animal charcoal $\frac{1}{4}$ ounce; solution of ammonia, distilled water, each a sufficiency. Macerate the opium for 24 hours with 2 pints of the water, and decant. Macerate the residue for 12 hours with 2 pints of the water, decant, and repeat the process with the same quantity of the water, subjecting the insoluble residue to strong pressure. Unite the liquors, evaporate in a water-bath to the bulk of 1 pint, and strain through calico. Pour in now the chloride of calcium, previously dissolved in 4 fluidounces of distilled water,

and evaporate until the solution is so far concentrated that upon cooling it becomes solid. Envelop the mass in a double fold of strong calico and subject it to powerful pressure, preserving the dark fluid which exudes. Triturate the squeezed cake with about $\frac{1}{2}$ pint of boiling distilled water, and, the whole being thrown upon a paper filter, wash the residue well with boiling distilled water. The filtered fluids having been evaporated as before, cooled, and solidified, again subject the mass to pressure; and, if it be still much colored, repeat this process a third time, the expressed liquids being always preserved. Dissolve the pressed cake in 6 fluidounces of boiling distilled water; add the animal charcoal and digest for 20 minutes; wash the filter and charcoal with boiling distilled water, and to the solution thus obtained add the solution of ammonia in slight excess. Let the pure crystalline morphia, which separates as the liquids cools, be collected on a paper filter and washed with cold distilled water until the washings cease to give a precipitate with solution of nitrate of silver acidulated, by nitric acid. From the dark liquids expressed in the above process an additional product may be obtained by diluting them with distilled water, precipitating with solution of potash added in considerable excess, filtering, and supersaturating the filtrate with hydrochloric acid. This acid liquid, digested with a little animal charcoal and again filtered, gives, upon the addition of ammonia, a small quantity of pure morphia.—*Br.*

In this process the morphine salts, as naturally contained in the opium, are decomposed by an excess of calcium chloride, with the formation of hydrochlorate of morphine, which, crystallizing on cooling from the sufficiently concentrated solution, produces with the calcium meconate a solid mass, from which the mother-liquor is removed by strong pressure. The pressed cake, on being treated with boiling water, yields up the morphine (and codeine) hydrochlorate, while the calcium meconate remains upon the filter. The evaporation, expression, and resolution are repeated until most of the coloring matter has entered the mother-liquors and nearly the whole of the calcium meconate remains upon the filter. The removal of the last traces of color is then effected by animal charcoal, and the morphine precipitated in a granular condition by adding a slight excess of ammonia to the boiling solution. The dark-colored mother-liquors contain, besides coloring matter and calcium salts, narcotine and morphine, which are precipitated by potassa, an excess of which dissolves the latter readily and completely, but narcotine sparingly and slowly, as observed by Robiquet, Wittstock, and others. The filtration of the strongly alkaline liquid must, therefore, not be long delayed; and when the clear liquid is acidulated with hydrochloric acid it contains morphine hydrochlorate, potassium chloride, and some coloring matter, from the last of which it is freed by animal charcoal; ammonia then precipitates the nearly pure alkaloid. The decoloration of the morphine salt by means of animal charcoal is more readily effected when in aqueous solution, as here directed, than when dissolved in alcohol.

Lime has an action upon morphine and narcotine similar to that of potassa. Couërbe has founded upon this behavior a method for preparing morphine which was somewhat modified by Mohr (1840), who directs 4 parts of opium to be exhausted by repeated boiling with water; the strained and expressed decoction is gradually added to boiling milk of lime, made of 1 part of burned lime and 8 parts of water; and after boiling for a few minutes the mixture is strained, pressed, and the undissolved portion twice boiled with a fresh portion of water. The liquid, containing mainly morphine, lime, and coloring matter, is concentrated to 8 parts, filtered, and the filtrate, while boiling, mixed with sufficient powdered sal ammoniac to convert all the lime into calcium chloride, while ammonia is given off, and the morphine on cooling separated as a granular mass; this is washed with cold water, dissolved in hydrochloric acid, purified with animal charcoal, and crystallized as hydrochlorate of morphine, or the alkaloid precipitated by ammonia. The morphine precipitated from the lime solution is darker in color than the first morphine precipitate obtained by Staples' process, but much lighter than the corresponding precipitate by Gregory's process. A modification of Mohr's process, by which the morphine is at once obtained almost free from coloring matter, has been adopted as the pharmacopœial process for assaying opium. (See OPIUM.)

Properties.—Morphine crystallizes in short, transparent, and colorless or white prisms or needles, which require for solution 10,000 parts of cold and 460 parts of boiling water. Chastaing (1882) ascertained that 1 liter of water dissolves at 10° C. (50° F.) 0.1 Gm., at 20° C. (68° F.) 0.2 Gm., at 30° C. (86° F.) 0.3 Gm., and at 100° C. (212° F.) 2.17 Gm., of morphine. At or near 15° C. (59° F.) the alkaloid is stated to be soluble in 100 parts (*U. S.*), 90 parts (Merk), 42 parts (Choulant) of alcohol, and at the boiling temperature in 36 parts (*U. S.*, Choulant), 24 parts, of alcohol (Bucholz).

Duflos found it soluble in 20 parts of cold and 13.3 parts of boiling absolute alcohol; Pectenkofer, in 40 and 30 parts respectively. Prof. Prescott (1875) determined morphine to be soluble in the following quantities of hot liquids: in 6148 parts of ether sp. gr. .729, in 4379 parts of chloroform sp. gr. 1.4953, in 8930 parts of benzol sp. gr. .8766, and in 91 parts of amyl alcohol sp. gr. .8316; all except the last liquid dissolved from four to five times more of the nascent alkaloid. Chloroform containing 7 per cent. of alcohol dissolves $\frac{1}{156}$ of morphine (Vander Burg, 1879). Reveil (1863) found morphine to be soluble in 220 parts of glycerin. It is soluble in about 400 parts of cold amyl alcohol and 500 parts of acetic ether, in fixed alkalies and alkaline earths, less so in ammonia (117 parts), and still less in ammoniacal salts, but nearly insoluble in fixed oils. The alkaloid is not altered by exposure to air, and is inodorous, and at first tasteless, developing, however, a bitter taste. Its solutions have an alkaline reaction upon test-paper, and with acids it yields salts, most of which are crystallizable. Heated to 120° C. (248° F.), it loses 5.95 per cent. of water of crystallization and fuses to an oily liquid, which crystallizes on cooling; at a higher heat it is decomposed, and burns without leaving any residue.

Reactions.—Commercial concentrated sulphuric acid dissolves morphine with a yellowish afterward gray color. Pure morphine yields with pure sulphuric acid a colorless solution, and when heated to 100° C. (212° F.) for half an hour is colored pink-red (Prescott, 1877). Mixed with six or eight times its weight of sugar, morphine acquires with sulphuric acid a bright purple-red color, gradually changing to violet-blue, blue-green, and dingy-yellow (Schneider, 1872). The delicacy of this test is increased by the addition of a little bromine-water, so that .00001 Gm. of morphine will still show a rose-red color (Weppen, 1874). Concentrated nitric acid imparts a blood-red color, changing to orange and yellow. Dissolved in sulphuric acid and the solution heated to near 150° C. (302° F.), the addition of a little nitric acid colors violet-blue, changing quickly to blood-red, and afterward to deep orange (Husemann, 1863). *Fröhde's reagent* (1866) (6.001 to 0.005 sodium molybdate in 1 Cem. H_2SO_4) acquires a beautiful violet color, changing to blue, olive-green, yellow, and in 24 hours to purplish-blue. In the reaction of this reagent upon many alkaloids and other organic substances a light- or dark-blue or more or less green color is produced; the changes in color must, therefore, be noticed, and a larger amount of the molybdate in the test carefully avoided. (See papers by Buckingham, Wellcome, and Prescott in *Amer. Jour. Phar.*, 1873, p. 150; 1876, pp. 21, 59.) Chlorine-water added to morphine causes a yellow or orange color, which is deepened by alkalies; chlorinated alkalies or lime at once produce the orange color. Morphine decomposes iodic (Serullus) and periodic (Boedeker) acids, liberating iodine; in dilute solutions the addition of sulphuric acid is advisable; ammonia deepens the yellow color of the solution. Solutions of silver nitrate, gold chloride, potassium ferricyanide, cuprammonium, and chromic acid are reduced by morphine and its salts. Ferric chloride colors morphine and its salts deep-blue, the color being destroyed by free acids and alcohol, but not by alkalies (Robinet). Pellagri (1877) recommended a test which depends upon the production of apomorphine (see p. 220), and is applied as follows: The suspected substance is dissolved in concentrated hydrochloric acid, a little sulphuric acid is added, and the solution evaporated at 100° C.; a purple color will be produced. To the residue is added a little hydrochloric acid, then bicarbonate of sodium, and finally a strong solution of iodine in hydriodic acid, when a green compound is produced, dissolving in ether with a purple color.

The *salts of morphine* are precipitated from their solutions by the alkalies and alkaline earths, the precipitates being soluble in an excess of the precipitant. Similar precipitates are produced by the alkaline carbonates and cyanides, but the alkaline bicarbonates fail to precipitate acid solutions in the cold. Tannin causes a white precipitate soluble in acetic acid, in mineral acids, and in alcohol. Auric or platinum, but not mercuric, chloride occasions a yellow precipitate. The acidulated solutions of morphine are precipitated by potassio-mercuric iodide, potassio-cadmium iodide, and other general reagents for alkaloids; the precipitate with phosphomolybdic acid turns blue with cold sulphuric acid and brown on warming. 1 Cem. of Mayer's test solution precipitates 0.020 Gm. morphine. When a salt of morphine is heated with an excess of sulphuric or hydrochloric acid to near 150° C. (302° F.), the alkaloid parts with H_2O and is converted into apomorphine, $C_{17}H_{17}NO_2$ (see page 220).

Beckett and Wright (1875) ascertained that morphine treated with acetic, benzoic, or butyric anhydride is converted into derivatives containing acetyl, benzoyl, or butyryl in the place of 1 or 2H. Hesse (1883) obtained similar compounds with propionic anhy-

dride at 85° C. (185° F.). *Diacetyl-morphine* and the analogous derivatives are not colored by ferric chloride, and are decomposed into morphine and the corresponding acids on being warmed with alcoholic solution of potassa.

Tests.—When heated upon platinum-foil, no fixed residue should be left (lime, magnesia, etc.). On dissolving 1 part of morphine in 20 parts of solution of soda or potassa, no insoluble residue should be left (narcotine and other alkaloids); and the liquid should remain colorless (glucose, etc.), and should not give off ammoniacal vapors (ammonium salts). “Morphine should yield a colorless solution with cold concentrated sulphuric acid, which should not acquire more than a reddish tint by standing for some time (narcotine, thebaine, etc.), and which should not assume a purple or violet, but merely a greenish, color on the addition of a small crystal of chromate of potassium (absence of and difference from strychnine, brucine, etc.).”—*U. S.*

Pharmaceutical Uses.—The alkaloid is used in preparing morphine salts.

Physiological Action.—*On Animals:* As the effects of the several salts of morphine are nearly identical, it will be convenient to study them in connection with the alkaloid itself. The first remark is that birds, in many instances, tolerate the action of morphine, when taken into the stomach, to an almost incredible degree; thus it has been found that of two pigeons one might survive a dose of 12 grains, while it would prove fatal to the other bird. Even hypodermically 3 grains were required to destroy life. In these animals morphine appears to act upon the spinal marrow rather than upon the brain, causing unsteady movements, partial paralysis, and general convulsions. Analogous results have followed experiments upon rabbits, dogs, and horses. Thus, 6 grains of acetate of morphine administered to a dog caused paralysis of the hind legs, salivation, somnolency, and *dilated* pupils, but the animal recovered. A like result followed the administration of 12 grains of morphine to a horse. It should, however, be stated that in exceptional cases morphine has appeared to produce true, and even fatal, narcotism in birds. So, too, in certain experiments upon dogs a true narcotic operation has been observed; on awaking, the animals looked terrified and haggard, dragged their hind legs, failed to recognize their masters, and slunk into a dark corner, where they remained for many hours and until the intoxication had entirely passed away. The rationale of its action upon animals may, according to Witkowski, be expressed in the following propositions: 1, Morphine paralyzes the cerebral centres of sensation and motion in the brain; 2, the paralysis of these centres is preceded by their excitement; 3, this paralysis precedes that of the respiratory centres; 4, the centres of the inhibitory vagus fibres, the vascular nerves, and those which contract the pupil are neither depressed nor stimulated by morphine; 5, spinal reflex excitability is heightened by it; and 6, the peripheral nerves are in no manner affected by morphine. According to Curci (*Centrabbl. f. d. ges. Thérapie*, ii. 72), morphine slows the pulse, especially in the first stage of its operation—in moderate doses rapidly, but slightly diminishing the blood-pressure at first, then increasing it, and finally lessening it during full narcosis.

On Man: The general effects of morphine on the system are almost identical with those of opium, but there are some points of difference which call for notice, and some peculiarities depending upon the manner in which morphine is administered. It does not appear to stimulate the nervous system or the circulation as much as opium, nor display so decided a narcotic influence. It has been remarked that although 2 or even 3 grains of opium certainly contain less than a grain of morphine, yet their action is more intense, rapidly occasioning a degree of narcotism bordering upon coma, but soon subsiding without leaving decided secondary effects behind; while morphine does not so readily produce narcotism, but its after-effects are of longer duration. Opium also increases the temperature as well as the sense of heat, but morphine, while agreeing in the latter effect, lowers the temperature. So, too, opium primarily increases the frequency of the pulse, but morphine diminishes it. Opium is less apt to excite nausea and vomiting than morphine. Of this operation it has been remarked that women are much more liable to it than men, and especially to vomiting. When morphine is used hypodermically such effects usually take place immediately, but when given by the stomach they may not appear for several days. A corresponding contrast is presented by its action on the bowels: by the hypodermic method morphine continues to constipate, but by the mouth it tends to occasion diarrhœa after a few days. Under like circumstances opium does not cause looseness of the bowels, but ceases to confine them. Contrary to the general opinion, morphine does not, according to Rutherford's experiments, affect the secretion of bile. The experiments of Filhene (*Archiv. f. Pathol. u. Pharmacol.*, xi. 60) led him to a conclusion in harmony with general clinical experience—viz.

that when respiration is interfered with by anæmia of the medulla oblongata, without previous pulmonary obstruction, the use of morphine in doses capable of restoring the act of respiration to its normal type is thoroughly indicated. But when, on the other hand, an obstacle to the arterialization of the blood exists in the lungs themselves, then morphine must be circumspectly used. Berkart, in like manner, teaches that when the pulmonary obstruction originates in the heart itself, it may often be overcome by stimulation of the heart; and no better agent can be resorted to for that purpose than morphine in small doses, administered hypodermically. Morphine is very apt to occasion ardor urinae, with vesical irritation and diminished secretion of urine. The last symptoms may be accounted for, in part, by the profuse sweating that often follows the administration of morphine in full doses. It is said to be more marked in females than in males. Although itching of the skin sometimes attends the action of opium, it is usually insignificant compared with that which morphine frequently causes. It generally begins in the eyes and nose, and often extends to the whole surface of the body, causing great restlessness and distress. Along with this symptom, or independently of it, various fugitive eruptions appear of a papular or erythematous description, and especially urticaria. They probably depend upon the same immediate cause that provokes diaphoresis, and they have been oftener noticed after the hypodermic use of morphine than otherwise. Among many instances the following may be cited in illustration: In a case of sciatica Comanos used a hypodermic injection of $\frac{1}{4}$ grain (Gm. 0.02) of morphine. The next day the whole skin was covered with a scarlet rash, the temperature was 102° F., and at the end of 4 days desquamation took place. Some time afterward the same dose was given by the mouth, and produced a similar febrile eruption; and later an ointment containing morphine was rubbed into the skin over the painful nerve, and after several days an eruption broke out as before, and then a large carbuncle formed (*Berlin klin. Wochensh.*, No. 42, 1882). As with all narcotics, so with morphine: if it is left off abruptly, wakefulness and restlessness, with nervous depression, are apt to ensue. The fatal dose of morphine cannot be determined; it may not exceed a single grain, and, on the other hand, a case is recorded in which 7 grains of morphine were taken in the form of Magendie's solution, and yet by dint of powerful excitation, chiefly electrical, the patient recovered (Schweig). An infant fourteen days old recovered after taking $\frac{1}{4}$ grain of morphine, and another three weeks old after taking a teaspoonful of wine of opium (*Boston Med. and Surg. Jour.*, July, 1880, p. 57). In another case it is said that 10 grains were taken, but the patient recovered after the hypodermic injection of atropine (*Med. News*, xli. 592).

The influence of morphine used habitually by hypodermic injection is most pernicious. Even in dogs, after a time emaciation sets in and ultimately reaches an extreme degree; the animal is habitually torpid, the skin of the feet grows morbidly sensitive, and the temperature is very low. After death the brain and spinal marrow are anæmic and the lungs and liver engorged. In man the effects are similar, but those of the intellectual sphere are predominant. They include nervousness, tremor, hyperæsthesia, spasms, neuralgia, insomnia, anxiety, hypochondria alternating with excitement, hallucinations, a suicidal tendency, dryness of the tongue, constipation, and scanty urine, with vesical irritation, and sometimes albuminous urine. It also blunts the perception of duty, gratitude, and even delicacy, and perverts the sense of truth. No doubt those effects are due in part to the efforts made by the slave of the morphine habit to conceal his illicit indulgence or its degree, but they are chiefly attributable to the obtuseness which it creates in the moral faculties as well as the senses. If the drug is abruptly withdrawn, the patients suffer a collapse, with indescribable distress from nervousness and loss of self-control, profuse sweats, or diarrhœa and a dusky discoloration of the face. The tolerance of morphine in some cases of its habitual use is extremely remarkable, as the following summary will prove: A man gradually increased his daily dose until at the end of 2 years it reached 40 grains (Siredey). A woman who used morphine hypodermically at last took 14 grains every day. Except habitual lassitude of mind and body no bad effect of any kind was produced (Braithwaite). But the most singular instance of this nature is one reported by Dr. Lyman of Boston: A woman forty-seven years of age had been addicted to the morphine habit since the age of eighteen. She was in good flesh, though a small eater and with an indifferent appetite; she experienced no disorder of the heart or kidneys, her bowels were moved by the help of injections, and her catamenia were always regular. Yet throughout this long period of 28 or 29 years her daily dose of morphine averaged about 16 grains. A woman aged sixty-six years often had three hypodermic injections daily, each of 6 grains of morphine (*Practitioner*, xxv. 66). Another habit-

usually took this amount internally, and occasionally doubled it. During one period of 3 weeks she took a drachm of morphine daily, and on several days 80 grains (*Boston Med. and Surg. Jour.*, Feb. 1882, p. 128). In some persons almost every hypodermic injection is followed by an abscess. We are familiar with the case of a lady who for several years was subject to violent attacks of neuralgia of the face and head, for which she was treated by hypodermic injections of morphine. Almost all the punctures were followed by abscesses, and both of her arms from the shoulders almost to the wrists are deformed by the scars they left behind them. According to Obersteiner, about 74 per cent. of the victims of the morphine habit are males, and of these nearly 47 per cent. are medical men.

Many cases occur in which idiosyncrasies modify the usual effects of morphine. In some it causes violent mental excitement, hallucinations, and a total inability to sleep; in others it occasions nervous depression, syncope, pallor of the skin, feebleness of the pulse, dyspnoea, insensibility, urgent vomiting, etc.; in others, again, spasmodic movements or a fully-formed tetanoid paroxysm (*British Med. Jour.*, Oct. 18, 1879). No doubt some of the most alarming examples of this nature have followed the hypodermic injection of morphine, either because of the swift absorption of the narcotic or from its having been thrown into a vein. Hence the wisdom of the rule to introduce morphine hypodermically with great deliberation, and of the advice that has been given to associate with each injection $\frac{1}{96}$ grain of atropine to counteract the depressing and nauseating effects of the morphine. This dose should never be repeated while the effects of a previous dose appear to be increasing. In all cases the condition of the pulse and the heart should be considered. Not a few examples are recorded of death by syncope immediately after the administration of morphine hypodermically, and many also in which death seemed imminent. In one case, among others, a case of lumbago, this effect resulted from the hypodermic injection of $\frac{1}{4}$ grain of morphine at a spot midway between the spine and the crest of the ilium. In about 10 minutes collapse with syncope occurred, and the patient was with difficulty saved (*Boston Med. and Surg. Jour.*, Oct. 1879, p. 619). The administration of chloroform to a person under the full influence of morphine is peculiarly dangerous. Even ether should be cautiously employed, especially if severe pain is suffered (*Med. Record*, xxii, 274). The immediate and remote effects of the hypodermic use of morphine and of the "morphine habit" have been fully depicted by numerous writers. To their works the reader is referred (Burkart, *Die chron. Morphia Vergiftung*, 1877-78; Pétit, *Bull. de thérap.*, vol. xvi.; Levinstein, *Die Morphiomsucht*, 1880; Obersteiner, *Med. News and Abst.*, July, 1880, p. 438, and *Wiener klinik*, Marz, 1883; Kane, *Morphia Hypodermically*, 1880).

Medical Uses.—Although morphine may, in general terms, be used for the same purposes as opium, which are fully treated of elsewhere (see OPIUM), and especially as an internal medicine, it is true, nevertheless, that the introduction of the hypodermic method of employing it has shown its fitness for certain special conditions. This method is superior to any other when the prompt action of the medicine is necessary to save life or lessen pain, when the patient is unable or unwilling to swallow, and when a local rather than a general influence is sought. The use of morphine, and especially its hypodermic use, in the treatment of *insanity*, while it is unquestionably preferable to allowing the insane to become exhausted by excessive mental and physical exertion, is just as certainly abused to save trouble for physicians and attendants. Very often the disease, whether it have a physical basis or not, is fostered and prolonged by this method, which is really but little better than the strait-jacket, the tranquillizing-chair, and other instruments of torture which are now seldom used in asylums which are managed by a sound intelligence. And hardly less mournful is it to know that in these institutions the baleful habit of morphine-intoxication has often been formed. Undoubtedly, a wise and prudent use of this remedy is most advantageous, especially in cases of transient or of periodical mania, or when it is attended by severe bodily pain, provided that the administration be absolutely controlled by a responsible physician and not trusted to inexperienced assistants or ignorant or unfaithful nurses. (Compare Voisin, *Bull. de thérap.*, c. 385, 443.) In *stroke* attended with convulsions, jactitation, delirium, and general excitement the hypodermic injection of a salt of morphine, in the dose of $\frac{1}{4}$ grain, affords prompt relief. In *epileptiform convulsions* due to mental excitement, in pregnancy and the *puerperal state*, in *hysteria* and aggravated *chorea*, in various *local spasms*, as of the face, glottis, diaphragm, etc., this remedy should always be borne in mind. Morphine hypodermically employed is perhaps the best remedy in *tetanus*, even of the traumatic form, and a like statement is true of the analogous condition caused by *strychnia*-poisoning. It is the proper antidote in *poisoning by belladonna* or atropine. Of all the reme-

dies for *spasmodic asthma* this one procures incomparably the most speedy relief. Nor is it only in *spasmodic dyspnoea* that the treatment is efficient. Hucliard, among others, contends that, with rare exceptions, this symptom is by itself an indication for the use of hypodermic injections of morphine (*Bull. de thérap.* xevi. 477). The attacks of dyspnoea due to mitral obstruction are less amenable to this medicine than any other, whether cardiac, pulmonary, or nervous (*Ibid.*, c. 173). The pain of *neuralgia*, especially in its severer forms, such as affect the fifth nerve, the sciatic, and the gastric nerves, is promptly palliated by it. In neuralgia of the superficial nerves rapid vesication of the skin over the painful points, and the application to the cutis of a strong solution or ointment containing a morphine salt, may also be employed, but its effect is less prompt and sure than the hypodermic plan. Of all palliatives employed in that most terrible of pains, *angina pectoris*, none affords more prompt and sure relief, not only subduing the neuralgic anguish, but calming the tumultuous and disordered movements of the heart. It has the advantage over other methods of being almost free from danger. One of the best occasional remedies for *nervous headache* which females are apt to experience during the menstrual periods is a cup of strong coffee with $\frac{1}{2}$ grain of a morphia salt, but it is a remedy which is not to be recommended for general or frequent use. The hypodermic injection of morphine is the promptest of all palliatives for *muscular rheumatism*, and especially for *lumbago*. The use of morphine as an antidote to poisoning by BELLADONNA, ATROPINA, and CALABAR BEAN is considered under those several titles. It may, however, be mentioned in this place that the antagonism in question may sometimes be usefully employed to meet special indications. Thus, morphine, which is so essential to moderate cough in phthisis, and which is at the same time contraindicated by its tendency to produce sweating, may, if associated with a minute proportion of atropine, fulfil its important object without inducing profuse diaphoresis. In like manner, the depressing influence of morphine, which renders it dangerous in certain cases of extreme exhaustion accompanied with severe pain, may be counteracted by giving atropine along with it (Fothergill).

Like all new methods, the hypodermic use of morphine has been greatly perverted; the prompt alleviation of pain and the pleasing intoxication which follows form too strong a temptation to its use for all persons to resist successfully. Like alcohol, its intoxication leaves behind it a sense of debility and depression which nothing but a fresh resort to the medicine relieves. If continuously employed, it creates an artificial necessity for resorting to its powerful and genial support, and the longer it is used the larger is the dose of it required. A peculiar allurement of the habit as compared with that of taking opiates by the mouth is that in many cases it does not so readily derange the stomach, impair the appetite, or produce constipation. These effects should be borne in mind, but it is equally important to remember that in cases of hopeless disease the duty of the physician is, above everything else, to relieve his patient's suffering.

The average *dose* of morphine or of its salts is about $\frac{1}{2}$ grain (Gm. 0.013), but morphine uncombined is seldom prescribed. For hypodermic uses an officinal solution of acetate of morphine has been provided by the British Pharmacopœia. (See INJECTIO MORPHINÆ HYPODERMICA.) It is said that if the morphine solution is heated in a spoon before being injected, organic growths that may have formed in it will be destroyed, and the solution will then become less irritating. The tartrate has been proposed as superior to any other salt of morphine for hypodermic injection. It is said to be entirely bland and unirritating, and that its solution can be kept fresh for any length of time (Stuart).

MORPHINÆ ACETAS, U. S., Br.—ACETATE OF MORPHINE.

Morphiæ acetat, *Morphinum* (s. *Morphium*) *aceticum*, *Acetas morphinæ*, *Acetas morphicus*.—*Acetate of morphia*, E.; *Acétate de morphine*, Fr.; *Morphinacetat*, *Essigsanres Morphin*, G.

Formula $C_{17}H_{19}NO_3 \cdot C_2H_4O_2 \cdot 3H_2O$. Molecular weight 399.

Preparation.—The British Pharmacopœia, not recognizing morphine as officinal, directs that alkaloid to be prepared from 2 ounces of the hydrochlorate by precipitating its solution with ammonia and washing the precipitate with distilled water; the moist morphine is diffused in 4 ounces of water, dissolved by neutralizing with acetic acid, the solution evaporated on a water-bath until it concretes on cooling, and the mass dried with a gentle heat and reduced to powder. The salt should be kept in small well-stopped vials. A very slight excess of acetic acid is rather of advantage, since the salt begins to decompose during the evaporation by the liberation of a little acid; it is therefore

advisable to facilitate evaporation at a rather low temperature by means of a current of air. The salt may be crystallized with some difficulty in the form of white silky needles, but is very generally obtained in powder as directed above.

For obtaining the salt of very handsome appearance Hager gives the following directions: Rub 10 parts of pure morphine to powder, keeping it moist by the addition of a little alcohol, and add 25 parts of glacial acetic acid, triturating constantly; then drop alcohol into the mixture until it has become of a syrupy consistence, and afterward ether until the color of the mixture has changed to milk-white; after two or three days the solidified mass is loosened in the mortar and turned, and when completely dry is rubbed to powder and preserved.

Properties.—Acetate of morphine forms a white mostly amorphous powder which has a slight acetous odor and very bitter taste. Belohoubek (1880) found in the crystallized salt two forms of needles—the first transparent and distinct, the other white, opaque, and aggregated to tufts. When freshly prepared, the salt dissolves at 15° C. (59° F.) in 12 parts of water and 68 parts of alcohol (*U. S. P.*), in 45 parts of alcohol (Hager), and at the boiling-point requires 1.5 parts of water and 14 parts of alcohol (*U. S. P.*), 2 parts of alcohol (Hager). The salt is soluble in 2.44 parts of water (Dott, 1881–82), in 60 parts of chloroform, and is insoluble in ether. The alcoholic solution, mixed with an excess of ether, deposits crystals of morphine, free acetic acid remaining in solution. Cold strong sulphuric acid dissolves the salt without color only when recently made. When kept on hand it slowly loses acetic acid; its reaction to test-paper changes from neutral to alkaline, and the salt becomes incompletely soluble in water unless a little acetic acid be added; it gradually acquires a yellowish-gray, and finally brownish, color, and should then be redissolved in acetic acid and evaporated or converted into another salt of morphine. Its aqueous solution undergoes similar changes, the acetic acid being slowly decomposed, with the separation of brown flocculent compounds, while the morphine crystallizes out, forming long prisms if the solution is not disturbed. The formula given by the Pharmacopœia is that of Oudemans (1873), and requires 71.4 per cent. of anhydrous or 75.94 per cent. of crystallized morphine. Kieffer (1857) found the salt to contain 79.8 per cent. of morphine.

Tests.—The salt responds to the morphine tests described above, and leaves no residue when ignited. If its solution is precipitated by tannin, the addition of dilute hydrochloric acid redissolves the precipitate; solution of potassa or soda gives a white precipitate soluble in excess of the alkali; a remaining turbidity would indicate the presence of narcotine. Sulphuric acid added to the salt liberates acetous vapors.

Off. Prep.—Liquor morphiæ acetatis, *Br.*

Medical Uses.—The action and uses of the acetate are the same that have been described in the article on MORPHINA. The dose of the acetate is about $\frac{1}{8}$ grain (Gm. 0.01).

MORPHINÆ HYDROCHLORAS, *U. S.*, *Br.*—HYDROCHLORATE OF MORPHINE.

Morphiæ hydrochloras, *Br.* 1867; *Morphiæ murias*, *U. S.* 1870; *Morphinum hydrochloricum*, *P. G.*; *Murias (Hydrochloras) morphiæ*.—*Muriate of morphia*, *E.*; *Chlorhydrate de morphine*, *Fr.*; *Morphinhydrochlorat*, *Salzsaures Morphin*, *G.*

Formula $C_{17}H_{19}NO_3.HCl.3H_2O$. Molecular weight 375.4.

Preparation.—The British Pharmacopœia has a process for preparing this salt from opium, which was given under MORPHINA, as far as the precipitation of pure morphine. The remaining steps are as follows: “Diffuse the pure morphia (obtained from 1 pound of opium) through 2 fluidounces of boiling distilled water placed in a porcelain capsule kept hot, and add, constantly stirring, the diluted hydrochloric acid, proceeding with caution, so that the morphia may be entirely dissolved and a neutral solution obtained. Set aside to cool and crystallize. Drain the crystals, and dry them on filtering-paper. By further evaporating the mother-liquor and again cooling additional crystals are obtained.” If pure morphine has been used and an excess of hydrochloric acid avoided, the salt may be wholly obtained in crystals by judicious evaporation of the mother-liquor. On account of the greater stability of this salt and of its solution, the German Pharmacopœia directs it to be dispensed whenever acetate of morphine is prescribed.

Properties.—Hydrochlorate of morphine crystallizes in white silky, flexible, and inodorous needles or transparent prisms having a bitter taste and neutral reaction. It is soluble in 20 parts of cold (24 parts at 15° C. *U. S. P.*; 25 parts *P. G.*; 23.9 parts,

Dott, 1882) and in less than its own weight (about 0.5 parts *U. S. P.*) of boiling water; in 60 parts of cold and in 10 parts of boiling 80 per cent. alcohol (Wittstein); in 63 parts (48 parts, Candidus, 1882) of alcohol at 15° C., and in 31 parts of boiling alcohol (*U. S. P.*); in 50 parts of alcohol sp. gr. .832 (*P. G.*); in 19 parts of glycerin and in 800 parts of olive oil; it is insoluble in ether. Heated to 100° C. (212° F.), it loses 14.38 per cent. of water of crystallization (Tausch, 1880). It yields 75.9 per cent. of anhydrous and 80.7 per cent. of crystallized morphine. On triturating the salt with sulphuric acid and sprinkling bismuth subnitrate upon the mixture, a dark-brown color is produced (*P. G.*).

Tests.—The salt should not have an acid reaction, and should answer to all the morphine tests described before; its aqueous solution yields with nitrate of silver a white precipitate, which is insoluble in nitric acid, but dissolves in ammonia. When heated to 130° C. (266° F.) the pure salt remains white, while the commercial salt generally turns brown or black from the decomposition of resinous substances present (Tausch, 1880). When ignited, the salt should leave no fixed residue.

Off. Prep.—*Injunctio morphinæ hypodermica*, *Liquor morphinæ hydrochlor.*, *Supposit. morphinæ*, *Suppos. morphinæ cum sapone*, *Trochisci morphinæ*, *Troch. morphinæ et ipecacuanhæ*, *Br.*

Medical Uses.—The operation of the hydrochlorate of morphine is identical with that of the acetate, and its *dose* is the same, or about $\frac{1}{2}$ grain (Gm. 0.01).

MORPHINÆ SULPHAS, *U. S.*, *Br.*—SULPHATE OF MORPHINE.

Morphinæ sulphas, *U. S.* 1870; *Morphinum sulfuricum*, *P. G.*; *Sulfas morphiæ*.—*Sulphate of morphia*, *E.*; *Sulfate de morphine*, *Fr.*; *Morphinsulfat*, *Schwefelsaures Morphin*, *G.*

Formula $(C_{17}H_{19}NO_3)_2H_2SO_4 \cdot 5H_2O$. Molecular weight 758.

Preparation.—This salt may be prepared in the same manner as the hydrochlorate. 1 ounce of pure morphine is diffused in 2 ounces of boiling distilled water, and diluted sulphuric acid is cautiously added until the alkaloid is dissolved and the liquid has a neutral reaction to test-paper: it is then allowed to cool and crystallize: the crystals are drained and dried, and the mother-liquor concentrated to obtain an additional crop of crystals.

The importation of morphine and its salts into the United States amounted to somewhat over 3000 ounces annually in 1879 and for some years previous, but has been much larger since, and was 23,239 ounces in 1882.

Properties.—Sulphate of morphine crystallizes in white fascicles of transparent silky, inodorous, and bitter needles, which are neutral to test-paper, and are not altered on exposure to air. At 120° C. (248° F.) it parts with 4 molecules of water (Liebig), but on being heated to 130° C. (266° F.) it loses 11.87 per cent. of water of crystallization, becoming anhydrous (Regnault); the exsiccated salt absorbs water on exposure (Liebig). The crystallized salt dissolves in 23.01 parts of water at 15° C. (59° F.), as was determined by Dott (1881–82). The somewhat greater solubility of some samples of morphine sulphate (Von Coblentz in 1882 found some to be soluble in 18 and 19 parts of water) may be due to the presence of other alkaloidal salt or of an excess of acid. Choulant's statement (1818), that morphine sulphate dissolves in 2 parts of water, refers to a salt which was said to contain 40 morphine, 22 sulphuric acid, and 38 water of crystallization. The official salt dissolves in 0.75 parts of boiling water, in 702 parts of alcohol at 15° C., and in 144 parts of boiling alcohol (*U. S. P.*); Hager states it is readily soluble, and P. C. Candidus (1882) found it to dissolve in 40 parts of alcohol. It dissolves in 5 parts of glycerin (Reveil, 1863), but is insoluble in ether. The salt represents 75.2 per cent. of anhydrous and 79.94 per cent. of crystallized morphine. Its aqueous solution yields a white precipitate with chloride of barium, insoluble in nitric acid. Dott (1877) noticed an article sold in England which was adulterated with 34.63 per cent. of anhydrous sodium sulphate.

Tests.—Sulphate of morphine should have a neutral reaction to test-paper, should show the behavior of morphine salts described in the article on MORPHINE, and should leave no fixed residue when ignited.

Off. Prep.—*Pulvis morphinæ compositus*, *Trochisci morphinæ et ipecacuanhæ*, *U. S.*

Other Salts of Morphine.—MORPHINÆ HYDROBROMAS, $C_{17}H_{19}NO_3HBr \cdot 2H_2O$; mol. weight, 401.8. This salt is prepared by dissolving the alkaloid in warm hydrobromic acid or by double decomposition between alcoholic solutions of 6 parts of potassium bromide and 19 parts of sulphate of

morphine, and by evaporating the filtrate from the precipitated potassium sulphate. E. Schmidt (1877) found it to crystallize in long white needles, which are more soluble in water than the hydriodate, and become anhydrous at 100° C. According to Latour, it contains $3\text{H}_2\text{O}$, and requires 25 parts of water at 15° C. for solution.

MORPHINE HYDRIODAS, $\text{C}_{17}\text{H}_{19}\text{NO}_3 \cdot \text{HI} \cdot 2\text{H}_2\text{O}$; mol. weight, 448.6. It is prepared, like the preceding, from morphine and hydriodic acid, or from 4 parts of potassium iodide and 9 parts of sulphate of morphine. A concentrated solution of potassium iodide, added to a solution of acetate or hydrochlorate of morphine, separates the same salt. It crystallizes in long silky needles, parts with its water at 100° C., and recombines with it on exposure to air. Prepared by either process, Schmidt found it to have the above formula and to be sparingly soluble in cold water.

MORPHINE TARTRAS ($\text{C}_{17}\text{H}_{19}\text{NO}_3$) $_2$ $\cdot \text{C}_4\text{H}_6\text{O}_6 \cdot 3\text{H}_2\text{O}$; mol. weight, 774. On dissolving 4 parts of morphine with 1 part of tartaric acid in 20 parts of hot water, the greater portion of the salt crystallizes on cooling in small needles. It is somewhat efflorescent in dry air, loses at 130° C. 6.76 per cent. of water, is soluble in alcohol, and dissolves in 9.7 parts of water at 15° C. (Dott, 1882); the aqueous solution is not precipitated by alkalis, alkali carbonates, or calcium chloride (Arppe). The salt represents 78.3 per cent. of crystallized morphine.

MORPHINE MECONAS ($\text{C}_{17}\text{H}_{19}\text{NO}_3$) $_2$ $\cdot \text{C}_7\text{H}_4\text{O}_7 \cdot 5\text{H}_2\text{O}$; mol. weight, 860. This salt is present in opium, and may be prepared by neutralizing morphine with meconic acid. According to Robiquet, it is uncrystallizable and is readily soluble in alcohol, and, according to Dott (1882), dissolves in 33.9 parts of water at 15.5° C. (60° F.).

Medical Uses.—Sulphate of morphine is more generally used than any of the other salts of this alkaloid. Its *dose* is about $\frac{1}{2}$ grain (Gm. 0.01).

MOSCHUS, U. S., Br.—MUSK.

Musc, Fr.; *Moschus*, G.

The dried secretion from the preputial follicles of *Moschus moschiferus*, Linné.
Class Mammalia. Ord. Ruminantia.

Origin.—The musk deer resembles the deer (*Cervus*), but differs from it in the want of horns, and in the canines, which are long and project considerably downward from the lips of the male. It inhabits chiefly the mountainous regions and elevated table-lands of Central Asia, and is met with from Anam, in Farther India, north-westward to Thibet, and northward in China and Tartary to Mantchooria and Southern Siberia. It lives in pine forests in the Himalayas, frequently at an altitude of 10,000 to 14,000 feet (3000–4260 M.). The musk-sac is found in the male only, and is located on the abdomen, immediately before the preputial orifice and to the rear of the umbilicus. The animal has nocturnal habits, and is taken by snares and pitfalls, or sometimes by shooting; the sac is cut off as soon as possible, and rapidly dried by pressing it against heated stones. 6883 ounces of musk and civet have been annually imported during the past eight years.

Description.—The musk-bag (called sac, pod, or pouch) is oval in shape, about 2 inches (5 Cm.) long and $1\frac{1}{2}$ inches (38 Mm.) wide, with a thickness of about half an inch (13 Mm.). The upper surface is smooth and flat, the lower surface convex and hairy. The hairs are grayish and brown, rather stiff and appressed, and arranged in a circle toward the aperture near the centre of the bag, and in the form of a pencil toward the preputial orifice, which is about $\frac{1}{4}$ inch (6 Mm.) in the rear of the former. From this orifice, underneath the hairy skin between the strata of the muscular coat and toward the posterior end of the sac, is a canal containing the front portion of the thin penis. Following the muscular coat is the musk-pouch proper, with an external fibrous coat, having on the inner surface numerous depressions resembling meshes and surrounded by folds, and covered by two coats—the one soft and pearly, and the other very delicate, silvery-white on the outside, and yellowish or brownish on the inside. The musk is supposed to be separated by a number of glands, of which two or more are situated in each depression. In the young animal the secretion is slight and of a milky appearance, but after it has passed its third year the musk is of better quality; in the fresh state it is of an unctuous consistence.

FIG. 186.

Musk Deer.

FIG. 187.

Lower surface.

FIG. 188.

Upper surface.

Chinese musk-sac.

From a record kept by Messrs. Cramer and Small (*Amer. Jour. Phar.*, 1872, p. 565) the average weight of Chinese musk-bags was found to be 394 grains, and of the musk in each 157 grains.

Musk is of a crummy appearance, near the musk-orifice mixed with grayish hairs of a reddish-brown color or darker brown, and irregularly granular, somewhat unctuous to the touch, of a strong, diffusible, and persistent odor, and of a bitterish taste. When entirely exsiccated it is almost inodorous, but the odor reappears on moistening, and is increased by the addition of a little alkali. Musk should be kept in not too warm a place, where the air has some access to it. The German Pharmacopœia now requires it, for medicinal use, to be dried over sulphuric acid until it ceases to lose weight. Its odor disappears or is more or less modified on triturating the musk with camphor, oil of bitter almond, fennel, ergot, mustard, sulphur, acids, various salts, etc.

Varieties.—Several varieties are known in commerce, the best being the *Chinese*, *Thibet*, or *Tonquin* musk. It is usually imported in small boxes, internally lined with sheet lead and containing about twenty-five sacs, each wrapped in paper. The outer hairs are trimmed short, and are of a yellowish or grayish color. Musk enters commerce through the Chinese ports. *Siberian musk* comes by way of St. Petersburg, hence the name *Russian musk*; it often resembles and has the same quality as the preceding; when in flatter ovate sacs with thinner and paler hairs, and of fainter, less aromatic, and more urinous odor, it is called *Cabardine musk*. The small and inferior *Bucharian* and *Assam musk-sacs* rarely, if ever, reach this country. Chinese musk only should be employed in medicine, and should always be purchased in sacs.

Substitutions and Adulterations.—The substitution of artificial musk-bags, made from a piece of the hide stitched to a membrane, is readily recognized by the absence of the circular arrangement of the hairs and of the central aperture. Genuine sacs are sometimes slit open, the musk partly removed, and other substances introduced in place thereof. This may usually be detected by being stitched together on the edge of the hide and inside membrane. There is no means of detecting the fraudulent introduction through the orifice of pieces of lead, etc. until after the bags have been opened.

Tests.—Musk should not have an ammoniacal odor. Cold water dissolves about one-half the weight of the musk; the solution should be deep-brown, faintly acid, and scarcely disturbed by solution of corrosive sublimate (ammonium carbonate). Weak alcohol yields a similar solution. Strong alcohol dissolves about 10 per cent., yielding a slightly colored tincture, which should scarcely become turbid on the addition of water (resins, etc.). Carefully freed from fragments of skin and hairs and heated upon platinum-foil, musk should give off a slightly urinous odor, but very distinct from the odor of burning blood, and should leave about 6 to 8 per cent. of a gray (not red) ash. The German Pharmacopœia has adopted the examination of musk by the method suggested by Bernatzik: A small quantity of musk, kept in a thin layer under oil of turpentine (or warmed with a little glycerin), and examined under the microscope, is seen to consist of diaphanous brown amorphous splinters and lumps, without being mixed with other foreign substances.

Constituents.—Musk, treated with potassa, gives off ammonia; it contains cholesterol, various fatty and waxy substances, gelatinous and albuminous compounds, and salts. The odorous principle volatilizes partly with the vapors of water, but is not a volatile oil; it is most probably formed in the presence of moisture by the slow and continuous decomposition of one of the constituents.

Off. Prep.—Tinctura moschi, *U. S.*

Allied Drugs.—*ANTILOPE DORCAS*, *Linné*. This is a deer-like ruminant inhabiting Northern Africa. Its small globular excrements have a strong musk-like odor, and have been recommended as a substitute for musk, more especially in perfumery. Jaqueme obtained from them 7 per cent. of alcoholic extract, consisting of biliary substances, of a crystallizable acid, and of an odorous resin, which is also soluble in carbon disulphide. Water dissolves ammonium and sodium salts, and the insoluble portion contains calcium phosphate.

HYRACEUM is supposed to be the dry excrements of the *khipdas* or *badger* (*Hyrax capensis*, *Curier*), a mammal of the order Hyracoidea, inhabiting Southern Africa and attaining a length of about 18 inches (45 Cm.). Hyraceum is in irregular tough but plastic pieces of a black-brown color; when warmed of a castor-like odor and having a bitter nauseous taste. It is partly soluble in water, less soluble in alcohol and ether, and when heated becomes soft, and afterward burns, giving off acrid vapors. It contains a volatile oily matter, resin, fat, various acids, biliary constituents, etc.

CIVETTA, ZIBETHUM.—Civet, *E.*; Civette, *Fr.*; Zibeth, *G.*—This is an unctuous secretion contained in a pouch located between the anus and genitals of both the males and females of *Viverra*

Civetta, *Schreber*, and *V. Zibetha*, *Schreber* (class Mammalia, ord. Carnivora). The former animal inhabits Africa, the latter Southern Asia, and they are occasionally kept captive for collecting the secretion, which is removed by means of a small ladle. It is at first yellowish, but becomes dark-brown, is fusible, nearly insoluble in water, partly soluble in ether and in hot alcohol, and has a strong musk-like odor and a bitterish, acrid, nauseous taste. It contains volatile oil, different fats, resin, coloring matters, and salts.

The above substances are sometimes, though rarely, employed as stimulants and anti-spasmodics, but are more or less used in perfumery.

Physiological Action.—Injected into the veins of animals, musk has produced a degree of narcotism with muscular spasms, followed by bloody stools, exhaustion, and death, after which cadaveric rigidity and mucous injection were found. In man it produces an effect comparable to that of alcohol, since, after stimulating the brain and heart and raising the temperature, it occasions, according to some, drowsiness and thoracic oppression, but, according to others, leaves no reactionary effects behind. Its odor continues for several days to impregnate the breath and all the secretions.

Medical Uses.—The scarcity, high price, and falsification of musk have caused its use to be comparatively restricted, and explain the varying and often contradictory estimates of its value as a medicine. Yet, on the whole, the conditions it is adapted to remedy are pretty well defined. They include all those nervous phenomena which are represented by the term *ataxia*, and among them subsultus tendinum, mild muttering delirium, floccitation, *muscae volitantes*, and hiccough, with a small, frequent, tremulous or irregular pulse, without coma and without collapse. Under these circumstances musk tends to produce refreshing sleep, while it calms muscular spasm and favors perspiration, while the pulse grows fuller, more regular, and less frequent. These are phenomena which may occur in all febrile diseases originally of a typhoid type or tending to assume it, and notably in *typhus*, *typhoid fever*, the *eruptive fevers*, and certain inflammations also, but particularly *pneumonia*. In proportion as ataxic prevail over adynamic phenomena is musk advantageous. The former are often met with in the advanced stages of *cholera infantum*, besides others that indicate serous effusion upon the brain; and they are sometimes dissipated by the administration of musk.

Its fitness to combat the special phenomena above indicated is illustrated by its efficacy in purely nervous and non-febrile affections. There can be no doubt of its having repeatedly effected a cure in cases of *hiccough*, *pharyngeal spasm*, *laryngismus stridulus*, *spasmodic croup* (spasmodic laryngitis), *spasmodic cough*, *whooping cough*, *vomiting*, and *colic*. Even *chorea*, *hysterical convulsions*, and *tetanus* have occasionally been cured by its means. Its power as a nervine is also shown by its relieving *wakefulness* resulting from combined mental and bodily fatigue—such cases, in fact, as are benefited by valerian, camphor, asafetida, and ammonia.

Musk is usually administered in pill or emulsion and in *doses* of 10 grains (Gm. 0.60) or upward, every two or three hours. It may also be employed in suppositories. To children it may be given in doses of 1 or more grains (Gm. 0.06) in the above-mentioned forms or in a small enema.

MOXA.—Moxa.

Moxa, Fr.; *Brenncylinder*, G

Moxas are vegetable substances, either cut or formed into short cylinders, and which when ignited will burn without fusing. In China and Japan moxas are made of the felt-like down covering the leaves of *Artemisia chinensis*, *Linne*, and perhaps of other plants. In other countries paper, cotton, or hemp impregnated with a weak solution of nitrate of potassium has been employed for the purpose, or the pith of some plants containing sufficient nitrates to sustain an even combustion, like that of the sunflower (see page 759). Occasionally mixtures have been made of potassium nitrate with substances like lycopodium, beaten together with some adhesive material and rolled into cylinders of convenient size. Instead of nitrate, chlorate or chromate of potassium has been employed. Cylinders made of saltpetre-paper (see page 421) have been used for the same purpose.

Medical Action and Uses.—The moxa is said to have been employed as a form of cautery from time immemorial by Oriental nations, and particularly by the Chinese and Japanese, from whom it was introduced into Europe by the Portuguese; but it was also used by the Egyptians, the Persians, and the Laplanders. The moxa cylinder should be about an inch long and from $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter. One end of it is applied to the skin and held in its place by a pair of forceps or a *porte-moxa*, while the opposite end is

lighted and the surrounding skin protected by a damp rag, a piece of adhesive plaster, or of paper saturated with a solution of alum and dried and having an aperture in its centre. Combustion is maintained by the breath or by a pair of bellows until the whole cylinder is consumed. To prevent deep cauterization liquor ammoniæ is applied immediately after the burning. Sometimes the cylinder is moved about within a small area, without permitting any one spot to become deeply involved; or it may be held very near, but without touching the skin; or, finally, it may be removed when the combustion of the moxa has reached to within a line or two of the skin. It should not usually be applied where the skin is the only covering of bone, tendon, ligament, or cartilage, nor to the mammæ, genital organs, or abdomen. The first sensation of heat is apt to be considered agreeable rather than painful, but it increases and grows tolerably severe. Yet we are assured that it causes less pain than either blisters or caustic issues.

In regard to the *modus operandi* of the moxa those who have most employed it consider that its action differs from that of the hot iron. Some have suggested that a very volatile (anæsthetic) principle is given off by the burning fibres, and in point of fact an empyreumatic oil must in this way be formed upon or near the skin; others consider that the operation is most efficient when there is really no burning of the integument or any serous or purulent discharge.

The remedial uses of moxa are those of counter-irritant agents in general. It seems to have been most efficient in affections of the superficial joints, as the *knee* and the *wrist*; in *white swelling* and *coxalgia*; in diseases of the *vertebræ* and their ligaments and in *lumbar abscess*; in *neuralgia*, and especially in *sciatica*; in *lumbago*, *rheumatic gout*, and *paralysis*; and finally in *hypertrophy of the spleen* and in *chronic bronchitis*. Of late years most of the applications of the moxa have been superseded by those of the galvanic cautery. This cautery has the advantage of being under the control of the surgeon more completely than any other, and also of being applicable to deep-seated lesions even of the bones.

MUCILAGINES.—MUCILAGES.

Mucilages, Fr.; *Schleime*, G.

These preparations consist of viscid, more or less tenacious, and adhesive liquids, or of opaque semi-liquid jellies; in all cases the solvent vehicle is water. All mucilages as directed by the pharmacopœias are prone to change, and gradually acquire an acid reaction and offensive odor, at the same time becoming more liquid. If not intended for medicinal use the change may be retarded or prevented by the addition of alum, creasote, or glycerin.

MUCILAGO ACACIÆ, U. S., Br.—MUCILAGE OF ACACIA.

Mucilago gummi arabici, P. G.—*Mucilage of gum-arabic*, E.; *Mucilage de gomme arabique*, *Mucilage arabique*, Fr.; *Gummischleim*, G.

Preparation.—Acacia, in small fragments, 34 parts (8½ oz. av.); Water a sufficient quantity; to make 100 parts (25 oz. av. or about 19 fluidounces). Wash the acacia with cold water, then add to it 66 parts (16½ oz. av. or 15½ fluidounces) of water; agitate occasionally until it is dissolved, and strain.—U. S.

Gum-arabic 4 oz. av.; distilled water 6 fluidounces (Imperial).—Br. Gum-arabic 1 part; distilled water 2 parts.—P. G. Powdered gum-arabic 1 part; cold water 1 part; dissolve in a mortar.—F. Cod.

White and clear pieces of gum-arabic should be selected for preparing this mucilage. The impurities which necessitate the subsequent straining are generally accidental admixtures of the gum, and may mostly be removed by rapid washing with cold water before dissolving it. The solution may be effected in a corked bottle by placing it on its side, whereby a more extended surface of the gum is exposed to the solvent action of water, and by agitating it occasionally so as to mix the heavy solution with the lighter liquid. It is a nearly transparent, colorless, or scarcely yellowish, viscid liquid, having a faint rather agreeable odor and an insipid taste. To prevent its decomposition, Archer & Co. (1874) employed *tolu-water* instead of distilled water, using 1 fluidrachm of tincture of tolu, rubbed up with carbonate of magnesium, to 1 pint of water.

Pharmaceutical Uses.—This mucilage serves for the suspension of insoluble

substances in mixtures and to impart adhesiveness to pill masses. The British Pharmacopœia directs it to be used as an excipient in the preparation of troches.

MISTURA GUMMOSA.—Gum mixture, *E.*; Potion gommeuse, Julep gommeux, *Fr.*; Gummimixtur, *G.*—Powdered gum 10 parts, syrup of gum 30 parts, water 100 parts, and orange-flower water 10 parts.—*F. Cod.*

Off. Prep.—Syrupus acaciæ, *U. S.*

Medical Uses.—This mucilage, diluted according to the taste or the condition of the patient, and sweetened and flavored, forms a customary drink in *fevers* and in inflammatory affections of the *respiratory* and *digestive* organs. It is probably not directly nutritive, but it possibly retards tissue-waste.

MUCILAGO AMYLI, *Br.*—MUCILAGE OF STARCH.

Mucilage d'amidon, *Fr.*; *Stärkeschleim*, *G.*

Preparation.—Take of Starch 120 grains; Distilled Water 10 fluidounces. Triturate the starch with the water gradually added, then boil for a few minutes, constantly stirring.—*Br.*

It should always be made fresh when needed.

Off. Prep.—Enema aloes. Enema magnes. sulphat., Enema opii, Enema terebinthinæ, *Br.*

Medical Uses.—Mucilage of starch is generally entrusted to domestic manufacture, but it may be worth while for physicians to know that 120 grains of starch should be mixed with about $\frac{1}{2}$ pint of water (Gm. 4 to Gm. 250) to procure a liquid of the proper density for an enema, such as may be used in *dysentery*. But in that disease, if opiates or any other medicines intended to be retained are to be added to the mucilage, the quantity of it injected should not exceed 3 ounces.

MUCILAGO CYDONII, *U. S.*—MUCILAGE OF CYDONIUM.

Mucilage cydoniæ.—*Mucilage of quince-seed*, *E.*; *Mucilage de coing*, *Fr.*; *Quittenschleim*, *G.*

Preparation.—Cydonium 2 parts (18 grains or 1.2 Gm.); Distilled Water 100 parts (900 grains or 60 Gm. or 2 fluidounces). Macerate the cydonium for 30 minutes in a covered vessel with the distilled water, frequently agitating. Then strain the liquid through muslin, without pressure. This preparation should be freshly made when required for use.—*U. S.*

The P. G. 1872 recognized the same formula, but employed rose-water. The French Codex directs quince-seed 1 part and tepid water 50 parts, to be left in contact for 6 hours, after which the mucilage is strained with pressure.

Bandolin is a mucilage of quince-seeds used for dressing the hair, and is made by macerating 2 drachms of unbroken quince-seeds in a pint of water, and adding about an ounce of cologne-water, with some other scent to suit.

Action and Uses.—Quince-seed mucilage is lenitive and protective, and, like other mucilages, may be applied to the *inflamed skin* or *conjunctivæ*, and may be administered internally in *gastro-intestinal* and *urinary inflammations*, and to allay *cough*, irritation of the air-passages, etc.

MUCILAGO SASSAFRAS MEDULLÆ, *U. S.*—MUCILAGE OF SASSAFRAS-PITH.

Mucilage de moëlle de sassafras, *Fr.*; *Sassafrasmark-Schleim*, *G.*

Preparation.—Take of Sassafras-Pith 2 parts (9 grains); Water 100 parts (450 grains or 1 fluidounce). Macerate for 3 hours, and strain.—*U. S.*

It is a colorless, thickish, transparent liquid of a bland taste.

Medical Uses.—The mucilage of sassafras-pith is a refreshing and useful application to the eye in *acute conjunctivitis*, and may serve as a vehicle for more active agents. It is equally appropriate as a soothing lotion in erythematous and other *inflammations of the skin*. Internally, it may be freely used as a drink in *dysentery* and other bowel complaints, and in *febrile affections* generally.

MUCILAGO TRAGACANTHÆ, U. S., Br.—MUCILAGE OF TRAGACANTH.

Mucilage de gomme adragante, Mucilage adragant, Fr.; Traganthschleim, G.

Preparation.—Tragacanth 6 parts (144 grains); Glycerin 18 parts (432 grains = 6 fluidrachms); Water a sufficient quantity; to make 100 parts (2400 grains or 5½ oz. av.). Mix the glycerin with 76 parts (1824 grains or 4 fluidounces) of water; heat the mixture to boiling, add the tragacanth, and let it macerate for 24 hours, stirring occasionally. Then add enough water to make the mixture weigh 100 parts (5½ oz. av.), heat it so as to render it of uniform consistence, and strain forcibly through muslin.—*U. S.*

Take of tragacanth, in powder, 60 grains (or 12 parts); distilled water 10 fluidounces (or 875 fluid parts); rectified spirit 2 fluidrachms (or 22 fluid parts). Mix the tragacanth with the spirit; then pour in the water with constant agitation.—*Br.*

The first formula yields a thick jelly-like mass, the second a more fluid preparation. The former is better adapted as an excipient for troches (*U. S.*) and many pill masses. If made without glycerin, as directed by the *U. S. P.* 1870 and by the French Codex (tragacanth 1 part, water 9 parts), it has the disadvantage of drying out and rendering the pills very slowly soluble—a fault which has been corrected by substituting glycerin for a portion of the water. Thus prepared, it may be readily mixed with aqueous liquids, and serves also a good purpose for suspending insoluble substances.

Medical Uses.—Tragacanth mucilage has scarcely any medicinal qualities peculiar to itself. It is seldom used unless as an excipient in lenitive mixtures, and in troches and lozenges which are intended to dissolve slowly in the mouth. Its tenacity has led to its occasional use as a protective for burns and ulcers.

MUCILAGO ULMI, U. S.—MUCILAGE OF SLIPPERY-ELM BARK.

Mucilage d'écorce d'orme fauve, Fr.; Ulmenrinden-Schleim, G.

Preparation.—Elm, sliced and dried, 6 parts (108 grains); Boiling Water 100 parts (1800 grains or 4 fluidounces). Macerate for 2 hours in a covered vessel, and strain.—*U. S.*

There is no obvious reason for specially drying slippery-elm bark: perhaps *bruised* was intended, as heretofore directed. The mucilage, becoming cold during the protracted maceration, cannot be strained without pressure, whereby a portion of the powder resulting from the ruptured tissues would be forced through the strainer. By substituting digestion for maceration the process could be materially shortened and the warm liquid more readily strained. The mucilage contains at least a portion of the starch of the bark; if intended to be free from starch, cold water should be used. (See also page 544).

Medical Uses.—As a demulcent, mucilage of slippery elm is employed in *acute* affections of the respiratory, digestive, and urinary organs. As a lenitive for external use it is frequently applied to *erysipelatous* and other *acute cutaneous eruptions, abscesses, rheumatic joints*, etc. It is very apt to grow sour, and, if allowed to get dry, renders the skin painfully hard and stiff.

MUCUNA.—COWAGE.

Setæ siliquæ hirsutæ.—Cowhage, *E*; *Pois velus, Pois à gratter, Fr.; Kratzbohnen, Kuhkrätze, G.*

The hairs of the pods of *Mucuna* (*Dolichos, Linné, Stizolobium, Persoon, Carpopagon, Roxburgh*) *pruriens, De Candolle, s. Mucuna prurita, Hooker. Woodville, Med. Bot., t. 153; Bentley and Trimen, Med. Plants, 78.*

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—This is a long, slender, twining plant, with large trifoliate, nearly smooth leaves, and showy dark-purple and greenish flowers in pendulous axillary racemes, producing flattish, hairy, S-shaped legumes, with about four brownish seeds mottled with black. It is cultivated and wild both in the East and West Indies.

Description.—The hairs covering the legumes are about ¼ inch (3 Mm.) long, of a glossy-brown color, straight, quadrangular prismatic, sharply pointed at the apex, somewhat retrorsely serrate on the upper half, and partly empty, partly filled with a brown granular matter. They easily penetrate the skin, and occasion an intolerable itching, which is greatly increased by washing and rubbing.

The fruits of *Stizolobium* (*Mucuna, De Candolle, Dolichos, Linné*) *urens, Persoon*, are

shorter, less bent, and covered with shorter and darker hairs, which are used like the preceding. An emulsion of the seeds is used in the West Indies in dysuria, and an infusion of the root of the first species is considered to possess diuretic properties, and in India is employed as a remedy in cholera.

Constituents.—Nothing is known of the composition of cowhage, except that it contains a little tannin and resin (Martius, 1827).

Medical Action and Uses.—Cowhage was originally employed as a *vermifuge* under the idea that its prickly setæ, which irritate the skin so severely and are so difficult to detach, would wound and injure the worms, and either kill them or promote their expulsion. Observation showed, however, that when the spiculæ are moistened they are quite innocuous, and there is much reason for believing that the supposed vermicide virtues of this substance are imaginary. It is difficult to imagine that an agent which has actually been employed to produce a painful irritation and eruption upon *paralyzed limbs* for the purpose of arousing their dormant functions should cripple or destroy intestinal worms and leave the intestine itself uninjured. As a vermifuge the setæ are mixed with honey or molasses by dipping the pods in the liquid, and when it has reached the consistence of an electuary it may be given, fasting, in doses of 1 or more teaspoonfuls for several successive days. Subsequently a purge of calomel and jalap may be prescribed; and this is, doubtless, the most efficient part of the treatment. When formerly used to relieve paralysis, it was applied in a layer upon the affected part, supported by thin paper or a similar substance, or else incorporated in simple ointment or lard.

MYRICA.—WAX-MYRTLE.

Bayberry, Candleberry, E.; Arbre à suif, Fr.; Wachsbäum, Wachsgagel, G.

Myrica cerifera, Linné.

Nat. Ord.—Myricaceæ.

Origin.—The wax-myrtle is shrubby or sometimes arborescent, usually from 4 to 8 feet (1.2–2.4 M.) high, and grows near Lake Erie, but chiefly along the Atlantic coast of North America. It has alternate, oblong-lanceolate, entire or near the apex sparingly toothed leaves, which are nearly smooth, about 2 inches (5 Cm.) long, on both sides covered with resinous dots, and fragrant when bruised. The flowers are diœcious, the staminate ones in nearly cylindrical catkins about $\frac{3}{4}$ inch (18 Mm.) long, the pistillate ones shorter, and producing globular one-seeded nuts, which are of the size of a pea, blackish, and covered with a white waxy incrustation.

The bark and waxy incrustation of the fruit have been employed.

Description.—1. The bark is in quills or curved pieces about $\frac{1}{16}$ inch (1.5 Mm.) thick, externally covered with a whitish, slightly wrinkled, thin, corky layer, which separates in small fragments, underneath which the bark is dark reddish-brown and nearly smooth, resembling the inner surface, except that the latter is slightly striate. The fracture is granular, of a pale-reddish color, and scarcely fibrous in the inner layer. The bark yields a light reddish-brown irritating powder, which has a peculiar aromatic odor and an astringent somewhat bitter and pungently acrid taste.

2. Myrtle-wax, or *bayberry tallow*, is prepared by boiling the fruit with water until the fat collects on the surface. It has a balsamic odor, is harder and more brittle than beeswax, varies in color between green, yellowish, and gray, and breaks with a shallow conchoidal fracture. G. E. Moore (1862) found its specific gravity to range from 1.004 to 1.006, its fusing-point from 47° to 49° C. (116.6° to 120.2° F.), and four-fifths of it to be soluble in hot alcohol.

Constituents.—The constituents of bayberry-bark, as determined by G. M. Ham-bright (1863), are, besides those more generally met with, a trace of volatile oil, tannin, an acrid resin soluble in alcohol and ether, an astringent resin insoluble in ether, and *myricinic acid*, the latter obtained from the alcoholic extract, after having been treated with ether, by exhausting it with hot absolute alcohol. It forms small granules, which produce a thick froth on being agitated with water, and on the addition of ammonia a deep-green color, rapidly changing to red and yellow. It has a lastingly acrid taste. Dana obtained from the fruit 32 per cent. of solid fat, 5 of resin, and 45 of starch. The myrtle-wax consists, according to G. E. Moore, of about one-fifth palmitin, the remainder being palmitic acid, with a small quantity of lauric acid.

Allied Plants.—*Myrica Gale, Linné.*—Sweet gale, Dutch myrtle, *E.*: Piment royal, Galé odorant, *Fr.*: Gagel, Brabanter Myrte, *G.*—This is a smaller shrub than the preceding, growing in swampy places from the mountains of North Carolina northward to Canada, and in the northern

parts of Europe and Asia. The leaves are on short petioles $1\frac{1}{2}$ inches (38 Mm.) long, obovate-lanceolate, wedge-shaped at the base, serrate near the apex, subcoriaceous, softly pubescent beneath, and on both sides with yellow resinous dots. The fruit is likewise resinous-dotted. The leaves and brown branches have a strong balsamic odor and an aromatic, astringent, and bitterish taste. Rabenhorst (1836) obtained from 3000 parts of fresh leaves 1 part of a thickish volatile oil containing 70 per cent. of stearopten.

A solid fat very similar to myrtle-wax is obtained from the fruit of other species of *Myrica* indigenous to different countries.

Medical Action and Uses.—The bark of the root is acrid and stimulant, and in doses of a drachm causes a sensation of heat in the stomach, followed by vomiting, and sometimes by diuresis. When chewed it acts as a sialagogue, and has proved useful in *toothache*. The powder is an active errhine. The leaves have some celebrity in domestic practice as an anti-spasmodic, anti-scorbutic, and astringent medicine. They have been used to check *hæmoptysis*. The other native species are very similar in their properties. The "myrtle-wax" which covers the berries appears to have astringent and slightly narcotic properties, and was used with alleged success in an epidemic of typhoid *dysentery* when it was administered in the dose of 1 or 2 drachms (Griffith).

MYRISTICA, U. S., Br.—NUTMEG.

Semen myristicæ, P. G. ; *Nux moschata*.—*Muscade*, *Noix de muscade*, Fr. ; *Muskatnuss*, G.

The kernel of the seed of *Myristica fragrans*, *Houttuyn*, s. *M. moschata*, *Thunberg*, *M. aromatica*, *Lamarck*, *M. officinalis*, *Linneé filius*. Suppl. Steph. and Church, *Med. Bot.*, plate 104 ; Bentley and Trimen, *Med. Plants*, 218.

Nat. Ord.—Myristicaceæ.

Origin.—The nutmeg tree is indigenous to the Molucca Islands, but is at present cultivated in various parts of India, in the Philippines, West Indies, and South America. It attains a height of 30 to 60 feet (9–18 M.), and has alternate, smooth, entire, and prominently veined, leathery leaves, and small, yellowish, dioecious flowers, with the stamens united into a fleshy column, and a superior ovary, ripening into a dehiscent, pear-shaped, tough, one-seeded berry. The tree commences to yield fruit when about nine years old, and continues productive for sixty or seventy years.

Collection.—The fruit is gathered, when split on one side, by means of a long hook fastened to a long stick ; the pericarp is removed, and the arillus (see *MACIS*, p. 943)

FIG. 189.

Nutmeg with mace, and transverse section.

detached from the nut-like seed, which on the Banda Islands is carefully dried first by solar heat for a few days, or in Bencoolen at once on frames over a slow wood-fire at a temperature of about 140° F. This requires about 2 months, during which time the seeds are frequently turned, and when the kernels rattle in the shell they are packed for the Chinese market. The entire seeds do not enter the European and American commerce, but only the kernels, which are removed from the shell by cracking the latter with a wooden mallet, carefully garbled and packed (*unlimed nutmegs*), sometimes mixed with cloves, in casks which have been smoked and whitewashed on the inside. In the Dutch colonies the kernels are dipped in a thick milk of lime (*limed nutmegs*)—a custom which originated in the desire to destroy the vitality of the embryo, and thus limit this culture to their own possessions. Small and worm-eaten nutmegs are usually used for obtaining the fixed oil. About 1,000,000 pounds of nutmegs are now annually consumed in the United States.

Description.—Nutmeg in the shell is an oval or elliptical seed about an inch (25 Mm.) or more in length, with a brown, somewhat glossy, woody but brittle testa, light-brown raphe, and bearing the shallow impression of the mace. The nutmegs of our commerce are deprived of the testa or shell, oval or ovate in shape, an inch (25 Mm.) or a little less in length, and marked on the broad end with a circular scar, from which proceeds a shallow furrow to a deeper depression near the upper end. The entire surface is reticulately furrowed and of a light-brown color, or covered, particularly in the furrows, with a white powder (lime). The embryo is located near the broad end in a small conical cavity of the albumen or endosperm, which constitutes the remainder of the commercial article, is of a pale brownish-yellow color, has a fatty lustre, and is dissected by numerous curved channels filled with brown tissue and penetrated by the inner seed-coat (tegmen). Nut-

nuts have a strong and pleasant aromatic odor and a warm, aromatic, somewhat bitter taste.

The Penang and Singapore nutmegs are unlined; the Dutch are lined.

False Nutmegs.—The *long, wild, or male* nutmeg resembles the foregoing, but is oblong, about $1\frac{1}{2}$ to 2 inches (4–5 Cm.) long; the mace inodorous, less deeply lobed, the kernel of a paler color than nutmeg, and scarcely aromatic. It is obtained from *Myristica fatua*, *Houttuyn*, and is rarely seen in our commerce.

The so-called *California nutmeg* is the seed of *Torreya californica*, *Torreya*, s. T. *Myristica*, *Hooker*; nat. ord. Coniferae, sub-ord. Taxineae. It is oblong, with a smooth, brownish, thin testa, enclosing a kernel of the same shape, which has upon cross-section a marbled appearance similar to that of the nutmeg, but has a terebinthinate odor and taste. The tree grows to the height of 70 feet (21 M.), and has an odorous light-colored and close-grained wood.

Constituents.—Nutmegs contain between 2 and 8 per cent. of volatile oil (see OLEUM MYRISTICÆ), between 25 and 30 per cent. of fat (see OLEUM MYRISTICÆ EXPRESSUM), some starch, protein compounds, and other principles of no medicinal importance.

Off. Prep.—Acetum opii, Pulv. aromaticus, *U. S.*; Pulv. catechu comp., Pulv. cretæ aromaticus, Spiritus armoraciæ comp., *Br.*; Tinctura lavandulæ comp., *U. S., Br.*; Tinct. rhei arom., Trochisci cretæ, Troch. magnesiæ, Troch. sodii bicarbonatis, *U. S.*

Medical Action and Uses.—Observations and experiments upon man and animals agree in showing that nutmeg has a narcotic and intoxicating power. A woman took $\frac{1}{2}$ pint of whisky in which an ounce of finely-powdered nutmeg was mixed. She suffered various symptoms, probably due to the alcohol in the draught. It is stated that after these subsided she had pain in the ovaries, a leucorrhœal discharge, and sexual excitement (*Phila. Med. Times*, x. 438). It is but little used as a medicine, except for flavoring purposes, but extensively as a condiment to qualify the action of oleraceous vegetables, soups, and pastry. It may be given in cases of simple debility of the stomach in doses of from 5 to 20 grains (Gm. 0.30–1.30).

Wild Nutmeg, with mace.

MYROBALANUS.—MYROBALAN.

Myrobalans, E., Fr.; *Myrobalanen*, G.

The fruit of several species of *Terminalia*, *Linné* (*Myrobalanus*, *Gaertner*).

Nat. Ord.—Combretaceæ.

Origin.—The following species yield myrobalans: *Terminalia Chebula*, *Retzius*, *T. bellerica*, *Roxburgh*, *T. citrina*, *Roxburgh*, and perhaps others. They are large trees, indigenous to India, with coriaceous entire and alternate or nearly opposite leaves, decandrous whitish or yellowish racemose flowers, and one-seeded drupaceous fruits.

Description.—The following varieties have been distinguished:

1. *MYROBALANI CHEBULÆ*. They are $1\frac{1}{2}$ to 2 inches (3–5 Cm.) long and $\frac{1}{2}$ to 1 inch (12–25 Mm.) thick, oblong or pyriform in shape, obtusely five-angled and five-ribbed, blackish-brown, the endocarp pale-brown and resinous-dotted, and contain a white seed.

2. *M. BELLERICÆ*. They are roundish-oval, of about the size of a nutmeg, narrowed below, and indistinctly five-angled, reddish-brown, covered with a soft brownish tomentum, and contain a pale-brown endocarp enclosing the ovate and obtusely triangular seed.

3. *M. CITRINÆ*. These are $1\frac{1}{2}$ inches (38 Mm.) long, oblong, obtusely five-angled, ribbed, orange- or ochre-yellow, smooth, with a pale-brown acutely angular endocarp and a cylindrical seed.

4. *M. NIGRÆ*, s. *INDICÆ*. These are unripe fruits, varying in size and shape, blackish-gray, and with an undeveloped seed.

5. *M. EMBLICÆ*. These are obtained from *Emblica officinalis*, *Gaertner*, s. *Phyllanthus Emblica*, *Linné*, a euphorbiaceous tree of India, and consist of subglobular drupaceous six-grooved capsules, which contain in each of the three cells two triangular red-brown seeds.

Constituents.—The astringent taste of myrobalans is due to tannin; *Stenhouse* (1843) found in the first variety also gallic acid, mucilage, and brown-yellow color. The last variety contains notable quantities of sugar. According to *Hennig* (1869), myrobalans yield about 45 per cent. of tannin, which is obtainable in the same manner as

from nutgalls, and at a lower price, owing to the cheapness of the drug. The seeds contain fixed oil.

Allied Species.—*Terminalia catappa*, *Linne*. The bark is very astringent. The seeds resemble almonds, are edible, and yield about 30 per cent. of a bland fixed oil, which does not readily turn rancid, and at 5° C. (41° F.) commences to separate stearin.

Term. benzoin, *Linne filius*, s. *T. augustifolia*, *Jacquin*. The resinous exudation is fragrant and resembles benzoin in properties.

Medical Action and Uses.—These fruits are now wholly disused in medicine, although they were once held in high esteem. Pliny speaks of one species as an astringent in diarrhoea and menorrhagia and as a vulnerary. The Arabian physicians abound in their praise. Some species appear to have been cholagogue and others astringent. Rhazes declares that they act as emetics and cathartics, purge away the excrement, remove humidity, strengthen the senses and the understanding, and are useful in cutaneous eruptions, colic, mental debility, obstinate fevers, headache, dropsy, and splenic disorders. Mesue embellishes this statement by adding, among other things, "that they restore youth, improve the complexion, the breath, and the perspiration, impart joy and hilarity," etc. They continued to be used by European physicians as late as the last century.

MYRRHA, U. S., Br., P. G.—MYRRH.

Gummi-resina myrrha.—*Myrrhe*, Fr., G.

A gum-resinous exudation from *Balsamodendron* (*Balsamea*, *Engler*) *Myrrha*, *Nees*. *Plant. Med.*, plate 357; Berg and Schmidt, *Off. Gew.*, t. 29; Bentley and Trimen. *Med. Plants*, 59.

Nat. Ord.—*Burseraceæ*.

Origin.—Myrrh exudes spontaneously from large shrubs or small trees, about 10 feet (3 M.) high, growing in the Somali country and in South-western Arabia, and is collected by the Somalis, who cross the Gulf of Aden for the purpose; but the principal supply of myrrh comes from Eastern Africa, from the country of the Somalis. The plant was collected by Ehrenberg (1820–26) in Arabia, and a second species found in Africa was subsequently named *Bals. Ehrenbergianum*, *Berg*, but is by Oliver and Bentley considered identical with *B. Opobalsamum*, *Kunth*, which grows northward into Abyssinia, and is the source of balm of Gilead (see below). Formerly, myrrh entered commerce through Egypt and the ports of the Levant, hence the term *Turkey myrrh*; at present it is mostly taken from Aden and Berbera to Bombay, where it is assorted before being shipped to Europe and America. From the observations of Marchand (1866), it seems to be chiefly produced in the bark and to a small extent in the pith. About 20,000 pounds of myrrh are imported into the United States.

Description.—Myrrh is in roundish or irregular tears, or in larger masses having an uneven surface of a lighter or darker reddish-brown color and dull dusty appearance. These break readily with an uneven somewhat splintery fracture, which is of a waxy lustre, apparently fatty to the touch, often marked with semicircular whitish lines of a brownish-yellow or reddish color, and translucent, at least when in thin layers. In cold weather myrrh may be readily powdered, but in warm weather it cannot be reduced to a fine powder until after it has been well dried and deprived of some volatile oil. When triturated with water it yields a brown-yellow emulsion. Alcohol dissolves it partly, leaving the gum behind and yielding a brownish orange-colored tincture. The alcoholic extract dissolved in ether acquires a red or violet color in the presence of bromine vapor. Myrrh has a peculiar rather agreeable odor and an aromatic, acrid, and bitter taste.

Other Varieties of Myrrh.—According to Vaughan (1853), there are two other varieties of myrrh found in the Arabian commerce at Aden—one called by the Arabs *muc.* or by the Somalis *mulmul*, also known as *heera bôl*, by which names African myrrh is likewise known; it resembles the latter in all sensible properties, and is considered identical with it, although it is usually upon the fractured surface destitute of the whitish lines and dissolves in alcohol, sometimes to the extent of 25 per cent. The other variety is known as *bissa bôl*, or by the Somalis as *hebbakhade*. Hanbury (1853) states that it is the *Myrrha indica* of Martiny, and was formerly, but is not now, distinguished in commerce as *Indian myrrh*; it has the appearance of an inferior dark-colored myrrh, and is chiefly distinguishable by its different odor, which is likened to that of mushrooms.

Admixtures.—Myrrh is not unfrequently mixed with dark-colored pieces of various

gums, some of which merely swell with water, and with *East India bdellium*. The latter is referred to *Balsamodendron* (*Balsamea*, *Engler*) *Mukul*, *Hooker*, and, according to Dymock (1876), a similar exudation is yielded by *B. Roxburghii*, both species indigenous to India, but perhaps also growing in Southern Arabia. It is in large pieces, rounded and dusty on the surface, breaks with a flat conchoidal fracture, has a dark sometimes blackish-brown color, is translucent in thin layers, and has an odor somewhat resembling myrrh; its tincture does not acquire a purplish color on the addition of nitric acid.

Constituents and Tests.—Myrrh contains a small quantity of volatile oil which may reach 2 or $2\frac{1}{2}$ per cent., from 25 to 40 per cent. of resin, 40 to 65 (or in Arabian myrrh 75) per cent. of gum, and yields about $3\frac{1}{2}$ per cent. of ash, mostly CaCO_3 . *Oil of myrrh* is a pale-yellow, thick liquid, of specific gravity 0.98, but, according to Brandes (1819), sometimes heavier than water. The variable yield is explained by Bley and Diesel (1845) by oxidation, whereby, among other products, formic acid is formed. From the same cause, probably, the composition may vary: Ruickholdt (1845) obtained results leading to the formula $\text{C}_{10}\text{H}_{14}\text{O}$, which would make it isomeric with thymol and earyol; Heldt (1847) found $\text{C}_{22}\text{H}_{32}\text{O}_2$; Buri (*Pharmacographia*) obtained $\text{C}_{22}\text{H}_{32}\text{O}$. Dissolved in bisulphide of carbon, the oil gradually assumes a permanent violet or blue color after the addition of nitric acid or bromine. The *resin* is entirely soluble in alcohol, ether, and chloroform. Hager (1865) found it only partly soluble in bisulphide of carbon, the soluble portion acquiring a violet color with nitric acid and with bromine. Hydrochloric acid produces the same color with the resin, after previously moistening it with alcohol. The bitter principle, according to Flückiger, is sparingly soluble in water, partly soluble in carbon disulphide, soluble in ether and in alcohol, and from the latter solution precipitated by lead acetate; its alkaline solution reduces Fehling's test liquid and precipitates floccules on the addition of acids. The *gum* consists, according to Hekemeijer (1858), of two kinds—one being precipitated by neutral, the other by basic acetate of lead. Shuttleworth (1871) recommends it as making a good paste of unlimited keeping qualities; its adhesiveness is increased by the addition of a little molasses. Myrrh melts together with caustic potassa with some difficulty; Hlasiwetz and Barth (1866) found among the products protocatechuic acid and a little pyrocatechin.

Allied Drugs.—*BALSAMUM GILEADENSE*, *Balm of Gilead*, *Mecca balsam*, or *Opobalsamum*, though differing greatly from myrrh, is referred to *Balsamodendron Opobalsamum*, *Kunth*. It is said to exude spontaneously, and is an opaque yellowish or whitish, fragrant, viscid liquid, in which Trommsdorff found 30 per cent. of volatile oil and 64 per cent. of hard resin, while Bonastre obtained only 10 per cent. of volatile oil, 70 per cent. of adhesive, and 12 of hard resin. It is at present rarely, if ever, met with in our commerce.

BDELLIUM. Indian bdellium is described above. African bdellium is the exudation of *Balsamodendron* (*Balsamea*, *Engler*; *Heudelotia*, *Richard*) *africanum*, *Arnott*, a shrub indigenous to West Africa, and is used in France chiefly as an addition to some plasters. It is met with in irregular roundish or oval tears about an inch (25 Mm.) in diameter, and varying in color from pale-yellowish to brown-red. It is translucent, breaks with a waxy fracture, and resembles myrrh in odor and taste, but its tincture does not become purple on the addition of nitric acid.

Pharmaceutical Preparation.—*EXTRACTUM MYRRHÆ*, Extract of myrrh, made with cold distilled water, contains chiefly gummy matter and the bitter principle.

Off. Prep.—Decoet. aloes comp., *Br.*; Mistura ferri comp., Pilulæ aloes et myrrhæ, *U. S.*, *Br.*; Pil. ferri comp., *U. S.*; Pil. galbani (assafetidæ) comp., Pil. rhei comp., Tinct. myrrhæ, *U. S.*, *Br.*; Tinct. aloes et myrrhæ, *U. S.*

Medical Action and Uses.—Myrrh is both stimulant and tonic. In small doses it appears to quicken the appetite and digestion; in larger doses it irritates the stomach, occasioning nausea, and even vomiting and diarrhœa, quickening the pulse, stimulating the bronchial mucous membrane, and probably exerting a special influence of the same sort upon the uterine system. It has been found useful in *atonic dyspepsia* with flatulence, mucous evacuations, constipation, and associated nervous disorders of an hysterical or hypochondriacal description. In such affections it is profitably combined with vegetable bitters and iron. The compound iron mixture is a valuable preparation of this nature which is extensively employed in *amenorrhœa* connected with anæmia and general torpor of the functions. In like manner it may be employed in chronic uterine and vaginal *leucorrhœa*. Myrrh is especially useful in *chronic bronchitis* with profuse expectoration, but if fever is present its dose should at first be small. In ancient times it was much used as a vulnerary to promote the healing of *wounds*, *ulcers*, etc. of an indolent type. Its stimulant and astringent qualities are manifested in cases of *spongy and ulcer-*

ated gums. Its dose is from 5 to 30 grains (Gm. 0.30–2), but it is seldom used in substance. It may be prescribed in emulsion as an enema.

MYRTUS.—MYRTLE.

Myrté, Fr., G.

Myrtus communis, Linné.

Nat. Ord.—Myrtaceæ.

Origin and Description.—The myrtle is a shrub or small tree inhabiting the countries near the Mediterranean, and frequently cultivated. It has a dark grayish-brown, fissured, astringent bark, and opposite, smooth and glossy, entire leaves, varying in length from $\frac{1}{2}$ inch to 2 inches (12–50 Mm.), and in shape from ovate to linear-lanceolate and mucronate; they are on very short petioles, are densely pellucid-punctate, and bear in their axils a white or light-pinkish flower with numerous stamens. The fruit is a roundish-oval or subglobular, fleshy, bluish-black berry of the size of a pea, with two cells, each containing four or five whitish kidney-shaped seeds. The leaves, flowers, and fruit have a very agreeable odor.

Constituents.—Riegel (1849) obtained from the ripe berries volatile oil, resin, tannin, citric acid, malic acid, sugar, etc. Raybaud (1834) found the volatile oil, as distilled from the leaves, flowers, and fruit, to have a yellowish or greenish-yellow color, and to be lighter than water. Gladstone (1863) ascertained it to have the specific gravity .891, to be dextrogyre, and to consist mostly of a hydrocarbon, $C_{10}H_{16}$, boiling between 160° and 170° C. The bitter principle has not been investigated.

The fragrant water distilled from the flowers and leaves is known in France as *eau d'ange*.

Allied Plants.—MYRTUS CHERAN, Sprengel, s. EUGENIA CHEREN, Molina, is a shrub about 5 feet (1.5 M.) high, with a rough brown astringent bark, and indigenous to Chili, where it is known as *cheken*, *chekan*, or *chequen*. The leaves are collected with the brown-gray branches, and are nearly sessile, about $\frac{1}{3}$ inch (2 Cm.) long, oval-lanceolate or elliptic, somewhat revolute on the margin, rather light-green, smooth, delicately feather-veined, and dotted with minute oil-glands; they have a slight aromatic odor and an aromatic, pungent, and slightly bitter taste. C. H. Hutchinson (1879) found tannin and volatile oil, but no alkaloid. J. Höhn (1882) obtained 4.2 per cent. of tannin and indications of the presence of a glucoside. J. W. England (1883) isolated from the distillate with potassa small white crystals, which he believes to be the acetate of a volatile alkaloid, *chekenine*; this supposed salt is insoluble in ether, soluble in alcohol and water, not precipitated by iodine or by Mayer's solution, has a feeble bitter taste, and with nitric acid and potassium ferrocyanide gives a green color. The leaves yield from 2 to 4 per cent. of volatile oil and from 8 to 10 per cent. of ash. Mr. England proposed for the *fluid extract of cheken* a menstruum composed of 3 parts of alcohol and 1 part of water.

PSIDIUM PYRIFERUM, Linné, and Ps. POMIFERUM, Linné, are small trees of the West Indies and other tropical countries, having an astringent bark, aromatic and astringent leaves, and fragrant flowers. The acidulous fruit is known as *guava*, and is used in the form of jelly, marmalade, etc.

JAMBOSA VULGARIS, De Candolle (Eugenia Jambos, Linné), and J. MALACCENSIS, De Candolle, are larger East Indian trees, of which the flowers, leaves, and bark are employed. The fruit, known as *rose-apple*, has an acidulous rose-like flavor.

Medical History and Uses.—The myrtle, so renowned in history and poetry, was hardly less distinguished for its medicinal virtues. It occupies a prominent place in the writings of Hippocrates, Pliny, Dioscorides, Galen, and the Arabian writers. Pliny furnishes an account of it of which the following is a summary: The berries arrest hæmoptœ: they are used in dysentery and as an application to indolent ulcers and inflamed eyes; and in wine are an antidote to the poison of mushrooms; they also cure the bites of scorpions, inflammation of the bladder, headaches, abscesses, aphthæ, leucorrhœa, and other mucous discharges. The juice is diuretic, but constipates. An ointment made with it cures eruptions of the skin and darkens the hair. The dried leaves in powder arrest sweats; in fomentations check the white flux, correct prolapsus of the womb and rectum, and are employed to cure ulcers, burns, erysipelas, otorrhœa, alopecia, and eruptions of the skin, to arrest hæmorrhage, and as an application to lentigo, pterygion, panaris, condylomata, and swelled testicles. A wine made from the berries was used for most of these purposes, and was regarded as tonic. This catalogue of virtues is repeated, but hardly enlarged, by subsequent ancient writers, who, however, following Galen, ascribe to myrtle the opposite qualities of cold and hot or astringent and stimulant, the former reserved chiefly in the leaves, the latter in the berries.

It is remarkable that a plant which was formerly used for so many medicinal purposes

should have become almost obsolete as a medicine. In 1876 attention was directed toward it by Delioux de Savignac, from whose essay the following particulars are taken: He used the infusion of the leaves or a dilution of the tincture as an injection in *leucorrhœa* and *prolapsus of the uterus*. Its agreeable odor renders it more acceptable than other analogous preparations to delicate women, and, besides arresting the discharge, it renders firm the parts to which it is applied. A fine powder prepared with the dried leaves was applied on tampons of cotton wadding with excellent results in cases of *ulcers of the uterus*, especially when the cotton was previously moistened with glycerin. The same powder was used with striking advantage as a dressing for recent and suppurating *wounds* and *ulcers*, for *eczema* and *intertrigo*, and was confined by carded cotton and a bandage. The infusion of the fruit or of the leaves was found equally efficacious in similar cases, and as a lotion for sinuses and other ulcers not readily accessible to the powder. Where fetid discharges or a tendency to *gangrene* existed, myrtle wine was used to destroy the fetor and promote granulation and the cure. It was also injected with excellent results into deep, suppurating sinuses. The essential oil and its alcoholic solution appear not to possess to an equal degree the anæsthetic properties of oil of peppermint, etc., but they nevertheless are somewhat anodyne.

In catarrhal affections of the *kidneys* and *bladder* powder of myrtle-leaves is recommended in doses of from 15 to 60 grains a day (Gm. 1-4); and the same prescription is stated to lessen the colliquative *sweats* of phthisis. The infusion would be more suitable in such cases, but its taste is repugnant to most patients. It is more applicable to the treatment of *dysentery* by enema. The powder, given to the extent of from 15 to 30 grains (Gm. 1-2) a day, was used with great benefit in *menorrhagia*. The author whom we cite recommends the infusion as a collyrium in *conjunctivitis*, as a gargle in various forms of *pharyngitis*, and to be used like rhatany in the treatment of *hæmorrhoids*. For the last-mentioned purpose he also found it remarkably useful when given internally with Venice turpentine in a bolus. Finally, the infusion was of service in *chronic bronchitis*. The essential oil is, however, more efficient.

An infusion of myrtle for topical use may be prepared with from 2 to 4 drachms of the leaves (Gm. 8-16) to a pint of water; for internal administration it should be diluted. An infusion of the berries may be made with similar proportions for internal as well as external administration. The finely-powdered and sifted leaves may be prescribed in doses of from 15 to 30 grains a day (Gm. 1-2). An infusion of the bark may be prepared with from 1 to 2 ounces (Gm. 32-64) in half a pint (Gm. 250) of water. The essential oil has also been used in the catarrhal affections above mentioned. It is best administered in capsules containing 4 or 5 drops of the oil.

Cheken, or *chequen*, is represented by Murrell (*Practitioner*, xxiv. 321) to be an efficacious remedy for mucous profluvia of the *air-passages* and the *urinary tract*. A fluid extract of it was given in *doses* of a teaspoonful three or four times a day. These statements have failed of confirmation by Gottheil (*Med. Record*, xxiv. 258).

NAPHTHALINUM.—NAPHTHALIN.

Naphthalene, E.; *Naphthaline*, *Naphtalène*, Fr.; *Naphtalen*, G.

Formula $C_{10}H_8$. Molecular weight 128.

Origin.—Naphthalin was discovered by Garden (1820) in coal-tar oil, and recognized by Reichenbach as resulting from the decomposition of the products of distillation of coal. It has since been obtained from a large number of organic bodies, particularly if the distillation-products are conducted through a red-hot tube, and is a constituent of the petroleum of Burmah.

Preparation.—Coal-tar oil is distilled, and that portion collected by itself which passes over between 170° and 200° C. (338° and 392° F.), or the distillation is continued until the contents of the retort begin to char. The dark-colored product is purified by resubliming it two or three times.

Properties.—Naphthalin forms colorless and transparent, glossy scales or large laminae, which have a faint and peculiar odor; from its solution in ether it crystallizes in rhombic plates or prisms. Its specific gravity is 1.15. According to Kopp (1855), it fuses at 79.2° C. (174.6° F.), forming a colorless liquid, and crystallizes again on cooling. It volatilizes slowly at the ordinary temperature, and boils at 218° C. (424.4° F.). When heated in the air its vapors are ignited with difficulty, and burn rapidly with a red and sooty flame. It is insoluble in water and alkaline liquors, freely soluble in hot alcohol, in ether, disulphide of carbon, chloroform, and in warm fixed and volatile oils. On dis-

solving together with picric acid in hot alcohol the two compounds unite, forming on cooling golden-yellow needles having the composition $C_{10}H_8.C_6H_3(NO_2)_3O$, and yielding all the picric acid to ammonia. Naphthalin yields with chlorine and bromine numerous products of addition and substitution. When treated with strong nitric acid, *nitronaphthalins* are generated, which by the action of reducing agents are converted into *naphthylamine*, $C_{10}H_7.NH_2$, which is crystallizable, turns red in the air, and the salts of which yield blue, and finally purple-colored, precipitates with ferric chloride, chromic acid, and other oxidizing agents. Commercial naphthalin usually contains a small proportion of empyreumatic oil, which causes it to assume a yellow color on exposure and to dissolve in sulphuric acid with a brown color; the impurity may be removed by recrystallization.

Medical Action and Uses.—Applied to the tongue, it gradually develops a strong, acrid, burning taste in the mouth and throat and the expectoration of rosy or frothy sputa (Dupasquier, 1842–43). It has been employed with reputed advantage in *chronic bronchitis* and *bronchorrhœa*, particularly as they occur in advanced life. In other words, its operation in these affections is the same as that of terebinthinate and balsamic medicines. Fischer (*Times and Gazette*, Dec. 1881, p. 718) was one of the first to state that naphthalin is a powerful antiseptic, preventing putrefaction and correcting the putrid exhalations from *wounds*, *ulcers*, and mucous canals, while it does not irritate the exposed tissues or excite eczema in the surrounding skin. It stains neither the skin nor the linen, and is said to have no unpleasant smell of its own, but after remaining for a while upon the skin it exhales a peculiar, but not a very strong, odor. Continued application of it to raw surfaces or to mucous membranes, or to the skin by friction, is sometimes followed by irritation in the urinary passages, and even by hæmaturia (Fürbringer, *Bull. de thérap.*, ciii. 47). Djankonow states that a solution of 1 part of naphthalin in 4 parts each of alcohol and ether, when applied to foul and indolent ulcers and wounds, causes them to granulate and cicatrize rapidly (*Amer. Jour. of Med. Sci.*, Jan. 1883, p. 247). The disease in which naphthalin has been found most useful is *scabies*. Its use was first suggested by the fact that furriers employed it to protect their goods from insects. Kaposi recommends for this affection the following ointment: $\mathcal{R}$. Naphthalin 15 parts; lard 100; green soap 50; powdered chalk 10. Except in aggravated cases, a single thorough friction is declared to be sufficient for the cure. In severer cases two frictions suffice. After them the patient is made to lie between blankets for several hours (*Centralblatt f. d. gesamte Ther.*, i. 69). The same dermatologist strongly commends the use of a 5 per cent. ointment of naphthalin in *prurigo* as the most efficient remedy for that distressing affection. It certainly does not cure the disease radically, for prurigo is an outward expression of a constitutional state. In eczema, psoriasis (Emery, 1842), tinea tonsurans, and various other cutaneous diseases in which it has been employed this preparation is of very subordinate efficiency. Dissolved in alcohol, it has been applied as a substitute for tincture of camphor in *sprains*, *contusions*, etc. It is a valuable agent in preventing the ravages of moths, book-worms, etc., and has been administered internally for *intestinal worms*. The dose is from 8 to 30 grains (Gm. 0.50–2), given in some aromatic and alcoholic vehicle. An ointment is made with 25 grains of naphthalin to an ounce of lard (Gm. 1.60 to Gm. 32).

NAPHTHOL, which bears the same relation to naphthalin as phenol does to benzol, has also been used in the treatment of *scabies* and other diseases of the skin, including *psoriasis* and *chronic eczema*. It also prevents putrescence (Van Harlingen, *Am. Jour. Med. Sci.*, Oct. 1883, p. 479; Shoemaker, *Boston Med. and Surg. Jour.*, Oct. 1883, p. 440).

NARCISSUS.—DAFFODIL.

Narcisse des prés, *Porrillon*, Fr.; *Gelbe Narcisse*, G.

Narcissus Pseudonarcissus, Linné.

Nat. Ord.—Amaryllidaceæ.

Description.—Daffodil is found wild in moist and shady places in Southern Europe, and is frequently cultivated in gardens. It has an ovate, tunicated, whitish *bulb*, which is covered by brown leaf-scales and has a mucilaginous and bitter taste. The *leaves* are flat, linear, erect, a foot (30 Cm.) long, and $\frac{1}{2}$ inch (8 Mm.) broad. The *flowers* are single on the scape, nodding, large, yellow, with a top-shaped tube and a large bell-shaped cup, wavy or crisped at the margin, and equal to the six spreading divisions of the perianth; they have an unpleasant odor and a nauseous, bitter, and acrid taste.

Constituents.—The acrid and bitter principles of daffodil have not been investigated. Caventou obtained from the flowers by ether a yellow, and by alcohol a brown-

yellow, coloring matter. Jourdain (1840) gave the name *narcitin* to an emetic, probably extractive, substance, of which he obtained 37 per cent. from the bulb and 25 per cent. from the flowers; it is described as white, translucent, of a slight odor and taste, deliquescent and soluble in water, alcohol, and vinegar. He also found 6 per cent. of gum and 24 per cent. of tannin. Gerrard obtained a crystalline neutral principle and *pseudo-narcissine*, an amorphous alkaloid.

NARCISSUS JONQUILLA, *Linné, Jonquil*. The scape bears two to five small, yellow, fragrant flowers, from which ether takes up a yellow, butyraceous, volatile oil of a very agreeable odor; afterward alcohol dissolves a brown, viscid oil of an unpleasant odor (Robiquet, 1835).

Medical Action and Uses.—The several species of *Narcissus* appear to possess almost identical qualities. Pliny describes their emetic, purgative, maturative, and cicatrizing powers, and refers also to their soporific virtue, saying that the plant was called *narcissus* because it was narcotic, and not after the fabled boy: “et a narce narcissum dictum, non a fabuloso puero.” The Arabian writers dwell especially upon its emetic properties, and its stimulant virtues exhibited in curing alopecia, producing abortion, and exciting genital erections by its local irritation. According to Orfila’s experiments upon dogs, the flowers and the bulb are local irritants, internally causing vomiting, purging, and inflammatory gastro-intestinal lesions. Applied to wounds, the extract inflames them and produces all of the above effects, besides affecting the brain and the whole nervous system, causing staggering, anæsthesia, paralysis, and death by paralysis of the lungs and heart. M. Gerrard extracted from the flowering bulbs an alkaloid which in many respects resembles atropine. It dries the mouth; checks the cutaneous circulation; dilates the pupil, especially in topical application to the eye, the dilatation being preceded for a short time by contraction; quickens the pulse; in a great measure antagonizes the effects of muscarine and pilocarpine on the heart of frogs, and, directly applied to the frog’s heart, slows and weakens its contractions. The alkaloid extracted from the bulb after flowering causes copious salivation, and probably increases cutaneous secretion; given internally, contracts the pupils; topically applied, dilates the pupils, but less so than the alkaloid of the flowering plant; slightly relaxes the bowels; and causes some faintness and nausea. An extract of the flowered bulbs exhibits emetic and purgative properties not possessed by the alkaloids. In man the most noticeable effect of *narcissus* is vomiting. From 15 to 30 grains of wild *narcissus*-flowers are said to act as an emetic, especially if given in a decoction prepared from the flowers dried slowly in the sun. In 1876 the infusion was strongly recommended for children when prepared in the following manner: From 30 to 50 grains (Gm. 2–3.30) of *narcissus*-flowers are infused for 15 or 20 minutes in 5 or 6 ounces (Gm. 160–190) of hot water, and strained. When slightly sweetened, children take it without repugnance and vomit within 10 or 12 minutes. The emetic action of *narcissus* has been used to break up *intermittent fever* and relieve *bronchial catarrh* with congestion or obstruction of the air-tubes. Like *ipeca-cuanha*, it has also been prescribed in *dysentery*, especially of the epidemic form. Its influence on the nervous system is attested by the vogue it has enjoyed in *hysteria*, *chorea*, *whooping cough*, and even *epilepsy*. The dose of the powdered flowers is from 15 to 30 grains (Gm. 1–2); of the powdered bulb from 30 grains to 2 drachms (Gm. 2–8) may be given as an emetic.

NASTURTIIUM.—WATER-CRESS.

Cresson de fontaine, Fr.; *Brunnenkresse*, G.

Nasturtium officinale, R. Brown, s. *Sisymbrium Nasturtium*, Linné, s. *Cardamine fontana*, Lamarck.

Nat. Ord.—Cruciferae, Siliquosae.

Description.—The true water-cress is a perennial herb growing in springs, brooks, ponds, and ditches in Europe, Asia, Africa, and North America. The ascending and spreading stem is 1 or 2 feet (30–60 Cm.) long, angular and hollow. The leaves are petiolate, 2 or 3 inches (50–75 Mm.) long, dark-green, pinnate, with from five to fifteen obliquely ovate or roundish oblong leaflets, about $\frac{3}{4}$ inch (18 Mm.) long, or sometimes much smaller, the terminal one being largest, ovate-cordate or oblong, and rather wedge-shaped at the base. The flowers are in loose corymbose racemes, white, and produce linear ascending pods about $\frac{1}{2}$ inch (12 Mm.) long. The fresh plant, bruised, has a pungent odor and a bitterish somewhat biting taste.

Constituents.—On distilling the fresh plant with water a volatile oil is obtained which contains sulphur and is probably identical with oil of mustard.

NASTURTIIUM SYLVESTRE, *R. Brown*, with narrow linear pods, and

NAST. PALUSTRE, *De Candolle*, with oblong or ovoid pods, have similar properties. Both species grow in North America (the former one as an introduced plant), and have pinnatifid toothed leaves and small yellow flowers.

The name *cress* is used for a number of more or less pungent plants, like *garden-cress*, *Lepidium sativum*, *Linne*; *winter-cress*, *Barbarea vulgaris*, *R. Brown*; *bitter-cress*, *Cardamine amara*, *Linne*; *penney-cress*, *Thlaspi arvense*, *Linne*; *wart-cress* or *swine-cress*, *Senecio biera didyma*, *Persoon*; *wall-cress* or *rock-cress*, *Arabis lyrata*, *Linne*. All these plants belong to the natural order Cruciferae. The *Para cress*, *Spilanthes oleracea*, *Jacquin*, is a composite plant. The well-known garden-plants of the order Tropaeolaceae, *Tropaeolum majus*, and *T. minus*, are indigenous to Peru and known as Indian cress or garden nasturtium, *E.*; *Cresson des Indes*, Capucine, *Fr.*; Kapuzinerkresse, *G.*; the buds and unripe fruits are sometimes used like capers.

Medical Action and Uses.—Like several other plants that have a pungent taste, as scurvy-grass (*Cochlearia officinalis*) and horse-radish (*C. armoracia*), water-cress has long been celebrated as a purifier of the blood, and was and is used in the spring to eliminate the crude humors accumulated during the winter. That it increases the appetite, renders the bowels freer, and the urine more abundant is familiarly known. It is a favorite and efficient domestic remedy in many cases of glandular *scrofula* in children, and applied in a poultice to *eczematous* eruptions it sometimes effects a cure. It is also reputed to do good in chronic *bronchitis*. It is best eaten fresh as a salad, but it may be given in decoction or infusion or its expressed juice may be taken in milk.

NECTANDRÆ CORTEX, *Br.*—BEBEERU-BARK.

Nectandra, U. S. 1870; *Cortex beberu*, s. *libiru*.—*Greenheart-bark*, *E.*; *Écorce de bibéru*, *Fr.*; *Bibirurinde*, *G.*

The bark of *Nectandra Rodiei*, *Schomburgk*. Hooker's *Jour. Bot.*, 2d ser.; Bentley and Trimmen, *Med. Plants*, 219.

Nat. Ord.—Lauraceæ.

Origin.—The greenheart is a tree from 60 to 100 feet (18–30 M.) high, growing in British Guiana on hillsides a short distance from the sea, and disappearing farther inland. The small compound racemes of white flowers are situated in the axils of the coriaceous oblong elliptical and acuminate leaves, and produce a subglobular berry about 2 inches (5 Cm.) in diameter, supported by the enlarged cup-shaped tube of the calyx, and containing a single seed nearly the size of the fruit. The wood is very durable and useful in shipbuilding.

Description.—The bark is in flat or somewhat curved pieces, sometimes 1 or 2 feet (30–60 Cm.) long and 4 or 6 inches (10–15 Cm.) wide by $\frac{1}{4}$ inch (6 Mm.) thick, is heavy, hard, and brittle, and consists of liber only. The outer surface is gray-brown, with numerous irregular conchoidal depressions, the ridges between consisting of soft cork, sometimes with light reddish-gray patches containing small suberous warts. The inner surface is cinnamon-brown and rather coarsely striate. The bark breaks with a short and rough granular fracture, which is somewhat fibrous in the inner layer. It has no odor; its taste is astringent and persistently bitter.

Constituents.—Besides tannin, producing green precipitates with iron salts, some starch, and other common constituents, the bark contains an alkaloid, *beberine*, $C_{18}H_{21}NO_5$, discovered by Rodie (1834). In its pure state it is a white bitter fusible powder, soluble in alcohol and ether, according to Walz (1860) identical with *busine*, the alkaloid of *Buxus sempervirens*, *Linne*, and, according to Flückiger (1869), also with *pelosine* and *paricine*. (See PAREIRA BRAVA.) The commercial sulphate of beberine (see page 302) was found by MacLagan (1843) to contain another alkaloid, *sipirine*, which is red-brown, resin-like, and insoluble in ether. MacLagan obtained the alkaloid also from the fruit. It is combined with *beberic acid*, which forms white deliquescent crystals, fuses at $150^{\circ} C.$, and sublimates at $200^{\circ} C.$ Together with Gamgee (1870), he examined the wood and obtained several alkaloids, one of which, *nectandrine*, $C_{20}H_{25}NO_4$, fuses in boiling water, is very soluble in chloroform, little so in ether; sulphuric acid and manganese dioxide produce a green color, changing to violet. The others have not been further examined. It has not been determined whether any one of these alkaloids is identical with *parabarine*, $C_{24}H_{48}N_2O$, which was found by Pavia in box-bark; according to Pavesi and Rotondi

(1874), its sulphate is insoluble in alcohol, its nitrate crystallizes in pearly scales, and its hydrochlorate in minute needles.

Pharmaceutical Uses.—For the preparation of *Beberia sulphas*, *Br.*

Allied Drugs.—COTO-BARK was sent from Bolivia to Europe in 1875. Its origin has not been determined, but it is probably derived from a lauraceous tree. It is met with in flat or curved pieces $\frac{1}{4}$ inch (6 Mm.) or more thick, of a cinnamon-brown color, externally smooth, the inner surface usually darker, and upon the transverse section showing numerous yellow dots of groups of stone-cells and bast-fibres; the bark breaks with a short, granular, and in the inner layer irregular and coarsely splintery, fracture, and has an aromatic odor resembling a mixture of cardamom, cajuput, and camphor, and a bitterish aromatic and pungent taste.

By extracting the bark with ether Jobst and Hesse (1876, 1877) isolated a number of new proximate principles. *Cotoin*, $C_{22}H_{18}O_6$, crystallizes in white fusible prisms, has a biting taste, is readily soluble in alcohol, ether, chloroform, and carbon bisulphide, and with difficulty soluble in benzol, petroleum benzin, and cold water. Nitric acid dissolves it with a blood-red, sulphuric acid with a brown-yellow, and hydrochloric acid with a yellow, color. Ferric salts precipitate its concentrated solutions blackish-brown; subacetate of lead causes a yellow precipitate. Wittstein found in coto-bark also pale-yellow *volatile oil* of a peppery taste, a volatile alkaloid, probably propylamine, resin, starch, etc., and 1.8 per cent. of ash.

PARACOTO-BARK resembles the bark described above in color and appearance, except that the outer layer consists of whitish deeply-fissured cork, and that it is weaker in odor and taste, the odor resembling that of nutmeg.

Paracotoin, $C_{19}H_{12}O_6$, crystallizes in yellowish-white scales, is tasteless, slightly soluble in cold alcohol, is not affected by ferric chloride, and dissolves in sulphuric and nitric acids with a yellow color; solution of potassa converts it into paracotoic acid, paracumarhydrin, and other products.

Leucotin, $C_{21}H_{20}O_6$, and *oxyleucotin*, $C_{21}H_{20}O_7$, are tasteless, and dissolve in sulphuric acid with a dark-yellow, in nitric acid with a blue-green, color; the two compounds are separated by cold alcohol, in which oxyleucotin is sparingly soluble.

Hydrocotoin, $C_{22}H_{20}O_6$, crystallizes in pale-yellow or white prisms or needles, is tasteless, and dissolves in warm nitric acid with a purple-red color.

Cotonetin, $C_{20}H_{16}O_5$, forms delicate white scales which resemble cotoin in behavior.

Both barks contain *piperonylic acid*, $C_8H_6O_4$, which has been obtained by Mielck (1869) among the products of oxidation of piperic acid, and was shown by Fittig and Remsen (1871) to be methylene-protocatechuic acid; it is sublimable, and crystallizes in needles melting at $228^\circ C.$ ($442.4^\circ F.$).

Tincture of coto-bark has been made from 1 part of the bark and 9 parts of alcohol.

Medical Action and Uses.—The bitterness and astringency of nectandra are due in a great measure to its alkaloid, *beberina*. According to its original promoters, *beberina* had all the virtues without the objectionable qualities of quinine, such as the production of tinnitus, headache, etc. In small doses it appeared to be a stomachic tonic. In experiments upon the frog, in which the alkaloid was used hypodermically, it caused tetanic retraction of the limbs in the same manner as quinine, but these effects were not produced by either substance when given by the stomach. Nor did the tetanism resemble that of strychnine, since it was not intensified by external excitation.

In the treatment of *periodical fevers* this substance proves to be very inferior in efficacy to quinine, since it fails in at least one-half of the cases. It has also been vaunted in the treatment of periodical *headaches* and *neuralgias*, as an antiseptic remedy in *consumption*, as a tonic in *atonic dyspepsia*, in *menorrhagia*, *leucorrhœa*, etc. It may, on the whole, be regarded as an imperfect substitute for quinine. The *dose* of *beberine* is from 1 to 3 grains (Gm. 0.06–0.18) as a tonic, and from 5 to 10 grains (Gm. 0.30–0.60) as an anti-periodic medicine. (See *BEBERINÆ SULPHAS*.)

COTO-BARK. Burkart observes that from 8 to 15 grains (Gm. 0.5–1) of coto-bark produces eructations, nausea, a continued feeling of warmth in the stomach, and even vomiting. The tincture, applied to the skin, causes redness and heat. Cotoin and paracotoin are excreted with the urine (*Amer. Jour. Phar.*, Jan. 1880, p. 26).

COTO, although belonging to the same natural family as *Nectandra*, does not in the least resemble it in its properties or medicinal uses. Indeed, there is nothing whatever in its sensible qualities, and especially no astringency, to denote its possession of a power to control sweating and diarrhoea, the affections for which it is chiefly used. Its smell is rather aromatic and its taste acrid and somewhat bitter. In Germany it has been clinically studied by several physicians, whose results substantially agree with one another. The most elaborate report of them has been furnished by Frommüller. Of *diarrhœa*, against which other remedies had for the most part proved useless, colliquative forms following *typhoid fever* or accompanying *phthisis*, it cured the greater number of cases in the former category and palliated all in both diseases. Even when most efficient the medicine could not be abruptly discontinued without risking a return of the symptoms. In the successful cases the quantity of the tincture taken during the day varied from 10

to 500 drops, but the most usual quantity was 50 drops (Gm. 3.30) three times a day. Similar results have been reported by Yeo (*Practitioner*, xxiii. 257), but Dr. Gee gave the "liquid extract of coto-bark for the diarrhoea of phthisis, typhoid fever, and lardaceous disease without the least benefit" (*St. Bart's Rep.*, xv. 232). Large doses are evidently more efficient than small ones. Unless the tincture is well prepared, it occasions an unpleasant burning in the throat; but, properly made, the stomach not only tolerates it, but the appetite improves under its use, which is not apt to be the case when opium, tannic acid, acetate of lead, etc. are used for a similar purpose. Albertoni ascribes the medicinal power of cotoin to a power of dilating the blood-vessels, and thereby increasing absorption. But this rationale would scarcely apply to its utility in sweating. Indeed, its mode of action is unknown.

As regards immoderate sweating, Frommüller observed in the case of a phthisical patient suffering at the same time from colliquative diarrhoea that both symptoms disappeared under full doses of tincture of coto. He prescribed it in ninety-one cases of excessive sweating—in thirty-four with complete, in thirty-six with partial success, and in twenty-one without result. Its beneficial effects generally lasted only one night. It appeared to be more efficient than other medicines commonly used under such circumstances. These results are substantially confirmed by Burkart, Rohne, and Stewart (*Edinb. Med. Jour.*, xxvii. 750), who, as well as Frommüller, found that cotoin and paracotoin produced analogous effects. The latter has been tried subcutaneously in cholera in 3-grain (Gm. 0.20) doses. The urine of patients taking cotoin is said to assume a red color on the addition of concentrated nitric acid, at least during a few hours after the medicine has been used. In the summer complaint of this country, or *cholera infantum*, the medicine is reported to have been efficacious when used in an elixir (Parsons).

Coto-bark is not conveniently given in powder on account of its persistently acrid taste, but the proper dose is stated to be from 5 to 10 grains (Gm. 0.30–0.50), given three or four times a day. Cotoin has been used in doses of $1\frac{1}{2}$ grains (Gm. 0.10), and paracotoin in doses of 4 or 5 grains (Gm. 0.30), three times a day. The tincture appears to have been found the most convenient preparation of coto-bark. It was made with 1 part of the bark to 9 of 85 per cent. alcohol, and given in average doses of about 2 fluidrachms (Gm. 8), sufficiently diluted. Yeo states that as the resin is precipitated from the tincture or fluid extract on the addition of water, either preparation should be given in an emulsion, so that each dose should contain about 5 minims of the active ingredient.

NICCOLI SULPHAS.—SULPHATE OF NICKEL.

Sulfate de nickel, Fr.; *Nickelsulfat*, G.

Formula $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$. Molecular weight 280.

Origin.—The metal nickel was first obtained in 1751 by Cronstedt from *niccolite* or *kupfernickel*, a pale, copper-colored mineral, the composition of which is NiAs . The metal exists in various ores found in Sweden, Germany, and other parts of Europe, and in North America in Pennsylvania and near Lakes Huron and Superior; it is also present in a few mineral waters. It is prepared from the oxide or carbonate by reducing it at a white heat in the presence of charcoal or organic matters.

Preparation.—Sulphate of nickel may be prepared by dissolving pure carbonate of nickel in diluted sulphuric acid, concentrating the solution, and crystallizing at or below 20°C . (68°F .), or precipitating it with alcohol. The salt is extensively manufactured on the large scale from impure carbonate, the process involving the separation of other metals, like arsenic, iron, copper, and cobalt.

Properties.—The salt forms either a green crystalline powder or it is generally seen in emerald-green, transparent, rhombic prisms, which effloresce on exposure, losing $\text{1H}_2\text{O}$, and being at the same time converted into an aggregation of octahedral crystals. A salt containing $6\text{H}_2\text{O}$ is also obtained by crystallization from an acid solution at above 20°C . (68°F .). The salt has a sweetish and styptic taste and a slight acid reaction, is soluble in about 3 parts of water at 15°C . (59°F .), insoluble in alcohol and ether, and loses at 103.3°C . (218°F .) 38.5 per cent. (the salt with $6\text{H}_2\text{O}$, 34.2 per cent.) of water, the remaining molecule of water being expelled above 250°C . (482°F .). The solution of nickel sulphate, on being mixed with a saturated solution of ammonium sulphate in excess, gives a precipitate of *nickel-ammonium sulphate*, $(\text{NH}_4)_2\text{Ni}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$. This salt is blue-green, almost insoluble in solutions of alkali sulphates, but soluble in about 8 parts of water; it, like the sulphate, is largely used for the electro-plating of iron, copper, and other metals with nickel.

Allied Salts and Metallic Nickel.—**NICCOLI CARBONAS.**—Carbonate of nickel, *E.*: Carbonate niccolique, *Fr.*: Nickelkarbonat, *G.*—It is pale-green or blackish-green, of variable composition, and is prepared by precipitating the solution of a nickel salt with sodium or potassium carbonate.

NICCOLI BROMIDUM.—Bromide of nickel, *E.*: Bromure de nickel, *Fr.*: Nickelbromür, *G.* $\text{NiBr}_2 \cdot 3\text{H}_2\text{O}$; mol. weight 271.6.—It is prepared by digesting nickel with bromine and water, or by dissolving nickel carbonate in hydrobromic acid and crystallizing. It crystallizes in green deliquescent needles or prisms, which are soluble in alcohol, ether, and water; the latter solution on exposure is decomposed, depositing nickel hydrate.

NICCOLI CHLORIDUM.—Chloride of nickel, *E.*: Chlorure de nickel, *Fr.*: Nickelchlorür, *G.*—The hydrated salt is green, very deliquescent, and contains $6\text{H}_2\text{O} = 45.4$ per cent. The anhydrous chloride is yellow, or, in the presence of cobalt, has a green tint; it sublimes in yellow lustrous scales.

NICKEL is a malleable metal, resembling silver in color and lustre. It is attracted by the magnet, has the density 8.8, melts at a somewhat lower temperature than iron or cobalt, does not readily tarnish on exposure, and is but little attacked by dilute acids. The *sesquioxide*, Ni_2O_3 , and its hydrates are black or black-brown, and dissolves in acids with the evolution of oxygen. The *monoxide*, NiO , is greenish-gray or yellowish-gray: its hydrate is a green crystalline powder, and its salts are likewise green, or in the anhydrous state yellow, and have a slight acid reaction. The solution of the acetate gives a black precipitate with sulphuretted hydrogen; other nickel salts with ammonium sulphide. Alkalies and alkali carbonates produce green or pale-green precipitates, which dissolve in ammonia with a blue, and in ammonium carbonate with a greenish-blue, color. Potassium ferrocyanide produces greenish-white precipitates; potassium cyanide, a similar precipitate soluble in excess of the cyanide: and if to this solution caustic soda and chloride be added and heat applied, a precipitate of black nickel hydrate is produced (difference from cobalt). A concentrated solution of oxalic acid precipitates nearly all the metal as *nickel oxalate* from simple salts, but not from solutions of the double salts.

Action and Uses.—In 1824, Gmelin inferred that *sulphate* of nickel is not active, since 20 grains of it produced no effect upon a dog except depression and vomiting, and only after 2 hours. 10 grains injected into the jugular vein of a dog caused its death by arresting the heart, and 5 grains occasioned vomiting, diarrhoea, prostration, partial paralysis, and feeble action of the heart, from which, however, the animal recovered. Injected into the connective tissue, a solution of the salt was absorbed, but induced no symptoms (*Edinb. Med. and Surg. Jour.*, xxvi. 136). In 1852, Simpson stated that this preparation appeared to act as a gentle tonic, that it does not occasion nausea and vomiting like the sulphates of zinc and copper, and that its action and that of manganese were comparable to the action of iron. He reported the cure by it of inveterate periodical *neuralgia* of the face after it had resisted iron, quinine, and many other medicines. He prescribed it in doses of from $\frac{1}{2}$ to 1 grain three times a day (*Month. Jour. of Med. Sci.*, 3d Ser., vi. 136). In 1869, Broadbent attributed the cure of *anæmia* and *amenorrhœa* to the *chloride* of nickel in 2-grain doses (*Trans. Clin. Soc. Lond.*, ii. 125). By Bernatzik it was compared to cerium, and by Schuhhardt to iron and manganese (*Arzneimittel-lehre*, ii. 106, 283). Dr. J. M. Da Costa (pamphlet, 1883) found that in doses of 5 grains the *sulphate* caused giddiness as well as nausea, but no such soporific effect as had been attributed to it. The doses employed by him varied from 1 to 3 grains. He thought that it relieved the pains of rheumatism, checked diarrhoea, and allayed irregularity due to valvular disease of the heart. In some instances it appeared to him beneficial in chronic gastric catarrh. It was of no use in night-sweats nor in typhoid fever. *Bromide* of nickel, used by Dr. Da Costa in doses of from 5 to 10 grains, seemed to him to exert the peculiar power of other bromides, but in smaller doses than they. In several cases it suspended *epileptic* seizures after the failure to do so of the alkaline bromides. He found that it slightly lowered the temperature, affected the pulse but little if at all, did not act on the bowels or the skin, and perhaps increased the urine a little. He concluded that "its effect on the nervous system is that of a sedative, without, however, producing a weakening or depressing influence."

NIGELLA.—FENNEL-FLOWER.

Faux cumin, *Fr.*; *Schwarzkümmel*, *G.*

The seeds of *Nigella sativa*, *Linné*, and of *Nig. damascena*, *Linné*.

Nat. Ord.—Ranunculaceæ, Helleboreæ.

Origin.—Both plants are annuals, indigenous to Southern Europe and the Levant. They have finely-divided leaves like fennel: the second species has also a similar involucre. The fruit consists of five united follicles, which contain numerous seeds. Both

plants are cultivated in gardens, and are known respectively as *nutmeg-flower* and *ragged lady*.

Description.—The seeds are about $\frac{1}{10}$ inch (2.5 Mm.) long, triangular-ovate, rough, of a dull-black color, internally white, contain a fleshy albumen enclosing a small straight embryo, and have a somewhat acrid taste. When rubbed the seeds exhale a peculiar odor, that of the first species being camphoraceous and resembling cajuput, while that of the second species resembles the odor of strawberries. The latter are sometimes sold as *magnolia-seeds*; they differ from the former also in being rounded at the angles and having the testa deeply netted-wrinkled.

Constituents.—Reinsch (1841) obtained 35 per cent. of fixed oil, which, according to Lepine, is orange-yellow and solidifies at 2° C. (35.6° F.). Flückiger (1871) found in it myristin, palmitin, and stearin. The volatile oil is lighter than water, colorless, shows a blue fluorescence, has an odor different from that of the seed, and, according to Flückiger, consists of a terpene and of the compound $C_{20}H_{24}O$. Reinsch's *nigellin* is an extract-like yellow mass having the consistence of turpentine and a bitter taste. H. G. Greenish ascertained (1880-82) that petroleum benzin becomes fluorescent with the seeds of *N. damascena*, but not with those of *N. sativa*, which contain *melanthin*, not found in the former seeds. This principle is nearly insoluble in water, ether, benzol, benzin, and carbon bisulphide, very soluble in alcohol, is acrid, foams similar to parillin, consists of $C_{20}H_{30}O_7$, and by acids is split into sugar and *melanthigenin*, $C_{15}H_{20}O_2$; both principles are colored dark-violet by warm sulphuric acid and rose-red by cold pure sulphuric acid.

Medical Action and Uses.—*Nigella* is closely analogous in its properties to coriander, anise, and cumin, and like them is used in the East as a condiment for food, and medicinally as a carminative, aphrodisiac, emmenagogue, galactagogue, diuretic, and expectorant.

NITROBENZOLUM.—NITROBENZOL.

Oil of mirbane, E.; *Nitrobenzène*, *Essence de mirbane*, Fr.; *Mirbanöl*, G.

Formula $C_6H_5NO_2$. Molecular weight 123.

Preparation.—Benzol is added in small portions to warm fuming nitric acid, when a violent action takes place and a dark-red liquid is formed, which is mixed with water and the oily precipitate washed with the same liquid. 100 parts of benzol yield between 135 and 140 parts of nitrobenzol.

Properties.—Nitrobenzol is a yellowish oily liquid having the spec. grav. 1.209, crystallizing in needles at 3° C. (37.4° F.), and boiling at 205° C. (401° F.). It has a strong odor resembling that of oil of bitter almond—hence the incorrect name *artificial oil of bitter almonds*—a sweet taste, and dissolves in concentrated sulphuric and nitric acid, and in all proportions in alcohol and ether. In its alcoholic solution it is readily converted into aniline through the influence of nascent hydrogen.

The different benzols yield also different nitro-products. One has the specific gravity 1.19, boils between 210° and 220° C. (410° and 428° F.), and has a cinnamon-like or unpleasant fatty odor, which is still more unpleasant in nitrobenzol boiling between 225° and 235° C. (437° and 455° F.).

Pharmaceutical Uses.—The low-boiling nitrobenzol is often used for scenting soaps and in various perfumes as a tolerably good substitute for the more costly oil of bitter almond, which is sometimes adulterated with it (see OL. AMYGD. AMARÆ), but its most important use is in the manufacture of aniline (see page 205).

Physiological Action.—*On Animals*: The experiments of Dr. Letheby and others show that the toxical phenomena vary not only with the dose of this poison, but very singularly in the time of their coming on, so that several or even many hours may elapse before they appear. Filehne's experiments have shown very clearly that under favorable circumstances nitrobenzol is rapidly absorbed and produces its effects rapidly. The cases in which they were notably delayed he explains by saying that the liquid does not readily mix with the contents of the stomach, and hence if this organ contains much food, its surface may not be reached by the poison until a considerable interval has elapsed. This explanation may apply to many cases, but it does not to those in which, as stated below, the action of the poison was retarded even for days. When the poison is speedily fatal the animal is affected with giddiness, inability to walk, complete loss of voluntary power, occasional spasms of the dorsal muscles, or general epileptiform convulsions; the pupils are widely dilated, the heart's action is tumultuous or irregular, and the breathing difficult. Consciousness is retained until life is extinct. When the action of the poison is slower

and its visible effects are delayed for several days, there is suddenly observed a look of distress, perhaps vomiting, an epileptiform fit, followed by exhaustion and then by renewed fits, which occur at irregular intervals; between them the limbs are in constant motion. Death takes place through exhaustion, or else voluntary power is gradually restored, and the animal recovers. The post-mortem appearances consist of extreme congestion of the blood-vessels of the brain and its membranes; the cavities of the heart and the veins are full of black, coagulated blood; the lungs are congested to a less degree, but there is no trace of gastric lesions. All of the above phenomena relate to the action of nitrobenzol when introduced into the stomach. When it is injected into a blood-vessel it is mortal almost as rapidly as prussic acid. Within a minute it destroys a rabbit, with convulsions and dilated pupils. If, however, it is very gradually introduced, there may be paralysis without spasm (Filehne).

On Man: Numerous cases have been published of poisoning by nitrobenzol—sometimes by its being swallowed, sometimes by the inhalation of its fumes, and sometimes by its application to the skin. A remarkable illustration of the potency of this poison is furnished by several cases of females affected by the odor of the so-called "almond glycerin soap," and by that of a person who, while using such a soap in a warm bath, fainted from the effects of nitrobenzol set free by the heat, and was ill for some time afterward. A case is also recorded of a man who, having used a liniment containing this product in the treatment of scabies, became partially paralyzed, while his head was drawn back, and his face, hands, mouth, and pharynx were all cyanosed, and the breath and matters vomited smelled of bitter almonds. In this case, as in some others, the blue tint remained for at least a week. The symptoms produced in man are identical with those observed in animals, except the purple color of the skin, which appears to be due in part to venous congestion, but in part also to the inability of the blood to absorb oxygen. This condition of the blood helps to explain the dyspnoea which attends some cases of poisoning by this substance, and also the extreme cyanosis, which so far surpasses both in degree and duration that which is due to merely asphyxiating causes. The opinion that this blue color of the skin is in part due to the presence of anilin derived from the decomposition of nitrobenzol in the body is ascribed by Filehne to an error of manipulation by which anilin was developed. The mode of death and the lesions found post-mortem are also essentially the same as in animals—the tarry dark blood, congested lungs, heart and brain, etc. In one case the liver is described as being of a deep-purple color. All these phenomena and lesions support the conclusion of Lewin (*Virchow's Archiv*, lxxvi. 443), that the poisonous action of nitrobenzol depends upon its destructive effect upon the red blood-corpuscles, which prevents the supply of oxygen essential to life. Whether recovery or death occur, the peculiar odor of nitrobenzol persists for many days. The probable fatal dose of nitrobenzol may be stated to be between a few drops and 2 drachms.

Medical Uses.—The only disease, so far as we are informed, in which the preparation has been used is *scabies*, but its dangerous effects from accidental conditions, and the case of poisoning by it in this very disease to which reference has been made, ought to exclude it altogether from medical practice.

In *poisoning* by nitrobenzol the proper remedies consist of emetics to remove the poison in the stomach, and of stimulants, internally and externally, carbonate of ammonia, electricity, artificial respiration, the hot bath, and a simultaneous cold douche upon the head and spine, frictions of the skin, etc. Oil and alcohol, which dissolve the poison, are contraindicated.

Nitropentan has been the subject of some physiological experiments. In dogs and cats, when the inhalations were continued from 8 minutes to 1 hour, convulsions began to occur which gradually increased in intensity until they passed into true epilepsy. The peristaltic movements of the intestines were quickened and the feces were evacuated. The urine was also discharged; sometimes the saliva flowed profusely, and the pupils were dilated. The pulse was not materially affected, and the vessels of the pia mater underwent no change during the inhalation (Schadow).

NITROGENII MONOXIDUM.—NITROUS OXIDE.

Laughing gas, E.; *Oxyde nitreux*, *Protoxyde d'azote*, Fr.; *Stickstoffoxydul*, *Lachgas*, G. Formula N_2O . Molecular weight 44.

Origin.—Nitrous oxide was first obtained by Priestley (1772) by acting upon nitric oxide with moist iron filings; he also noticed that ignited bodies burn in this gas with a brighter flame than in atmospheric air. The composition of the gas was determined by

Deimann and Troostwijk (1793), who prepared it from ammonium nitrate. H. Davy (1800) observed its exhilarating effects.

Preparation.—Nitrate of ammonium which is absolutely free from chloride is gradually heated to about 200° C. (392° F.), when the decomposition commences, and the heat may be slowly increased. The salt yields then water and nitrous oxide, without other products of decomposition; NH_4NO_3 yields $2\text{H}_2\text{O} + \text{N}_2\text{O}$. The gas is passed through a little warm water, which will retain any undecomposed salt or other product without retaining much of the gas. (For other precautions in the preparation of this gas refer to the decomposition of AMMONII NITRAS, on page 185.)

Properties.—Nitrous oxide is a colorless gas of a very slight agreeable odor and a sweetish taste. It has the specific gravity 1.6 (Dalton), and a liter of it at 0° C. (32° F.) weighs 1.97 Gm. It is not inflammable, but supports the combustion of ignited bodies, which burn more vigorously than in the open air. By the aid of pressure and cold it may be condensed into a thin, very mobile, colorless liquid, which at a temperature of about -100° C. (-148° F.) congeals to colorless crystals. The gas is soluble in water, alcohol, ether, volatile and fixed oils.

Nitrous Oxide Water.—The solubility of nitrous oxide in water has been determined by Carius (1855) as follows: Water absorbs at a barometric pressure of .76 meter and a temperature of

0°	5°	10°	15°	20°	25° C.,
1.3052	1.0954	.9196	.7778	.6700	.5963 measures of the gas.

Such an aqueous solution, prepared under a pressure of about five atmospheres, has been employed under the name of *oxygenous aerated water*.

Physiological Action.—The primary effect of inhaling nitrous oxide gas is stimulation of the whole system; a tingling sensation is felt all over the body, the senses seem unnaturally acute, the pulse become stronger and more frequent, the breathing is more rapid and shallow, and the face grows pale. If the inhalation is interrupted at this period a lively intoxication is developed. It was formerly the custom to have semi-public exhibitions of this appropriately called "laughing gas," in which one of the most familiar phenomena was a high degree of mental excitement, generally exhibited in rhapsodical declamation or singing, but sometimes also in a sudden fit of violent pugnacity, which subsided abruptly when the vapor was exhaled. But if the inspiration is not interrupted the breathing in about $1\frac{1}{2}$ minutes begins to be stertorous; at the same time the pallor of the face is replaced by a cyanotic hue, and complete unconsciousness and anaesthesia ensue. Without a renewal of the inhalation it does not last more than a minute or two. Unlike ether or chloroform, it is apt to occasion muscular twitching, or even rigidity. In general, feeble persons are more quickly affected than the strong—children, females, and the aged more speedily than adult males.

The number of deaths due to the administration of this gas is surprisingly small when compared with those following chloroform, and even ether, and, as in the case of the latter agent, they may always, or nearly so, be fairly ascribed to the special condition of the patient or to the mode of administration of the anaesthetic. According to the statistics of Darin, 53 deaths occurred in 152,260 administrations of chloroform, or 1 : 2872; 4 in 92,815 of ether, or 1 : 23,203; and 3 in 300,000 of gas, or 1 : 100,000, one of which was due to an accident—namely, the falling of a cork into the air-passages. Other ill effects have occasionally been noticed; *e. g.* coma of several days' duration, hemiplegia, temporary catalepsy or hysteria, clonic convulsions, etc.

The mode in which nitrous oxide gas acts has been variously explained, and while it remains as difficult as ever to understand its soporific and anaesthetic power, it is very easy to refute the principal error in regard to it; which is, that it is merely an asphyxiating agent whose action consists in excluding the atmosphere from the lungs. This simple but very absurd hypothesis would liken the presence of the gas in the air-passages to that of a foreign body, or, more precisely, to that of an unirritating but irrespirable gas. But carbonic acid is such a gas, and, although it may prove fatal, it does not produce the discoloration of the skin which is characteristic of nitrous oxide. Besides, nitrous oxide is not irrespirable. The experiments of Zimmermann show that rabbits and pigeons may be confined in it not only for minutes, but for hours, and yet return to active life. It must not be forgotten that it not only contains oxygen, but a far larger proportion of it than exists in atmospheric air, and that very possibly a portion of the gas is decomposed, furnishing an amount of oxygen sufficient to maintain life, while the bulk of it remains unchanged and induces cyanosis, unconsciousness, and anaesthesia. This conjecture is not

a mere hypothesis, for it is established by experiment that venous blood introduced into an atmosphere of nitrous oxide assumes the arterial color; that phosphorus undergoes oxidation in it; that seeds germinate and grow in it; and, above all, that it does not put out the light of a burning taper. Finally, a most important and, indeed, capital, fact is, that in the series of phenomena which it produces in animals immersed in it the organ which remains longest in action is the heart; and as the gas is very rapidly eliminated from the system, the brain and the lungs are soon relieved from its influence, while the heart continues to pulsate and repair whatever temporary damage may have been produced. To these conclusive scientific reasons must be added the equally conclusive practical observation made by every one who has witnessed the exhibition of nitrous oxide as "exhilarating gas." It was of common occurrence during such experiments that the subjects of them, while in a state of high mental exhilaration with combative propensities, inflicted severe injuries upon themselves, even to the breaking of the bones of the hand by striking solid objects, and yet they neither manifested any sense of pain at the time nor had any recollection of the cause of the injury on their return to consciousness.

Surgical Uses.—Nitrous oxide has been used in surgical operations, but chiefly in those requiring a comparatively short time for their performance. *Teeth* have been extracted with its aid in cases innumerable in this country and in Europe, and whoever has experienced its effects must be satisfied with the efficiency and convenience of its use. All surgical operations which can be quickly completed, from the opening of *abscesses* to the operation for *cataract*, have been successfully performed with its aid; and in numerous instances it has sufficed for operations lasting from 15 to 20 minutes. In 1865, Dr. Ziegler of Philadelphia proposed the inhalation of this gas for a variety of disorders, the chief of which were nervous and asthenic, and included *neuralgia*, *anæsthesia*, *hypochondria*, *insomnia*, etc., and it was employed soon afterward by Dr. Benjamin Lee (*Med. Record*, xvii. 494). It did not, however, seem to find many advocates. In 1880 attention was directed to it anew by Drs. Blake and Hamilton (*Med. Record*, xvii. 118; *Boston Med. and Surg. Jour.*, May, 1880, p. 469). In all of these instances the exhilarating, and not the anæsthetic, action of the gas was sought, and it was believed to act as a stimulant of the nervous system and the heart, very much as a moderate dose of alcohol does. It, however, did not retain its vogue. Nitrous oxide has also been employed as an anæsthetic in labor. According to Klikewitsch, four or five inhalations abolish sensation, but not consciousness; it involves neither danger nor inconvenience, and may be administered by an intelligent nurse (*Med. Record*, xxi. 514).

Administration.—The nostrils being closed, the gas may be inspired from the reservoir in which it is collected or from caoutchouc bags through a tube and mouth-piece furnished with valves opening outward to permit the breathed air to escape during expiration. It is also kept in wrought-iron vessels in a highly condensed or even a liquid state, and may thus be conveniently transported from place to place.

Bert proposed to prevent the "asphyxia" produced by nitrous oxide by mixing 85 parts of this gas with 15 of oxygen in a chamber filled with compressed air. Several surgical operations of considerable duration were successfully performed under these circumstances (*Bull. et Mém. de la Soc. de thérap.*, 1879, p. 71). But the method does not appear to have been accepted.

NITROGLYCERINUM.—NITROGLYCERIN.

Trinitoglycerin, Glonoin.

Formula $C_3H_5(NO_2)_3O_3$. Molecular weight 227.

Preparation.—Nitroglycerin was discovered by Sobrero (1847), and is at the present time prepared on a large scale by slight modifications of the process proposed by the discoverer and by E. Kopp. To about 7 pounds of a mixture composed of 1 part of nitric acid sp. gr. 1.47 and 2 parts of strong sulphuric acid, 1 pound of glycerin is slowly added, with frequent stirring and with the precaution of preventing the temperature from rising above 26.6° C. (80° F.). The mixture is then poured into a large quantity of water, and the oily sediment well washed with a diluted solution of alkali and of water. 10 parts of pure glycerin yield 19 parts of nitroglycerin.

Properties.—Nitroglycerin is a colorless or pale-yellowish oily liquid having the density 1.60 at 15° C. (59° F.), and when exposed to a low temperature crystallizes in long needles. It is without odor, but its vapors produce intense headache; its taste is sweet and pungently aromatic. When ignited in the open air it burns quietly and incom-

pletely, but when heated in closed vessels or by percussion it explodes with great violence. On keeping it is gradually decomposed, oxalic acid being formed, besides nitrous acid and other gases, from the pressure of which explosions are apt to occur. Nitroglycerin forms the basis of various blasting-compounds known as *dynamite*, *giant powder*, *glyoglin*, *duadin*, etc. It is nearly insoluble in water, but dissolves freely in ether, alcohol, and methylic alcohol; these solutions will likewise explode by percussion with a wet hammer. According to Alfred Nobel, who first prepared (1862) nitroglycerin for blasting purposes in Sweden, 1 volume of this compound yields about 10,400 volumes of gases and vapors. The products of this decomposition are water, carbon dioxide, nitrous oxide, and nitrogen.

Physiological Action.—Nitroglycerin is a powerful poison, and exerts a marked effect upon the nervous system even when given in minute doses. Its general effects may be summarily described as "accelerated respiration, paralysis, loss of reflex action, and apparently, to a great degree, of sensation, and death from stoppage of the respiration" (Brunton and Tait). In frogs it induces lethargy and paralysis, alternating with clonic and tonic convulsions; in cats and rabbits, convulsions, tetanus, paralysis, spasmodic breathing, frequent and feeble pulse, general anesthesia, and death; and in dogs, the same effects, besides salivation and vomiting. On dissection the brain may be either pale or congested, and the lungs are engorged with blood, but the heart is empty. In man the symptoms following a dose of 2 drops of a 1 per cent. solution are said to be slight flushing of the face, a decrease in the fulness of the arteries, a rise in the pulse-rate, subsequent intense pallor, and a feeling of faintness lasting for a quarter of an hour. These effects appear, however, to grow milder if the medicine is repeated, and it is said that in one case the dose was ultimately increased to 20 minims of the solution described below every four hours (Murrell). It seems that its effects and those of nitrite of amyl are very similar. Both accelerate the action of the heart, but the influence of nitroglycerin is developed more slowly and lasts longer than that of nitrite of amyl. Several cases of death from poisoning with nitroglycerin have been reported (*Practitioner*, xxiv. 38)—in one case from rubbing a single drop upon the forehead for headache (Werber). A man and a woman partook of soup and coffee in which were 30 grains of dynamite. The symptoms were violent vomiting, burning pain in the head and stomach, and bloody evacuations. The woman died in 2½ and the man in 3 days (*Amer. Jour. Phar.*, li. 304).

Medical Uses.—When this preparation was first known it was for a short time employed in the treatment of certain functional nervous disorders, such as *asthma*, *epilepsy*, *headache*, etc., but it had quite fallen into disuse when Mr. Murrell (1879) claimed for it remarkable virtues in *angina pectoris*. The patients were at first placed upon a short course of camphor-water, after which a drop of the 1 per cent. solution of nitroglycerin in ½ ounce of water was ordered to be taken every four hours. His results have been confirmed by many physicians. Mr. Robson states that if the medicine be continued in gradually-increasing doses the attacks become less frequent as well as less intense (*Practitioner*, xxiv. 445). Dr. McCall Anderson (*Glasgow Med. Jour.*, July, 1881, p. 33) and Dr. Hammond (*New York Jour. of Med.*, Dec. 1882, p. 662) give similar testimony. As was to have been expected, not all cases of *angina pectoris* are benefited by this or by any other medicine. Those in which it acts most favorably are freest from organic lesions. Mr. Robson claims that it gives prompt relief in *asthma*, and others that it is of great use in *migraine* with pallor of the skin, in *puerperal convulsions*, and even in *epilepsy* (Hammond, *Med. Record*, xx. 471); that is to say, in the diseases for which it was originally used. As Huchard expresses it (*Bull. de théér.*, civ. 345), this agent, by congesting the nervous centres and paralyzing the capillaries, is serviceable in all conditions involving cerebral anæmia (nervous headache, vertigo, impoverishment of the blood) or cardiac debility (fatty degeneration, *angina pectoris*, Corrigan's disease, etc.). In *uræmic asthma* it acts like nitrite of amyl to relieve the distress and terminate the paroxysm. In *toothache* the 1 per cent. solution, applied on cotton wool, is stated to relieve the pain. It is also claimed that it increases the quantity of the urine and of its solid contents in chronic *Bright's disease* by "relieving the vascular tension" (*Braithwaite's Retros.*, Amer. ed., 1883, p. 212). If diminished secretion of the urinary solids be due to fibrosis of the renal capillaries, this explanation is inadequate, although the clinical statement may be correct.

The proper antidotes for poisoning by nitroglycerin are stimulants—*e. g.*, alcohol, ammonia, coffee. If the patient is seen early, a mustard emetic should be administered.

TABELLE NITROGLYCERINI, Br. These tablets of nitroglycerin are to be made of chocolate, each weighing 2½ grains and containing $\frac{1}{100}$ grain pure nitroglycerin.

NUX VOMICA, U. S., Br.—NUX VOMICA.

Semen strychni, P. G.; *Semen nucis vomicæ*.—Poison-nut, Quaker buttons, E.; *Noix vomiques*, Fr.; *Krühenaugen*, *Brechnuss*, G.

The seeds of *Strychnos Nux vomica*, *Linneé*. Steph. and Church, *Med. Bot.*, plate 52; Bentley and Trimen, *Med. Plants*, 178.

Nat. Ord.—Loganiaceæ.

Origin.—The tree has a short, thick, often crooked trunk, opposite, oval, glossy, three- to five-nerved leaves, and small, funnel-shaped whitish flowers in small, terminal, paniculate cymes: the smooth, orange-colored berry is globular, about 2 inches (5 Cm.) in diameter, and contains about five seeds. The tree is common in many parts of Hindostan, Farther India, some of the East India Islands, and as *St. lucida*, *R. Brown*, is also found in Northern Australia. All parts of the plant possess a bitter taste, and are probably poisonous; the bark has at one time been sold in place of angustura-bark (see page 204). The white, gelatinous pulp of the fruit, it has been stated, is eaten in India by birds; it, however, contains strychnine (*Pharmacographia*). The seed is the only official portion. The quantity imported into the United States was 460,000 pounds in 1877 and 172,900 pounds in 1881.

Description.—*Nux vomica* is in the form of an orbicular disk an inch (25 Mm.) or less in diameter, and $\frac{1}{8}$ to $\frac{1}{4}$ inch (4 to 6 Mm.) thick, nearly flat, or convex on one side and concave on the other, with the margin frequently thickened. The surface is of a grayish or greenish-gray color, and has a slight silky lustre from the closely-appressed soft hairs, directed toward the circumference and forming a soft ridge on the edge. Where the hairs have been rubbed off the dull-brownish testa becomes visible. In the centre of the concave side is the hilum, connected by a slightly elevated raphe with the chalaza, which forms a small protuberance on the edge in the immediate vicinity of the radicle. Schleiden, Berg, and others regard the latter as the hilum and the central scar as the chalaza. The thin testa encloses a yellowish-gray, somewhat translucent, horny, and very hard albumen (endosperm), which is of the same form as the seed, but has within it a large, flat, circular cavity. After softening the seed in hot water the edge may be readily trimmed down with a knife and the albumen split into two disks, which were united with each other merely on the margin to the width of about $\frac{1}{12}$ inch (2 Mm.). The embryo is about $\frac{3}{8}$ inch (9 Mm.) long, and has a thick, club-shaped radicle and a pair of pale-greenish delicately seven-nerved, heart-shaped cotyledons $\frac{1}{3}$ inch (5 Mm.) in length, and projecting into the circular cavity. The seed is inodorous, but possesses a persistently bitter taste.

Nux vomica is very difficult to powder, owing to the horny condition of the albumen. The powdering is considerably facilitated by drying the entire seeds for two or three days and breaking them up into several pieces, which are again dried for several days by means of warm air, and then reduced to powder of the desired fineness. If a drug-mill with chilled iron grinding-plates, admitting of regulation as to different degrees of fineness, be used, much labor may be saved in the final powdering in an iron mortar provided with a heavy pestle. Powdered *nux vomica* is of a light gray-greenish color.

Constituents.—The horny nature of *nux vomica* is probably due to protein compounds, of which it contains about 11.3 per cent. (*Pharmacographia*). Gummy matter,

fat, sugar, and *igasuric* acid, besides the alkaloids, are also contained in it. The acid was discovered by Pelletier and Caventou (1819), and by Höhn (1873) was regarded as a kind of tannin; the latter obtained it as an amorphous, yellowish-white mass of a strongly acid and somewhat astringent taste; its solution is colored dark-green by ferric salts, precipitated yellow by acetate of lead, and rapidly reduces an ammoniacal solution of silver.

The bitter and poisonous alkaloids *strychnine* and *brucine* are the medically important constituents of *nux vomica*, and are present in variable quantity: Dunstan and Short (1883) analyzed seven different commercial samples, in which the total amount of alkaloids varied between 2.74 per cent. in small Madras *nux vomica* and 3.90 per cent. in large silky Bombay *nux vomica*. (For an account of the first alkaloid, which is present to the amount of $\frac{1}{4}$ to $\frac{1}{2}$ per cent., see the article STRYCHNINA in this work.)

Brucine, $C_{23}H_{26}N_2O_4$, likewise varies in quantity; Merck obtained only 0.12, Wittstein 0.5, Mayer 1.10 per cent.; by the latter it was estimated by means of potassio-mercuric iodide, and the presence of *igasurine* (see below) was not taken into account. The alkaloid was discovered by Pelletier and Caventou (1819) in the false *angustura-bark*, which was then supposed to be derived from *Brucea antidysenterica*, Miller, an Abyssinian shrub. It is one of the by-products of the manufacture of *strychnine*, and is obtained from the mother-liquor and alcoholic washings by neutralizing them with sulphuric acid, evaporating to crystallization, removing the mother-liquor, purifying the crystals by treatment with animal charcoal, precipitating with ammonia, and recrystallizing from boiling 80 per cent. alcohol; it contains then $4H_2O$. The anhydrous alkaloid dissolves in 850 parts of cold and 500 parts of boiling water (Pelletier and Caventou), while, according to Duflos, the crystallized alkaloid requires only 320 and 150 parts of water respectively. It is soluble in 7 parts of chloroform (Schlimpert), in 1.5 parts of alcohol, and in 70 parts of glycerin (Cap and Garot). It is soluble also in ammonia, creasote, amyl alcohol, and very slightly so in benzin, volatile and fixed oils, and is insoluble in ether. It fuses in its water of crystallization at a little over $100^\circ C.$ ($212^\circ F.$), and the anhydrous alkaloid, according to Claus and Roehre (1881), at $178^\circ C.$ ($352.4^\circ F.$), yielding a colorless liquid; at a higher heat it burns, leaving voluminous charcoal. In contact with strong nitric acid *brucine* acquires a blood-red color, which changes to orange, and finally yellow; if now stannous chloride be added, a beautiful violet-red is produced. A similar color is obtained by using sulphurous acid, and lustrous brick-red needles are formed by using ammonium sulphide in place of stannous chloride. These reactions are not interfered with by the presence of a little *strychnine*. A number of the colored compounds thus produced appear to possess little stability; but Roehre (1878, 1881) isolated the red compound, which is *dinitrobrucine*, forms a bright vermilion-red amorphous powder, and is insoluble in ether, very sparingly soluble in alcohol, but freely soluble in water. The end-product of the reaction of nitric acid upon *brucine* was ascertained by Strecker (1854) to be a weak base, *kakoteline*, $C_{20}H_{22}N_2O_5$, which forms orange-colored scales insoluble in water, but dissolving with a yellow color in ammonia, becoming green and brown on heating. Commercial *brucine* generally contains traces of *strychnine*, as proven by Cowley (1876) and Shenstone (1877), and, according to the latter, may be completely freed from it by partial precipitation, *brucine* being precipitated from its solutions by *strychnine*.

Igasurine was discovered by Desnoix (1854) by concentrating the filtrate and washings of the lime precipitate in the decoction of *nux vomica*. The crystals thus obtained are stated by Schützenberger (1858) to be a mixture of not less than nine different alkaloids, which he distinguished by prefixing to *igasurine* the letters *a*, *b*, *c*, etc. However, Jørgensen (1871) and Shenstone (1877, 1881) found the supposed *igasurine* to be impure *brucine*, though it is not unlikely that one or more other alkaloids may be present. (See STRYCHNINA.)

Other Species of Strychnos.—STRYCHNOS TIEUTE, *Leschenault*, is indigenous in Java; the seeds closely resemble *nux vomica*, but are smaller and whiter in color. The decoction of the root-bark, evaporated to an extract, is the principal ingredient of the arrow-poison, *upas-tieute*; it contains *strychnine* and *brucine*.

STR. POTATORUM, *Linné*, is indigenous to India. The seeds are subglobose, $\frac{1}{2}$ inch (12 Mm.) or less in diameter, brownish-gray in color, and of an insipid not bitter taste. They do not contain *strychnine*, and are used in India as *clearing nuts* for cleansing muddy water, also in diabetes and as an emetic. In 1871 they were sent to the United States as *Indian-gum nuts*.

STR. COLEBRINA, *Linné*. This yields the true *liquum colubrinum*, in place of which the branches of the *nux vomica* tree are often sold in India. It differs from the latter in being more crooked and knotty; the wood is harder and darker colored; the bark has bright rust-colored

warts, is thicker, and has more scattered stone-cells of a bright-yellow color. All parts of the plant are bitter and poisonous; the wood was found by Pelletier and Caventou to contain strychnine and brucine.

STR. GAUTHIERIANA, *Pierre*. The bark is used in China as *hoàng-nân*; it resembles nux-vomica bark, but is thinner, blackish-gray, more verrucose, and upon transverse section shows more irregular striæ and fewer stone-cells; it contains strychnine and brucine.

AKAZGA—*M'boundou, Boundou, Ikaja, or Quai*—is a shrubby plant indigenous to the equatorial region of Western Africa, and appears to be a hitherto unknown species of *Strychnos*. It is about 6 feet (1.8 M.) high, with a stem nearly an inch (25 Mm.) in diameter. The dense hard wood is covered with a firmly-adhering bark having sometimes numerous yellow tubercles, of a yellowish-orange, or in some parts light-red, color, with a light-brown inner surface, and characterized by a continuous layer, three or four cells deep, of indurated parenchyma. The leaves are opposite, oval-acuminate in shape, and attain a length of 3 to 6 and even 12 inches (8 to 30 Cm.). The seeds are subglobular, downy, about $\frac{1}{2}$ inch (15 Mm.) in diameter, and consist of albumen, with a central cavity into which the embryo with its five-ribbed cotyledons projects. The bark has a strongly bitter, faintly aromatic taste, and a distinct bitterness is also perceived in the other parts of the plant.

Thomas R. Fraser (1867) has obtained an alkaloid, *akazgine*, which crystallizes from its alcoholic solution, is readily soluble in chloroform, carbon disulphide, benzol, and ordinary ether, is colored brown by concentrated mineral acids, and dissolves in dilute acids, yielding colorless salts, which are rather less persistently bitter than strychnine salts, and are precipitated by the bicarbonates of potassium and sodium; the precipitates occurring with the usual reagents for alkaloids are not crystalline. Heckel and Schlagendaußen (1881) obtained from the drug an alkaloid having the color-reactions of strychnine.

(See also CURARE, p. 530, and IGNATIA, p. 809.)

Off. Prep.—Abstractum nucis vomicæ, Extract. nucis vomicæ fluid., *U. S.*; Extract. nucis vomicæ, Tinct. nucis vomicæ, Strychnina, *U. S.*, *Br.*

Medical Action and Uses.—The action and uses of nux vomica are identical with those of strychnine, and will be treated of in connection with the latter. It may be mentioned in this place, however, that the activity of nux vomica is too variable to render it eligible as a medicine. It may be prescribed in the *dose* of from 1 to 5 grains (Gm. 0.06–0.30) three times a day, and gradually increased from the minimum quantity until its characteristic effects begin to be manifested. The extracts and the tincture are best adapted for its administration.

Dr. Livon has made some experiments upon animals with a bark brought from Thibet, called *hoàng-nân*, and which contains brucine. Its action differs from that of strychnine in producing tetanoid spasms, which commence in the hinder legs of the frogs and dogs employed, and thence extend to the rest of the body. In poisoning by brucine the spinal excitability, it has been alleged, persists several hours after the animal's death, whereas it ceases almost immediately after death caused by the Thibetan poison. But Vulpian (*Les Substances toxiques, etc.*, p. 613) declares that on frogs, at least, the action of *hoàng-nân* is identical with that of strychnine and brucine. The conclusions of this eminent investigator and of Galippe in regard to the preparation as a medicine agree with that we have drawn from the published records concerning it (Lisserteur, 1879; Piffard; Barthélemy, etc.). "The reports of its virtues are, to say the least, greatly exaggerated. As to its use in rabies, one must have an inordinate dose of credulity to believe in it as a cure of this terrible affection." It is also to be borne in mind that *hoàng-nân* is a compound medicine, and that it contains arsenic, which may very well account for its reported efficacy in certain diseases of the skin, and even in leprosy.

AKAZGA.—It appears from the narrative of Prof. Fraser of Edinburgh, who carefully investigated the nature and action of akazga, that it is used as an ordeal in West Africa. "The supposed witch is obliged to drink a certain quantity of the infusion prepared from the bark, and to step over a number of akazga-sticks placed parallel to one another at the distance of 2 feet. If this can be done, the person is pronounced innocent; if guilty, difficulty is experienced in stepping over the sticks; they appear like large logs, to surmount which suitable efforts are made, and these are rendered more and more difficult by spasmodic muscular twitches, until the victim staggers, and ultimately falls in tetanic convulsions. . . . In those cases in which the trial is successfully undergone a copious flow of urine is described as occurring, and by this means the poison is supposed to be removed." The physiological action of the alcoholic extract of akazga, and that of the alkaloid akazgin, correspond to those of nux vomica and strychnine. Each grain of the alkaloid is equal to about 7 grains of the extract or 50 grains of the dried bark in physiological effects, which consist essentially in tetanic convulsions. As yet no therapeutical applications appear to have been made of akazga or its alkaloid.

M'boundou, an African ordeal-poison, was found by Testut to exhibit different modes of action according to its dose, the smaller doses causing convulsive, the larger paralytic, phenomena. He therefore concluded that it contained two principles—the one exciting the reflex function, the other paralyzing it (*Amer. Jour. Phar.*, li. 323). But Heckel and Schlagendaußen inferred that its only active constituent is strychnine, and that it occasions tetanic or paralytic phenomena according to the dose of it administered. Their conclusion agrees with the previous one of Richet (*Bull. de therap.*, c. 223), and is confirmed by the later observations of Vulpian (*Cours de Pathol. exper.*, p. 616), who found in experiments upon frogs that a period of relaxation preceded the convulsive phenomena, often by several hours or even days.

NYMPHÆA.—WATER-LILY.

Pond-lily, E.; *Nénuphar*, *Lune d'eau*, Fr.; *Seerose*, *Wasserlilie*, G.

Nat. Ord.—Nymphæacæ.

Description.—The following species, of which two belong to North America, have been employed:

NYMPHÆA ODORATA, Aiton, *Sweet-scented water-lily*. It has a horizontal immersed rhizome which is 2 or 3 inches (5–8 Cm.) thick, marked on the upper side with broad subcircular or oblong leaf-scars, and on the lower side with the remnants or scars of the thick fleshy rootlets, brown externally, yellowish-white internally, fleshy, with irregular wood-bundles; after drying deeply wrinkled, spongy, and light. It is without odor, and has a bitter mucilaginous somewhat astringent taste. The leaves are large, orbicular-cordate, and entire; the flowers are 4 or 5 inches (10 or 12 Cm.) broad, many-petalous, white, and very fragrant.

NYMPHÆA ALBA, Linné, the European water-lily, resembles the preceding, the chief differences being found in the shape of the fruit and the greater number of its stigmas.

NYMPHÆA ADYENA, Aiton (*Nymphaea Michaux*), *Yellow pond-lily*, *Spatterdock*. The rhizome resembles the above, and is nearly of the same dimensions. The leaves are heart-shaped at the base, with rather divergent lobes, and vary between ovate and roundish in outline. The flowers have six yellow sepals and numerous small yellow petals, which resemble the stamens.

Constituents.—The rhizome of *Nymphaea alba* was examined by Morin (1819) and Carminati, and that of *N. odorata* by Bigelow. Tannin, mucilage, etc. were found, but the bitter principle was not isolated. W. Gruening (*Thesis*, Dorpat, 1881) examined the rhizome and seeds of *Nymphaea alba* and of *Nuphar luteum*, Smith. The principal constituents are tannin and gallic acid, besides starch, gum, resin, albumen, etc. The alkaloids previously observed by Dragendorff were obtained in an amorphous, and probably not entirely pure, condition; that from *Nymphaea* was pale reddish-brown, insoluble in water, and readily soluble in alcohol, ether, and diluted acids; sulphuric acid colors reddish-brown, after the addition of potassium chromate changing slowly to light-green; Fröhde's reagent colors red, then green. *Nupharine* is white, soft above 40° C. (104° F.), easily soluble in alcohol, chloroform, ether, amylic alcohol, acetone, and diluted acids; on heating the solution in diluted sulphuric acid in a steam-bath, it gradually turns brown, and finally blackish-green. The alkaloids appear to be not poisonous.

Medical Action and Uses.—The root of our native pond-lily is astringent and demulcent, and is used internally for the cure of *bowel complaints*, topically in cataplasm for *ulcers*, and in decoction for *leucorrhœa* and *dysentery*. The European species, *N. alba*, was once reputed to be anaphrodisiac, and the juice of the fresh root is said to be acrid, and even capable of reddening the skin. An ointment prepared with it is used to stimulate the scalp when the *hair* tends to fall out.

CENOTHERA.—EVENING PRIMROSE.

Onagre, Fr.; *Nachtkerze*, G.

Cenothera biennis, Linné.

Nat. Ord.—Onagraceæ.

Description.—This very variable plant is common throughout North America in fields and waste places, and has been naturalized in Europe. It has a conical root, which is $\frac{1}{2}$ to 1 inch (12–25 Mm.) thick at the base, 4 to 6 inches (10–15 Cm.) long, with spreading branches, externally pale-brown or sometimes reddish, with a thin bark, internally white, fleshy, inodorous, of a sweetish taste, and in the second year woody and

tough. The *stem* is from 3 to 6 feet (0.9–1.8 M.) high, rough, hairy, often purplish. The *leaves* are alternate, ovate-oblong or oblong-lanceolate, 3 to 5 inches (7–12 Cm.) long, somewhat petiolate, acute, nearly entire, and short-hairy. The *flowers* are in terminal leafy spikes, have a sessile cylindrical ovary united with the long tubular calyx, four obcordate yellow petals, and eight stamens, and produce a four-valved capsule containing numerous seeds. The herb is inodorous and has a mucilaginous and mild astringent taste. The root and the flowering plant are used.

Constituents.—Diot Chicoisneau (1834) found the plant to contain much mucilage; his *anotherin* was a mixture of several bodies, which have not been separated from one another. Braconnot found tannin in the stem.

Medical Action and Uses.—The late Dr. R. E. Griffith, in his *Medical Botany*, after speaking of the mucilaginous and acrid qualities of the herbs and leaves, states that he made use of it in several cases of *infantile eruptions* which had resisted other modes of treatment, and became satisfied that it was highly beneficial—a judgment which his subsequent experience confirmed. It is advised that about the flowering season the small twigs with the bark of the large branches and stem, retaining their leaves, should be dried in the shade. Of these a strong decoction is made, with which the eruptions should be bathed several times a day. We are not acquainted with any later and confirmatory reports upon this plant. It has also been used in *diarrhoea* and in *asthma*.

OLEA DESTILLATA.—VOLATILE OILS.

Olea ætherea s. volatilia, *Ætherolea*.—*Essential (etheral or distilled) oils*, E.; *Huiles volatiles (éthérées, essentielles, distillées)*, *Essences*, Fr.; *Flüchtige (Ätherische) Oele*, G.

Characters.—Volatile oils are those proximate principles to which in the majority of cases the odor of plants is due. They have no chemical, and but few physical, properties in common with the fixed oils, but, like the latter, they are generally soluble in ether, chloroform, bisulphide of carbon, etc., and when dropped upon paper leave a stain resembling that produced by fat, but which, unlike the latter, disappears upon the application of heat. Freshly-prepared volatile oils are generally freely soluble in petroleum benzin, but, according to Belohoubek (1882), after exposure and partial oxidation yield with this solvent a more or less turbid mixture. Their specific gravity usually ranges between 0.85 and 0.99; a few are still lighter, and some are heavier than water, one reaching the specific gravity 1.180. All are inflammable and burn with a bright but very sooty flame. They possess the odor of the plants from which they have been obtained, but are usually less fragrant, which is probably due to the presence in the plants of other odoriferous compounds, perhaps compound ethers, which, being more soluble in water, are removed during the distillation; it is on this account that medicated waters distilled from the drug, almost without exception, possess a more agreeable odor and taste than when prepared from the volatile oil.

When exposed to the air volatile oils become ozonized, and are more or less rapidly converted into a viscid oil or even solid resin; to the presence of ozone is due their bleaching effect upon corks, indigo solution, etc. (See a paper by Dr. J. L. Plummer in *Amer. Jour. Phar.*, 1853, pp. 398 and 508; also, 1860, p. 46.)

Origin.—Volatile oils are met with in a large number of plants, and may exist in every part thereof, from the root to the seed. If found in several parts of the same plant, the volatile oils obtained from them generally differ more or less, not only in odor and other physical properties, but frequently also in chemical composition. They are often separated in the plant in distinct cells, appearing as glands in the herbaceous portion, or distributed throughout the interior tissue, or forming tubes, as in the fruits of the Umbelliferae. Very frequently they are associated with resins, and even exude either naturally or from incisions, holding resins in solution (oleoresins and many gum-resins). In a number of plants they are known to be produced under the action of a ferment, like emulsin and myrosin, upon other compounds, such as amygdalin and myronic acid; but in most cases it has been impossible to demonstrate either the precise tissue where they are produced or the compounds which yield them. There is, however, reason to believe that, at least in some cases, they result from the splitting of glucosides, resins, and similar principles. All volatile oils yield by spontaneous oxidation resinous compounds, which, however, have thus far been found to be entirely distinct from the resins with which the former have been naturally associated.

Among the products of the destructive distillation of organic bodies compounds are often found which possess the general characters of volatile oils, but usually have an empyreumatic odor persistently adhering to them; they are called *empyreumatic volatile oils*. Odorous compounds, sometimes known as *ferment oils* (*fermentolea*), are also produced during the fermentation of bruised vegetables or their expressed juice; they are probably alcohols or compound ethers.

Preparation.—In a few instances, where the volatile oils are separated in cells of the epidermal tissue and not associated with resinous or fatty matters, as in the fruits of many *Aurantiaceæ*, they may be prepared by expressing that tissue after removing it by grating. By far the largest number, however, require to be distilled with water. Herbaceous plants, flowers, and leaves which are not of a leathery nature usually need no previous comminution, but firmer parts of plants, and those containing the volatile oil in the inner tissues, must be more or less ground or broken. Though fresh plants are usually readily softened and permeated by water, a short maceration before the distillation begins is rather advantageous, and may be regarded as very desirable if dried plants are employed; it is unnecessary in case the volatile oils are to be distilled off from resinous compounds; but whenever the volatile oil does not pre-exist, but is produced by the reaction of two principles in the presence of water, a prolonged maceration in cool or lukewarm water is required.

The *distillation* is accomplished in stills made of copper or iron, a sufficient quantity of water being introduced to cover the material and prevent empyreuma; the latter object is more completely attained if a perforated false bottom is placed a few inches above the bottom of the still and the material packed upon it. Direct heat is then applied until the water boils briskly, and is maintained at this temperature until the distillate is no longer charged with volatile oil. Some volatile oils are obtained of better quality and greater fragrance if the direct application of fire to the still is avoided and the volatilization is accomplished by the introduction, near the bottom, of steam under pressure: a wooden tank may then be converted into a still by cutting a suitable aperture in the top and surmounting it with a still-head. Steam distillation is particularly applicable for flowers like those of the orange, lavender, chamomile, etc., and for the labiate and other herbs.

Although volatile oils have a higher boiling-point than water, the majority boiling above 140° C. (284° F.), their vapors diffuse readily in the vapors of water at the boiling temperature of the latter, and are thus easily carried over. Greater difficulty, however, is experienced with those volatile oils which have either an exceptionally high boiling-point or a specific gravity near or exceeding that of water; the addition to the water of about 3 per cent. of table-salt is then advisable, whereby the boiling-point is somewhat raised, and, as the water distils over, it may be gradually increased to about 109.5° C. (229° F.). The volatile oils of cloves, cinnamon, santal-wood, etc. are thus more readily obtained than with water alone.

FIG. 193.

Separator for heavy or light oils.

FIG. 194.

Separating-funnels and Tube-separator.

Cohobation is the returning of the aqueous distillate from which the volatile oil has been separated, either upon the same or upon fresh portions of material, and distilling

again. The process is rendered necessary with cloves, santal-wood, etc., the firm tissue of which, containing the volatile oils, is not easily ruptured or thoroughly permeated by water, and with the petals of rose and similar articles which contain only a minute proportion of volatile oil.

Separation.—On cooling, the distillate separates into two layers, one being a solution of the volatile oil in water, the other the pure oil. A tall cylinder or flask is used, which near the bottom has a glass or other tube inserted and curved upward to a short distance below the top. The heavy water separating at the bottom will commence to discharge through the lateral tube *b* as soon as the vessel is nearly filled with the distillate, upon which will float a layer of volatile oil; this layer may be withdrawn by means of a small siphon, or, better still, through a lateral tube *c* inserted near the top of the vessel. If the volatile oil, however, is heavier than water, the conditions will be reversed, and the oil will flow through *a* and run off at *b*. The last portions of volatile oil are removed from the water by means of a separating-funnel (Fig. 194), the separation being effected with a perforated glass stopper inserted in the neck or by inclining the vessel (Fig. 194) through the tube *a*. For very small quantities a bulb-pipette or syringe-pipette will be found useful, the tube of which is drawn out to a fine point. By a suitable arrangement the separated odorous water may be returned to the still while the distillation is progressing.

If volatile oils are present only in minute quantities, frequent cohobation is required, but even then too much is often lost by being retained in the water, as in the case of violets, tuberoses, etc. To obtain these delicate perfumes, Millon and Commaille (1868) employed purified bisulphide of carbon, with which the material is exhausted, and on the spontaneous evaporation of which all the odoriferous compounds are left behind.

The process of *enfleurage* is likewise adapted for obtaining delicate perfumes: A number of trays or frames are covered with a layer of purified tallow or other inodorous fat, and then with flowers, the latter, if necessary, being replaced by fresh flowers in a few days; when the fat is sufficiently charged with the perfume it constitutes the *pommades* used by perfumers. Liquid fats may be used in a similar manner for extracting such perfumes, the liquid portion of oil of ben being employed, because it resists rancidity for a long time; the *huiles antiques* are obtained in this manner. By digesting the solid or liquid perfumed fat with pure alcohol the odorous principles are taken up by the latter, the spirit then constituting the *extracts* of perfumers; the small portion of fat entering solution separates on exposure to a low temperature.

L. Wolff (1877) proposed a process for preparing volatile oils whereby distillation may either be entirely avoided or materially shortened. Petroleum benzin dissolves from plants chiefly the volatile and fixed oils and wax which are left after evaporating the solvent. The volatile and fixed oils may then be separated either by distillation with water or by agitation with alcohol, removing the fat and wax, and separating the volatile oil from the alcohol by mixing with water.

Rectification is not unfrequently desirable, since resinous compounds and coloring matter may thereby be removed and the odor improved; it is best accomplished by mixing the volatile oil with half of its own weight of an inodorous liquid fat, and distilling the mixture from a solution of table-salt, as stated above.

Composition.—C and H. or C, H, and O, are the elements forming the large majority of the volatile oils; a few (oil of mustard, asafetida, etc.) consist of sulphuretted compounds, and are generally characterized by a disagreeable penetrating odor; some others (oil of bitter almonds, cherry-laurel, etc.) contain hydrocyanic acid, from which, however, they may be freed without otherwise altering their composition or modifying their odor. The first class mentioned, the hydrocarbons, are mostly *terpenes*, consisting of two or more isomeric modifications having the composition of $C_{10}H_{16}$ or a multiple thereof. The oxygenated volatile oils likewise consist proximately of at least two principles, boiling at different temperatures. The one having the lowest boiling-point is called *αropten*, and very often is a hydrocarbon of the composition $C_{10}H_{16}$ or $C_{10}H_{14}$. *Stearopten* is that portion which volatilizes last and congeals at about the ordinary temperature; in composi-

FIG. 195.

tion it is not unfrequently an oxide or hydrate of the hydrocarbon. The stearopten of oil of rose is a hydrocarbon, C_nH_{2n} , and has a lower boiling-point than the fragrant oxygenated portion. Stearoptens—or *camphors*, as they are sometimes called—crystallize from the volatile oils on exposure to a low temperature, the crystallizing-point depending partly on the fusing-point of the stearopten and partly on the amount of the solvent elaepten. The variation in the proportion of the two proximate constituents is due to the influence of climate, soil, and cultivation, and modifies to some extent the effect upon polarized light.

The color of volatile oils appears to be due to distinct compounds. Piesse (1863) separated from oil of wormwood, patchouly, etc. a volatile dark-blue body, *azulene* (according to Gladstone [1863] *corulein*), of the composition $C_{16}H_{26}O$, which he stated to be present in all blue-colored volatile oils, while those having a different color are free from it or contain it in smaller proportion, mixed with more or less of yellow or brown resin.

Preservation.—Since volatile oils oxidize when in contact with air, and the oxidation is accelerated in the light, they should be kept in well-stopped vessels protected from the light. Various contrivances, which readily suggest themselves, have been recommended. Bottles of amber-colored glass, which excludes the actinic rays, are very suitable; and the addition of a small quantity of alcohol, which in our experience need not exceed 3 per cent., will prevent for a long time, if not the oxidation, at least the marked change of odor, which oils of orange, lemon, peppermint, and others undergo. Menigaut as early as 1835 proposed for the same purpose the addition of an equal weight of alcohol.

Restoration.—Resinified volatile oils, the flavor of which has not been impaired, may be restored to their former limpidity by rectification (see above). Small quantities of such volatile oils Curieux (1858) recommended to be agitated for fifteen or twenty minutes with a magma formed by mixing solution of borax with animal charcoal, when the resinified portion will unite with the borax, leaving the oil limpid and the odor restored.

Adulterations.—Among the numerous methods which have been recommended for detecting the principal adulterations to which volatile oils are subject, the following are simple, reliable, and easily executed:

(a) *Fixed oils* are indicated by the permanent greasy stain left upon paper or by the residue left on distilling the suspected oil with water. Since the fats are mostly insoluble, and the volatile oils mostly soluble in 85 per cent. alcohol, this solvent will leave the former behind; minute quantities of fixed oils, however, will escape detection by this method.

(b) *Alcohol* will cause a diminution of the volume of the volatile oil when this is agitated with an equal bulk of water or glycerin in a graduated tube; the difference indicates approximately the amount of the adulteration. If olive oil is used in place of water, the alcohol, unless present in a very small quantity, will separate. Fused calcium chloride and dry acetate of potassium are insoluble in volatile oils, but in the presence of alcohol become either soft or liquid. Tannin, which has been recommended for the same purpose, is soluble in oil of bitter almonds, cinnamon, and a few others. Dragendorff recommends metallic sodium, which produces a brisk evolution of gas in the presence of even 5 or 10 per cent. of alcohol, while hydrocarbons are not at all, and oxygenated oils but slightly, acted on in the cold. Aniline-red is soluble in alcohol and insoluble in volatile oils, but if the oils contain alcohol they are colored red by the dry aniline color.

(c) *Cheap volatile oils* are often difficult to detect. On rubbing a few drops of the volatile oil between the hands, or heating them gradually in a dish, or evaporating them from bibulous paper, and observing the odor from time to time, a marked difference of it is indicative of such adulteration. The hydrocarbons being mostly cheaper and less freely soluble in 85 per cent. alcohol than the oxygenated oils, an adulteration with the former will generally be recognized by the solvent mentioned.

The solubility of santal-red in some volatile oils (Voget), the different reaction of these oils with iodine (Tuchen), the change of color produced on heating oxygenated volatile oils with a little nitro-prusside of copper, and the prevention of this reaction by oil of turpentine and other hydrocarbons (Heppé, 1856), and the behavior of the volatile oils toward strong mineral acids, potassa, bromine, sulphide of lead, and other chemicals.—may, at least occasionally, be utilized for the purpose of detecting adulterations. (See *Proceedings Amer. Phar. Assoc.*, 1858, p. 344, and 1859, p. 338.)

OLEA PINGUIA.—FIXED OILS.

Fats, Fatty oils, E.; Huiles grasses, Huiles fixes, Fr.; Fette, Fette Öle, G.

Characters.—Fats are peculiar compounds obtained both from the animal and the vegetable kingdom. In their pure state they are often colorless, inodorous, and tasteless. Many are liquid at the ordinary temperature (*oils* or *fixed oils* proper), but by cautious cooling may generally be separated into fats of different fusibility. Others have a soft consistence (*fats* proper, or *butters*), and mostly yield liquid fats when subjected to a gradually increased pressure, while a fat of a higher fusing-point remains in the press-cloth. Those of a firmer consistence are sometimes termed *tallows*, and when hard and more or less brittle at the common temperature they are often popularly and commercially known as *waxes*. They are all lighter than water, and vary in specific gravity generally between .913 and .956, though some are as light as .860. They are insoluble in water, sparingly soluble in cold alcohol, but generally freely soluble in ether, chloroform, carbon disulphide, benzol, and light petroleum oils. The hot alcoholic solution of the solid fats separates them on cooling, generally in a crystalline form. When heated, the solid fats fuse to transparent oils and solidify again on cooling. Heintz observed that by raising the heat very slowly some fats show two fusing-points, which for pure stearin were found at 55° C. (131° F.) and 71.6° C. (160.9° F.), and also two congealing-points, the latter depending upon the temperature to which the fat had been heated and upon the rapidity with which it had cooled. After having been heated considerably beyond the fusing-point some solid fats remain liquid for a long time after cooling; at a higher temperature, usually in the neighborhood of 300° C. (572° F.), an ebullition is observed, accompanied by decomposition, the boiling-point gradually rises, and extremely acrid and irritating vapors are evolved, causing a copious flow of tears, and containing *acrolein*. (See GLYCERIN, p. 735.)

Fats are more or less unctuous to the touch, and when in a liquid condition dropped upon paper leave a permanent grease-spot unless they are crystalline and so hard that they may be rubbed off. They are not inflammable at the ordinary temperature, but when heated to incipient decomposition burn more or less readily by the aid of wick and with a sooty flame. When their surface is considerably increased by being spread over porous bodies they are rapidly oxidized, whereby the heat may be increased to such an extent as to ignite the entire mass.

Origin.—All plants, and perhaps all parts of plants, contain fat, though often in minute quantity. The liquid and solid fats are most likely generated from starch and other carbohydrates and allied compounds; De Luca (1862) proved that the fixed oil of olives increases in quantity as the mannit of the green olives disappears, and that the access of air and light facilitates the conversion. It is not unlikely that certain protein compounds may likewise be the source of fats. In the animal economy fats are, at least partly, produced in a similar manner.

Preparation.—From animal tissues rich in fat the latter is obtained by fusion either by itself or in the presence of water, and removal of the tissue by skimming or straining. Vegetable tissues containing notable quantities of fat yield it on being subjected to powerful pressure, either at the ordinary temperature or between plates which are heated to a little beyond the fusing-point of the fat; but since a certain quantity of the fat is mechanically retained by the tissues, a larger yield is had by the use of a solvent, such as carbon disulphide or petroleum benzin, which on being distilled off leaves the fat behind. When the bruised or cut vegetables are boiled with water, the fused fat rises to the surface, and may either be skimmed off or obtained by straining, expression, and subsequent separation from the water; such fats are usually inferior to those obtained from the dried article by pressure alone.

Purification.—The impurities contained in fats are protein and mucilaginous compounds derived from the vegetable tissue, and may be removed through a well-dried filter; the filtration is facilitated by a somewhat elevated temperature. An apparatus suitable for this purpose, and for filtering through flannel in an upward direction and under pressure of a column of the oil, was constructed by W. R. Warner (1861): A is the reservoir containing the oil; B, the recipient of the filtered oil. On the large scale the purification is effected by the gradual addition to the oil of $\frac{1}{2}$ to 2 per cent. of sulphuric acid, whereby the impurities are carbonized; the oil is then agitated with water to remove adhering acid, decanted, and often filtered through charcoal, or through tow, moss, or similar material, upward filtration being preferred. The use of sulphuric acid for the

purification of oils was introduced in England by Gowen (1796). Chloride of zinc has a similar effect, according to R. Wagner, if used in concentrated solution, 1 to 1½ per cent. being required; and Barreswil (1858) recommended for the same purpose the saponification

FIG. 196.

Warner's Oil-Filter.

of a small proportion of the fat by means of a weak solution of potassa or soda. From 1 to 2 per cent. of ammonia will often be effectual, and as mechanical agents for separating the impurities powdered clay and plaster of Paris have been found to serve a good purpose. The loss sustained in purification varies with the nature and amount of the impurities, and in some cases reaches 15 or 20 per cent. of the crude oil.

Bleaching.—The treatment of fats with sulphuric acid usually destroys also the coloring matter wholly or in part; treatment with animal charcoal renders the fats lighter, and many are bleached (and often become rancid) by exposure to the direct sunlight, a strip of lead being sometimes introduced into the fat if liquid, or this is occasionally agitated with an aqueous solution of ferrous sulphate. Palm oil is bleached by being rapidly heated to 240° C. (464° F.) and keeping it at this temperature for 10 minutes. The same effect is produced upon oil of poppy-seed by heating it for 5 hours to between 90° and 95° C. (194° and 203° F.). Oxidation of the coloring principle by means of permanganic or chromic acid or hypochlorites has likewise been recommended.

Composition.—Nearly all animal and vegetable fats are mixtures of two or more fats having a different fusing-point; those which are liquid at the ordinary temperature separate in the cold granular masses of the solid fats contained in them, while those which are solid at the common temperature often yield by expression a liquid oil. With comparatively few exceptions, fats are compound ethers of the triatomic alcohol glycerin (see page 734), and the acids contained in them belong to two series, the fatty acid group of the general formula $C_nH_{2n}O_2$, and the oleic acid group of the formula $C_nH_{2n-2}O_2$. The most important

members of the first group are stearic ($C_{18}H_{36}O_2$), palmitic ($C_{16}H_{32}O_2$), myristic ($C_{14}H_{28}O_2$), lauric ($C_{12}H_{24}O_2$), and butyric ($C_4H_8O_2$) acids. To the second group belong, besides oleic acid ($C_{18}H_{34}O_2$), erucic ($C_{22}H_{42}O_2$) and hypogæic ($C_{16}H_{30}O_2$) acids, the former being found in oil of mustard, the latter in oil of ground-nut. All these acids are monobasic, and the neutral fats therefore contain 3 molecules of the acid to 1 of the other radical, C_3H_5 ; these compounds are conveniently named from the acid by changing the termination to *in*; thus *stearin* or *tristearin* is $C_3H_5 \cdot (C_{18}H_{36}O_2)_3$, and *olein* or *triolein* has the formula $C_3H_5 \cdot (C_{18}H_{34}O_2)_3$. The fats most widely distributed are olein, stearin, palmitin, myristin, and laurin, which are inodorous when pure, while the fats of the volatile acids have a distinct odor, the most important being *butyrin*. Fats which on exposure to air gradually solidify through the absorption of oxygen, the so-called *drying oils*, are supposed to contain *olin*, the composition of which is not known; the drying fat of linseed oil has been named *linolein*.

The fusing-points of the above-named pure fats are as follows: Stearin, 55° C. (131° F.); palmitin, 48° C. (118.4° F.); myristin, 31° C. (87.8° F.); laurin, 44° C. (111.2° F.). The margarin of older chemists is a mixture of palmitin and stearin; olein and butyrin are liquid at common temperatures.

Preservation.—Fats should be kept in a dry place at a low temperature, and protected from light and air. On being exposed to the atmosphere the fats gradually become rancid, and this change is accelerated by the presence of animal and vegetable tissue, protein, and mucilaginous compounds; hence the importance of careful purification. The rancidity is due to the generation of odorous compounds, perhaps some acrolein and volatile fatty acids, besides some coloring matter. Rancid fats may be improved, and to a certain extent restored, by washing with warm water or by treating them with magnesia or other weak alkali, and afterward washing them well. Treatment with strong alcohol or agitation of the oil with a little powdered borax and exsiccated sodium carbonate has likewise been recommended.

Adulterations.—The higher-priced fats are not unfrequently adulterated with cheaper ones, and, owing to the similarity of composition, such admixtures are difficult

to recognize. A change of the fusing-point in the solid and of the congealing-point in the liquid fats is not unfrequently produced by addition of other fats, and other criteria are afforded by the color, consistence, odor, and taste, sometimes also by the specific gravity. The non-drying oils when subjected to the influence of nitrous acid become solid, the olein being converted into the solid isomeric compound *claidin*, which fuses between 25° and 28° C. (77° and 82° F.), and solidifies again on cooling. The test is made by agitating for a short time 1 part of copper in small pieces with about 5 parts each of nitric acid and the oil, and setting the mixture aside; the separation of claidin commences in about an hour, and the solidification is generally completed in about 6 hours. Almond oil and olive oil are scarcely colored thereby, but become opaque; the drying oils (linseed, poppy-seed, hemp-seed, and nut oils) remain liquid, while the following become thicker, but not solid: castor, cotton-seed, sunflower-seed, and benne-seed oil, the latter acquiring also a red color.

On carefully placing a drop of oil or oleoresin upon the surface of chemically pure water contained in a perfectly clean glass vessel, distinct figures are formed, which were termed *cohesion-figures* by C. Tomlinson (1864), and which have a distinct character for the different liquids. These cohesion-figures have been recommended as a means of identifying the liquids, and possibly also of determining the presence of admixtures.

The character of the soda soap may likewise serve to indicate an adulteration with drying oils; for this purpose the oil is agitated with one-third of its weight or more of soda solution, specific gravity 1.33 (containing 30 per cent. NaHO), and the mixture boiled until saponification has been effected; after cooling, the soap of the drying oils will be soft, and should oils of Cruciferae (mustard, etc.) have been present, the aqueous filtrate will impart a black color to paper moistened with solution of lead acetate, owing to the sulphur present in the oil. The melting-point of the mixed fatty acids separated from the soap by hydrochloric acid has been suggested by O. Bach (1883) as a means for recognizing the purity of the fats; the results with the acids were as follows:

From cotton-seed oil, melting at 38° C.,		congealing at 35° C.;	
"	sesame oil, " " 35° C.,	"	" 32.5° C.;
"	ground-nut oil, " " 33° C.,	"	" 31° C.;
"	olive oil, " " 26.5°-28.5° C.,	"	" 22° C.;
"	sunflower oil, " " 23° C.,	"	" 17° C.;
"	rape-seed oil, " " 20.7° C.,	"	" 15° C.;
"	castor oil, " " 13° C.,	"	" 2° C.

Concentrated sulphuric acid produces with different fixed oils mixtures varying in color: 8 or 10 drops of the oil are placed upon a china plate, 2 or 3 drops of sulphuric acid are added, and after a few seconds mixed by stirring; the color of the mixture will be as follows: with *almond oil*, yellow, changing to pale brownish-yellow; with *olive oil*, yellow, turning brownish; with *lard oil*, yellow and brown; with *cotton-seed oil*, yellow and brown; with *ground-nut oil*, yellow and green-brown; with *benne oil*, brown-red, becoming gelatinous; with *sunflower oil*, red-brown and brown; with *hemp-seed oil*, brown, black, and solid; with *linseed oil*, brown-red to blackish-brown; with *rape-seed oil*, greenish-blue or brownish-green; with *poppy-seed oil*, yellow to brownish-green; with *castor oil*, brownish to gray-brown. When larger quantities of oil are mixed with sulphuric acid a rise of temperature takes place, which is not alike for different oils. According to Behrens (1852), when a cold mixture of equal parts of nitric and sulphuric acid is added to an equal weight of oil, *benne oil* acquires a green, *ground-nut oil* a red, and *olive oil* a yellow color. (See also OL. AMYGDAL. EXPRESS.)

The effect of nitric acid upon the oils depends not only upon the composition of the latter, the presence of coloring matter, etc., but likewise upon the strength of the acid and the temperature. Bach (1883) recommends testing the oils by agitating for 1 minute 5 Ccm. each of oil and nitric acid; the test-tube is afterward placed in boiling water for 5 minutes, and finally set aside for 18 hours at about 15° C.; the results obtained were, with—

Olive oil,	cold, pale-green;	hot, orange-yellow;	final result, solid.
Cotton-seed oil,	" yellowish-brown;	" reddish-brown;	" " butyraceous.
Sesame oil,	" white;	" brownish-yellow;	" " liquid.
Ground-nut oil,	" pale rose-color;	" brownish-yellow;	" " solid.
Sunflower oil,	" dingy-white;	" reddish-yellow.	
Rape-seed oil,	" pale rose-color;	" orange-yellow;	" " solid.
Castor oil,	" pale rose-color;	" golden-yellow;	" " butyraceous.

Lipowitz (1868) observed that the admixture of drying in non-drying oils may be

detected by triturating 8 parts of the oil with 1 part of chlorinated lime; in the course of a few hours the mixture, if made with non-drying oils, will separate a layer of limpid oil, while no oily layer will separate from the mixture containing a drying oil. This appears to be due to the rapid oxidation of the latter.

Since most of the fats are without action upon it, polarized light does not afford a means of distinguishing them; of the officinal oils, only castor oil has a decided rotation to the right.

OLEANDER.—OLEANDER.

Laurier rose, Laurose, Fr.; Oleander, Rosenlorbeer, G.

The leaves of *Nerium Oleander*, *Linne*.

Nat. Ord.—Apocynaceæ.

Origin.—This well-known ornamental shrub grows wild in Southern Europe, Northern Africa, and Western Asia, and thrives best in moist ground. It is 10 to 15 feet (3–4.5 M.) high, often arborescent, with a gray or greenish-gray nearly smooth bark, ternately-divided branches, and showy dark rose-colored or white flowers. All parts are reputed to possess poisonous properties.

Description.—The leaves are whorled in threes, leathery, smooth, dark-green and glossy above, nearly sessile, linear-lanceolate, 4 to 6 inches (10–15 (in.) long, finely pointed at the apex, entire on the margin, and delicately feather-veined. They are without odor and have a nauseous and bitter taste.

Constituents.—Lukowski (1861) obtained two alkaloids from the leaves and branches by carefully precipitating their decoction with tannin; the tannate of pseudocurarine is soluble in an excess of tannin, and the alkaloid liberated by oxide of lead. *Pseudocurarine* is amorphous, yellowish, tasteless, and inodorous, insoluble in ether, freely soluble in water and alcohol, and yields uncrystallizable salts. *Oleandrine* is a yellowish resinous body, slightly soluble in water, very soluble in alcohol, chloroform, and ether, of a strongly bitter taste, and poisonous. Its salts are uncrystallizable. Bitteli (1875) observed that oleandrine loses its poisonous properties when heated to 240° C. (464° F.), and that the hydrochlorate is crystalline; he regards the pseudocurarine as a mixture of different principles containing a little oleandrine. Schmiedeberg (1882) ascribes the poisonous action to oleandrine, while a second principle, *neriantin*, is stated to be a glucoside and to possess only a feeble action. Pelikan (1866) considered the poisonous principle to be a yellow acrid resin, which, according to Latour (1857), possesses acid properties. The latter chemist determined also the presence of tannin, fat, and other common principles.

Allied Plants.—*NERIUM ODORUM*, *Aiton* (*N. odoratum*, *Lamarch*). It is indigenous to and cultivated in India, and resembles the oleander, but has longer leaves and fragrant flowers with a fringed paracorolla. The bark somewhat resembles mezereon-bark, but breaks with a short fracture. Examined by H. G. Greenish (1881), fixed oil was obtained, and two bitter poisonous glucosides, both of which are insoluble in benzol, benzol, and carbon disulphide. *Neriodorin* is a transparent yellow tenacious mass, readily soluble in chloroform, colored deep reddish-brown by ferric chloride, and precipitated by basic lead acetate and by potassio-mercuric iodide. *Neriodorcin* is a lemon-yellow powder, insoluble in chloroform, colored slightly brown by ferric acetate, and not precipitated by potassio-mercuric iodide nor by basic lead acetate until a little ammonia has been added.

THEVETIA YCCOTLI. *De Candolle* (*Cerbera thevetioides*, *Kunth*), is an elegant tree with dark-green foliage and golden-colored flowers, indigenous to the damp hot regions of the Mexican Cordilleras, where it is known as *joyote*. It bears an ovoid-globular crested and laticiferous drupe containing four (or by abortion two) seeds, which have a thin papery testa, a reticulate tegmen, two orbicular, unequal, crested cotyledons, and a short conical radicle. The joyote-seeds are extremely acrid, and, according to Herrera (1877), yielded by pressure 40 per cent. of oil resembling almond oil. The expressed seeds yielded to ether more oil, to distilled water albuminous and extractive matter, and to alcohol a crystalline acrid principle, *thevetosin*, which is sparingly soluble in ether, carbon bisulphide, and fixed and volatile oils, is insoluble in water, and on being treated with dilute nitric acid is split into glucose and a resinoid substance.

THEVETIA (*Cerbera*, *Kunth*) *CUNEIFOLIA* and *TH. OVATA*, *De Candolle*, are likewise known as *joyote* and as *narcisos amarillos*, and probably possess similar properties.

THEV. NERIIFOLIA, *De Candolle* (*Cerbera Thevetia*, *Linne*), is a West Indian shrub, the bark of which is used as an anti-periodic.

GEISSOSPERMUM LEVE, *Baillon*, known in Brazil as *paó pereira*, is a tree the intensely bitter bark of which has been much used in that country. Santos (1838) separated from it an alkaloid, *pereirine*, which in its impure state, as a brown-yellow amorphous powder, is employed in Brazil. Bochefontaine and De Freitas (1877) proposed to call it *geissospermine*, and Hesse (1877) adopted

this name for the alkaloid, which is nearly insoluble in ether and water and readily soluble in alcohol and dilute acids; it crystallizes in small white prisms, dissolves in strong nitric acid with a purple-red color, becoming orange-yellow on heating, and in concentrated sulphuric acid at first colorless, rapidly changing to blue, and gradually to a pale color: its composition is $C_{19}H_{21}N_2O_2 \cdot H_2O$. A second alkaloid, *perceirine*, is easily soluble in ether, forms a grayish-white amorphous powder, and is colored blood-red by nitric and violet-red by sulphuric acid; it appears to be present in larger proportion than the preceding one. The leaves of this tree, which were sent to Europe as *caroba-leaves*, have also a bitter taste, and probably contain the same alkaloids.

STROPHANTES HISPIDUS, *De Candolle*. The plant, called *inée*, is indigenous to tropical Africa, where the seeds are used in the preparation of an arrow-poison. Hardy and Gallois (1877) isolated from the seed the poisonous neutral principle *strophantin*, which forms white crystals and is soluble in water and slightly soluble in alcohol and chloroform. The hairy seed-crown contains *ineine*, a non-poisonous crystalline alkaloid.

Physiological Action.—According to Kurzak, the leaves, flowers, bark, and wood of oleander are poisonous. Their action was studied by Orfila and by himself. The effects of an extract upon rabbits, birds, and frogs consisted essentially of paralysis of the voluntary and involuntary muscles, including the heart, the former muscles being from time to time convulsed, and death occurred from arrest of the respiration, and then of the heart. After death the heart was flaccid, and it and also the large veins were distended with dark blood. Several fatal cases of poisoning in man have been traced to this plant, and two at least to eating birds that had devoured its berries. In the south of Europe the bark is said to be used as a rat-poison and a decoction of the leaves to destroy lice. Domestic animals have been poisoned by drinking water in which oleander-leaves had been soaking. According to Landerer, the essential oil irritates the skin (Husemann, *Toxicologie*, p. 503). According to Schmiedeberg, the leaves of oleander contain two chemically different, non-nitrogenous constituents—neriine and oleandrine—which agree, however, in their action. The former is said to be identical with the “digitalin” of digitalis (*Centr. bl. f. d. g. Therapie*, i. 299). Thevetine and theveresin have been thoroughly tested in experiments on animals by Blas and by T. Husemann (*Archiv für exp. Pathol. u. Phar.*, v. 228). The former has upon frogs the same effects as digitalin, and its lethal dose is also nearly the same (Gm. 0.001–0.003). It first hurries the respiration and renders it irregular, and kills by producing a tonic contraction of the ventricle of the heart, with a corresponding engorgement of the auricle and of the general circulation. Voluntary motion is not destroyed, although motility is impaired in the hind legs. The same effects, essentially, were produced by theveresin in the dose of Gm. 0.05. Experiments upon dogs and rabbits led these observers to recognize a strong analogy between the effects of these glucosides and the effects of digitalin, helleborin, and other analogous products. They produce repeated attacks of vomiting (in dogs), and sometimes watery diarrhœa and profuse salivation, with extreme prostration, so that the animal lies still and will not change his posture except during the efforts at vomiting. The cerebral functions seem to be impaired, at least at the beginning of the attack; later, when exhaustion has become complete, the animal remains motionless, as if narcotized. The breathing is labored, but the pupils are unchanged, and muscular tremor is constant, although spasms are either absent or only occur just before death. As above stated, in animals killed by these poisons the ventricle is contracted, yet in exceptional cases it is found dilated with dark blood. The vomiting produced by thevetin is doubtless due in part to its irritant qualities, for when it is injected hypodermically the punctures are apt to produce abscesses. The venous congestion of the stomach, which gives the interior of the organ a blue color, is partly due to the cardiac obstruction and partly to the repeated efforts at vomiting. According to Prof. Carpio (*Phil. Med. Times*, ix. 396), the thevetin of Thevetia peruviana produces symptoms almost identical with those above described, and kills by arresting the heart either in diastole or in systole. The experiments of Cerna (*Ibid.*, p. 426) led him to the following among other conclusions: Thevetin produces death by asphyxia and by cardiac paralysis; applied to the skin, it irritates, with a sensation of burning; it produces convulsions of cerebral and paralysis of spinal origin; increases intestinal paralysis; lowers the temperature; locally applied, it contracts the pupil; and it increases salivation. Warden has confirmed the statement as to the production of convulsions (*Amer. Jour. Phar.*, liv. 301).

Decourtilz, in his *Flora of the Antilles*, speaks of *T. neriifolia* as an acrid poison, of the bark as a drastic purgative, of the fruit as emetic, and of an extract of the plant as a remedy for intermittent fever. He describes the case of a young negro who had eaten of the green fruit, and who was affected with chills, delirium, and other nervous symptoms, nausea, and a thready pulse; he had irregular spasms, followed by extreme agita-

tion, with singing, laughing, and weeping, and then by a fixed blank look. He seemed tending to coma, but was relieved by an emetic. In 1857, Balfour and MacLagan published a narrative of two children poisoned by the seeds of the same plant. Presently there occurred drowsiness, interrupted every few minutes by the discharge of a quantity of frothy mucus from the mouth, by vomiting also, and diarrhœa. The skin was cool and moist, the pulse slightly slower than natural and rather weak. The vomiting was performed without straining and by regurgitation. It is worthy of notice that one of the children who had been suffering from intermittent fever had no return of the paroxysms.

The following conclusions were drawn by Bochefontaine and De Freitas from experiments on guinea-pigs and dogs with the watery and also the alcoholic extract of the bark of *G. lœve*, and with geissospermine used hypodermically: 1. Geissospermine is not a local irritant, or is feebly so. 2. It is poisonous. 2 Mgm. of it are fatal to a frog, and half a Mgm. paralyzes the animal. 1 Cgm. will kill a guinea-pig weighing 668 Gm., but no less than fourteen times this quantity are necessary to paralyze a small dog. 3. In several experiments it slowed the heart's action and the respiration, and diminished the arterial blood-pressure. 4. Its first effect was to lessen voluntary motion, the animals being at the same time inert and insensible, although the reflex movements were not prevented, but at first suspended. 5. Subsequently reflex motility was destroyed. Hence the drug expends its power primarily upon the motor centres of the brain, and subsequently on those of the spinal cord. 6. The sensory nerves appear to retain their function as long as the motor nerves. When the main artery of a frog's hind leg is tied, and the poison is given hypodermically in a fore leg, the limb protected by the ligature and the free hind limb equally lose reflex irritability. 7. This excitability becomes extinct only after the animal has been for some time torpid and inert. 8. Muscular contractility is not affected by geissospermine. Hence it may be inferred that the active principle of this plant is capable of "abolishing the physiological functions of the central gray nervous substance, and particularly of the gray axis of the bulb and the spinal cord."

Medical Action and Uses.—Oleander is one of the plants whose flowers are said to render honey poisonous, and the experiments described above seem to show that its active principle is a heart-poison. It has been used in *epilepsy*, but fruitlessly.

OLEATA.—OLEATES.

Oléates, Oléés, Fr.; Oleate, G.

This class of preparations was first proposed by Lhermite (*Jour. Phar. Chimie*, Oct., 1854, p. 301) but did not attract attention until recommended by Prof. John Marshall (1872). They are made from oleic acid by combining with it metallic bases or alkaloids, nearly all of which dissolve easily in the acid on trituration in a mortar. The application of a high heat should be avoided, since oleic acid is very readily altered by it and some of the metallic oxides are reduced. The medicinally employed oleates are solutions of oleates in an excess of oleic acid.

The preparation of mercuric oleate by double decomposition was recommended by Louis Dohme (1873), who combined oleic acid with potassa and precipitated the soap solution with mercuric nitrate. Subsequently, Van Harlingen (1873) proposed decomposing a solution of soap, made of almond oil, with a soluble salt of mercury, zinc, or other metal. These precipitates, like those obtained with good Castile soap, are mixtures of oleates with palmitates. But Dr. L. Wolff (1881) observed that if a solution of 1 part of Castile soap in 8 parts of hot water be set aside in a cool place for 24 hours, much of the sodium palmitate will be deposited, and the clear solution will yield with salts of metals precipitates, from which the oleates will be dissolved by benzin, in which the palmitates are insoluble or nearly so.

OLEATUM ACONITINÆ. Oleate of aconitine, is made by dissolving 2 grains of the alkaloid in 98 grains of oleic acid.

OLEATUM ATROPINÆ and **OLEATUM STRYCHNINÆ** are made of the same strength, representing 2 per cent. of the alkaloids.

OLEATUM MORPHINÆ. Oleate of morphine, is prepared by dissolving 5 grains of the alkaloid in 95 grains of oleic acid. It soon grows darker in color, but retains its efficacy, at least in part.

OLEATUM QUININÆ. Oleate of quinine, is made by dissolving 25 grains of the dry alkaloid in 75 grains of oleic acid.

OLEATUM PLUMBI. Oleate of lead, containing 20 per cent. of oxide, is readily made by digesting at a temperature of about 65° C. (149° F.), and is a yellowish tenacious ointment.

OLEATUM ZINCI. Dr. Squibb recommends it to be made with 5 per cent. of zinc oxide, when it is a soft solid. Made with 20 per cent. of oxide, according to A. W. Gerard (1872), it is hard and friable, but transparent when melted; this contains an excess of zinc oxide. The *Br. P.* directs oxide of zinc 1 ounce, oleic acid 9 ounces.

Oleopalmitate of zinc is whitish, pulverulent, somewhat resembling powdered soapstone. *Oleopalmitate of bismuth* has an unctuous consistence. *Oleopalmitate of copper* has a blue-green color.

OLEATUM HYDRARGYRI, *U. S.*, *Br.*—OLEATE OF MERCURY.

Hydrargyrum oleicum, s. *oleïnicum*, s. *elaïnicum*.—*Mercuric oleate*, *E.*; *Oléate mercurique*, *Fr.*; *Quecksilberoleat*, *Mercurioleat*, *G.*

Preparation.—Yellow Oxide of Mercury, thoroughly dried, 10 parts (10 grains); Oleic Acid 90 parts (90 grains); to make 100 parts (100 grains or about 2 fluidrachms). Heat the oleic acid, contained in a porcelain vessel, to near 74° C. (165.2° F.), taking care not to exceed this temperature. Gradually add the oxide of mercury and stir until it is dissolved.—*U. S.*

Made with nearly pure oleic acid, it is a thick yellowish liquid, which will keep unaltered for a long time unless too high a heat has been employed; but if made with crude commercial oleic acid, containing much palmitic acid, it is of an unctuous consistence and gradually deposits some metallic mercury. The *Br. P.* directs trituration without heat.

Medical Action and Uses.—Oleate of mercury was proposed and introduced by Marshall (1872) for making an ointment more cleanly and at the same time more efficient than mercurial ointment, because more readily absorbed after its mere application to the integument without friction. It, however, was liable to the objection of irritating the skin in many cases unless it was diluted with olive oil or lard. In order to proportion the strength of the preparation to the different degrees of susceptibility of the skin, it contained different percentages of the oxide of mercury, from 3 up to 20 per cent., and as the stronger were apt to produce pain, 1 grain of morphia was combined with each drachm of the preparation. It was painted on the affected part with a brush or mop, and not rubbed in like ordinary liniments or embrocations.

It was originally applied to *joints* affected with *chronic inflammations*, synovial or rheumatic; to indurations of the *mammæ* and *lymphatic glands*; to the pustules of *sycosis*; to the seat of itching in *pruritus pudendi et ani*; and to destroy *lice* infesting the genitals. A mass as large as a pea or bean of the 20 per cent. oleate was placed in the child's axilla in cases of congenital *syphilis*; the application, repeated night and morning for 5 or 6 days, produced its constitutional effects without any sign of uncleanness. In the non-ulcerated forms of *syphiloderma* affecting the face, neck, or hands the 10 per cent. solution was found a valuable adjunct to their treatment. This solution was also applied to non-ulcerated indurations and *condylomata*, to the eyelids in *syphilitic iritis*, and to hard *nodes* and certain forms of *syphilitic testicle*. It is alleged to have cured bromidrosis, or *fetid sweating* of the axilla (*Lancet*, May 8, 1880). Most of these results were soon after their announcement confirmed (Hill, Martini, 1873), but not those relating to non-syphilitic inflammatory affections. With the exception of a suggestion that it would form an excellent substitute for the ointment of yellow oxide of mercury in the treatment of diseases of the eye (1878), there does not appear to have been any other account published of this preparation, from which it may be inferred that experience has not confirmed the estimate of its value entertained by its proposer.

OLEATUM VERATRINÆ, *U. S.*—OLEATE OF VERATRINE.

Veratrinum oleicum.—*Oléate de vératrine*, *Fr.*; *Veratrinoleat*, *G.*

Preparation.—Veratrine 2 parts (2 grains); Oleic Acid 98 parts (98 grains); to make 100 parts (100 grains or about 2 fluidrachms). Rub the veratrine with a small quantity of the oleic acid in a warm mortar to a smooth paste. Add this to the remainder of the oleic acid, heated in a porcelain capsule on a water-bath, and stir until it is dissolved.—*U. S.*

Action and Uses.—This preparation contains half as much of the alkaloid as veratrine ointment. Like that compound, it is useful as an application to neuralgic centres. It should be applied with a mop.

OLEORESINÆ.—OLEORESINS.

Oléo-résines, Extraits étherés, Fr.; Elharze, Atherische Extrakte, G.

These preparations consist mainly of fixed or volatile oils associated with resin and some other constituents, and are directed to be prepared by exhausting the powdered

FIG. 197.

Percolator, with still and condenser, for preparing oleoresins.

drug with ether. The great volatility of this solvent renders it necessary to percolate in a well-closed apparatus, in which the pressure is equalized by connecting the receiving vessel with the top of the percolator by means of a tube (see page 607). The ethereal tincture is afterward transferred to a suitable still, and the ether distilled off from a water-bath with a moderate heat. Various apparatuses have been constructed to accomplish the exhaustion with the smallest possible quantity of ether by using the same liquid over again until the material has been exhausted; for this purpose the recipient is placed in water of about 50° C. (122° F.); the ether vapors ascending through the connecting tube mentioned above are condensed in a suitable refrigerator, and the ether is again passed into the percolator, the operation being repeated as often as required. The annexed cut, taken from Parrish's *Pharmacy*, represents such an apparatus, which is best made of tinned sheet iron, or preferably of copper well tinned on the inside; it explains itself, and it is merely necessary to state that the head is perforated at the bottom for the equal distribution of the menstruum, and jacketed above for the condensation of the ether. The percolator being likewise jacketed, it may be immersed in warm water, and the ether recovered which remains in the powder after exhaustion; or, if distillation be inconvenient, the greater portion of the ether may be displaced by means of alcohol.

If the operation has been carefully conducted, the ether thus regained is not at all or but very slightly impregnated with volatile oil; nevertheless, it must be regarded as unfit for internal use, and should be reserved for a similar subsequent operation.

OLEORESINA ASPIDIJ, U. S.—OLEORESIN OF ASPIDIUM.

Oleoresina filicis, U. S. 1870; *Extractum filicis liquidum*, Br.; *Extractum filicis*, P. G.; *Oleum filicis maris*.—*Oleoresin* or *Liquid extract of male fern*, E.; *Extrait étheré (Huile) de fougère mâle*, Fr.; *Wurmfarnextrakt, Wurmfaröl, G.*

Preparation.—Aspidium, in No. 60 powder, 100 parts (10 oz. av.); Stronger Ether a sufficient quantity. Put the aspidium into a cylindrical glass percolator provided with a stopcock and arranged with a cover and receptacle suitable for volatile liquids; press it firmly, and gradually pour stronger ether upon it until 150 parts (15 oz. av. or about 18 fluidounces) of liquid have slowly passed. Recover the greater part of the ether by distillation on a water-bath, and expose the residue in a capsule until the remaining ether has evaporated. Keep the oleoresin in a well-stopped bottle. *Note.*—Oleoresin of aspidium usually deposits, on standing, a granular-crystalline substance. This should be thoroughly mixed with the liquid portion before use.—U. S.

The processes of the other pharmacopœias are essentially identical with the above, except that maceration instead of percolation is directed by the P. G. It should be remembered that only that portion of the rhizome is to be used which has still a greenish color; the oleoresin will then have a greenish or brownish-green color, while the entire rhizome with the stipes yields a brown preparation, which not unfrequently forms a jelly, probably from the separation of pectin compounds. The official oleoresin separates a granular deposit of filicic acid, which must be well mixed with the liquid portion on dispensing. The yield is about 10 to 15 per cent. (1–1½ oz. av.).

“The oleoresin, well stirred and diluted with glycerin, should not show any starch-granules when examined under the microscope.”—P. G.

Medical Action and Uses.—Since the introduction into practice of this prepa-

ration, whose activity depends upon the filicic acid it contains, the treatment of *tæniæ* has been rendered prompt and certain, at least so far as relates to the armed *tænia* and *T. bothriocephalus*. It appears to act as a poison to the parasites, which are discharged dead. The medicine may occasion nausea, griping, and even vomiting, but usually acts without causing either pain or uneasiness. It is well to prepare the patient by administering a purgative dose of castor oil or of calomel, or a saline cathartic, in order to remove the mucus in which the head of the parasite is imbedded. This should be done about 12 hours before the oleoresin is administered, and the diet should be restricted to milk and light broths. The oleoresin is best prescribed in capsules each containing 6 or 7 grains (Gm. 0.40–0.46). Some advise that an equal quantity of ether should be contained in every one. Of these capsules two should be taken every 15 minutes until 1½ or 2 fluidrachms (Gm. 6–8) of the oleoresin have been used. In the course of 2 or 3 hours purging begins, and after several stools the worm is generally expelled, dead. It has been suggested that the patient should evacuate the bowel in a vessel nearly full of water, so that the parasite need not break and that its parts may be readily distinguished.

A case of fatal poisoning by 1½ ounces of this preparation is recorded (*Med. Times and Gaz.*, Oct. 1882, p. 482). The oleoresin of *Aspidium marginale*, a common fern of this country, has been successfully used for tape-worm in 3-grain doses.

OLEORESINA CAPSICI, U. S.—OLEORESIN OF CAPSICUM.

Oléorésine (Extrait éthérée) de capsique, Fr.; Spanischpfeffer-Oelharz, G.

Preparation.—Capsicum, in No. 60 powder, 100 parts (10 oz. av.); Stronger Ether a sufficient quantity. Put the capsicum into a cylindrical percolator provided with a stopcock and arranged with a cover and receptacle suitable for volatile liquids; press it firmly, and gradually pour stronger ether upon it until 150 parts (15 oz. av. or about 18 fluidounces) of liquid have slowly passed. Recover the greater part of the ether by distillation on a water-bath, and expose the residue in a capsule until the remaining ether has evaporated. Lastly, pour off the liquid portion, transfer the remainder to a strainer, and, when the separated fatty matter has been completely drained, mix all the liquid portions together. Keep the oleoresin in a well-stopped bottle.—*U. S.*

It is a dark brown-red rather thick liquid, separating on standing a granular deposit of fat, which mechanically encloses a portion of the oleoresin, that may be recovered by washing several times with small quantities of ether. Instead of draining the fat, we prefer to decant the clear oleoresin and wash the remainder as stated. The yield is about 4 per cent. The oleoresin has but little odor, but possesses an extremely hot and fiery taste.

Off. Prep.—*Emplastrum capsici, U. S.*

Medical Uses.—This preparation appears to be nearly superfluous as an internal medicine, since all the virtues it can exert in that manner are sufficiently exhibited by capsicum. It is occasionally added to liniments to increase their rubefacient action, but is more beneficially incorporated in plasters, such as soap or lead plaster, for a similar purpose. The *dose* may be stated at 1 minim (Gm. 0.06), well diluted.

OLEORESINA CUBEBAE, U. S., Br.—OLEORESIN OF CUBE.

Extractum cubebæ, P. G.; Extractum cubebæ æthereum.—Oléorésine de cubébe, Fr.; Kubebenextrakt, G.

Preparation.—Cubeb, in No. 60 powder, 100 parts (10 oz. av.); Stronger Ether a sufficient quantity. Put the cubeb into a cylindrical percolator provided with a cover and receptacle suitable for volatile liquids; press it firmly, and gradually pour stronger ether upon it until 150 parts (15 oz. av. or about 18 fluidounces) of liquid have slowly passed. Recover the greater part of the ether by distillation on a water-bath, and expose the residue in a capsule until the remaining ether has evaporated. Transfer the remainder to a close vessel, and let it stand until it ceases to deposit a waxy and crystalline matter. Lastly, pour off the oleoresin. Keep the oleoresin in a well-stopped bottle.—*U. S.* The formula of *Br.* is practically identical with this.

The German Pharmacopeia has a similar preparation, made, however, by extracting the cubebs with a mixture of equal weights of ether and alcohol; it probably contains less volatile oil, a portion of which must volatilize with the last portions of alcohol,

The oleoresin, as prepared by the above formula, is of a brown-green, or sometimes of a grass-green, color, the difference being due to the presence of more or less chlorophyll. On standing it deposits some waxy matter and cubebin, which are removed by decantation. The remaining liquid, amounting to between 18 and 25 per cent. of the cubebs used, consists mainly of fixed and volatile oils, the active resins, and chlorophyll. An alcoholic ether dissolves more brown coloring matter.

Off. Prep.—Trochisci cubebæ, U. S.

Medical Uses.—Investigations for the purpose of discovering upon which of the constituents of cubeb its medicinal value depends have not reached a perfectly definite conclusion, but it may be considered that its most active element is cubebic acid, which, when taken in doses of from 70 to 90 grains (Gm. 4.60–6), produces a lively sensation of heat in the stomach, increases the urine, and renders it hot and irritating. In the dose of 150 grains (Gm. 10) it occasions also eructation, flatulence, a pervading sense of warmth, and some quickening of the pulse. The *dose* of the oleoresin is stated to be from 5 to 30 minims (Gm. 0.30–2), which may be given on sugar or preferably enclosed in gelatin capsules.

OLEORESINA LUPULINI, U. S.—OLEORESIN OF LUPULIN.

Oleoresina lupulina, U. S. 1870; *Extractum lupulini æthereum*.—*Oléorésine de lupuline*, Fr.; *Ätherisches Lupulinextrakt*, G.

Preparation.—Lupulin 100 parts (10 oz. av.): Stronger Ether a sufficient quantity. Put the lupulin into a narrow cylindrical percolator provided with a stopcock and arranged with a cover and receptacle suitable for volatile liquids; press it firmly, and gradually pour stronger ether upon it until 150 parts (15 oz. av. or about 18 fluidounces) of liquid have slowly passed. Recover the greater part of the ether by distillation on a water-bath, and expose the residue in a capsule until the remaining ether has evaporated. Keep the oleoresin in a well-stopped, wide-mouthed bottle.—U. S.

The yield is variable, often about 50 per cent. It is of a dark reddish-brown color and semi-fluid in consistence, and has the odor and taste of the drug.

Medical Uses.—This preparation probably contains all the medicinal virtues of hop. It is, however, seldom used. It may be prescribed in *doses* of from 2 to 10 or more grains (Gm. 0.10–0.60), in pill or capsule.

OLEORESINA PIPERIS, U. S.—OLEORESIN OF PEPPER.

Oléorésine de poivre noir, Fr.; *Ätherisches Pfefferextrakt*, G. •

Preparation.—Pepper, in No. 60 powder, 100 parts (10 oz. av.): Stronger Ether a sufficient quantity. Put the pepper into a cylindrical percolator provided with a stopcock and arranged with a cover and receptacle suitable for volatile liquids; press it firmly, and gradually pour stronger ether upon it until 150 parts (15 oz. av. or about 18 fluidounces) of liquid have slowly passed. Recover the greater part of the ether by distillation on a water-bath, and expose the residue in a capsule until the remaining ether has evaporated and the deposition of piperine, in crystals, has ceased. Lastly, separate the oleoresin from the piperine by expression through a muslin strainer. Keep the oleoresin in a well-stopped bottle.—U. S.

The official process yields about 5 per cent. of a greenish-black oleoresin, consisting of a mixture of volatile and fixed oil holding the pungent resin and some piperine in solution. It is an official substitute for the so-called *oil of black pepper*, which is obtained as a by-product in the manufacture of piperine, and has essentially the same composition, except that the volatile oil is present in small quantity only.

Medical Uses.—The medical uses of this oleoresin are probably few and unimportant, since it contains but a small proportion of piperine, which is of some value as a medicine. Its *dose* is 1 or 2 minims (Gm. 0.05–0.10).

OLEORESINA ZINGIBERIS, U. S.—OLEORESIN OF GINGER.

Extractum zingiberis æthereum.—*Oléorésine (Piperoïde) de gingembre*, Fr.; *Zingiberin*, *Ätherisches Ingwerextrakt*, G.

Preparation.—Ginger, in No. 60 powder, 100 parts (10 oz. av.): Stronger Ether, a sufficient quantity. Put the ginger into a cylindrical percolator provided with a stopcock and arranged with a cover and receptacle suitable for volatile liquids; press it firmly, and

gradually pour stronger ether upon it until 150 parts (15 oz. av. or about 18 fluidounces) of liquid have slowly passed or until the ginger is exhausted. Recover the greater part of the ether by distillation on a water-bath, and expose the residue in a capsule until the remaining ether has evaporated. Keep the oleoresin in a well-stopped bottle.—*U. S.*

Coated ginger yields between 8 and 10 per cent., and the uncoated (Jamaica) ginger between 5 and 7 per cent., of oleoresin, which, as prepared from the latter, is lighter in color, rather more limpid, and perhaps more agreeable in flavor. The appellation *piperoid* originated with Beral. The present process differs somewhat from that formerly official, the use of alcohol for displacing a definite amount of ether poured upon the powdered ginger being abandoned. This was an exception for which there was no good reason, unless the same rule applied to all the official processes for oleoresins.

Medical Uses.—This oleoresin may possibly fulfil some useful purpose for which ginger in substance and its tincture are inadequate. The oleoresin is, in fact, only a concentrated ethereal tincture. The *dose* is 1 minim (Gm. 0.06), largely diluted.

OLEUM ADIPIS, *U. S.*—LARD OIL.

Huile de graisse, Fr.; *Schmalzöl*, *Specköl*, G.

A fixed oil prepared from lard at a low temperature.

Preparation.—Lard is kept for some time near the freezing-point of water enclosed in strong canvas bags, and then subjected to a gradually-increased pressure. About 60 or 62 per cent. of oil is obtained.

Properties.—Lard oil is a thin, transparent, oily liquid, usually of a pale-yellowish color or nearly colorless. Its specific gravity is .9165, but may vary between .910 and .920. If expressed at a sufficiently low temperature the oil becomes opaque near 0° C. (32° F.), and congeals at about -5° C. (23° F.); but the commercial oil usually commences to separate a white granular deposit a little below 10° C. (50° F.) and solidifies at or near -1° C. (30° F.). Good lard oil has a slight fatty odor, is free from rancidity, and has a bland taste.

Composition.—Its consists mainly of olein, with variable quantities of palmitin and stearin.

Off. Prep.—Unguentum hydrargyri nitratis, *U. S.*

OLEUM ÆTHEREUM, *U. S.*—ETHEREAL OIL.

Oleum vini.—Heavy oil of wine, E.; *Huile d'éther*, *Huile de vin pesante*, *Huile volatile éthéré*, Fr.; *Schweres Weinöl*, G.

Formula $(C_2H_5)_2SO_4 \cdot (C_2H_5)_2SO_3 = C_8H_{18}S_2O_7$.

A volatile liquid consisting of equal volumes of heavy oil of wine and of stronger ether.

Preparation.—Alcohol 24 parts (24 oz. av. or 28 fluidounces); Sulphuric acid 54 parts (54 oz. av.); Distilled Water 5 parts (1 oz. av.); Stronger Ether a sufficient quantity. Add the acid slowly to the alcohol, mix them thoroughly, and allow the mixture to stand for 12 hours; then pour the clear liquid into a tubulated retort of such capacity that the mixture shall nearly fill it. Insert a thermometer through the tubulure so that the bulb shall be deeply immersed in the liquid, and, having connected the retort with a well-cooled condenser, distil by means of a sand-bath at a temperature between 150° and 157° C. (302°–314.6° F.) until the liquid ceases to come over or until a black froth begins to rise in the retort. Separate the yellow ethereal liquid from the distillate, and expose it to the air for 24 hours in a shallow capsule. Then transfer the remaining liquid to a wet filter, and when the watery portion has drained off, wash the oil which is left, while on the filter, with the distilled water. When this also has drained off, transfer the oil to a graduated measure, and add to it an equal volume of stronger ether.—*U. S.*

The reaction upon each other of alcohol and sulphuric acid in the production of ether is explained under ÆTHER, page 122. sulphovinic acid, $HC_2H_5SO_4$, being first formed.

When this acid is heated with a further supply of alcohol, ether distils over; if water instead of alcohol be added and then heat applied, alcohol distils over and sulphuric acid is set free; on heating the sulphovinic acid by itself, gas is copiously given off, consisting chiefly of ethylene (*æthene*, *étyl*, *olefiant gas*), C_2H_4 , sulphuric acid being regenerated; $HC_2H_5SO_4$ yields C_2H_4 and H_2SO_4 , while the free sulphuric acid determines further decomposition, the mass becomes charred, and sulphurous and carbonic acids are met with

among the gaseous products. On heating sulphuric acid to about 150°C . (302°F .) and adding slowly sulphovinic acid, heavy oil of wine is produced, besides other gaseous compounds and carbonaceous matter.

Instead of operating with pure sulphovinic acid, alcohol and sulphuric acid may be allowed to react upon each other, whereby the products must necessarily be still more complicated, owing to the presence of uncombined alcohol and sulphuric acid, together with water and sulphovinic acid, which have resulted from the reaction of the two former; in all cases the temperature to which such mixtures are heated exerts an important influence, determining, as it rises, further decomposition. On keeping sulphuric acid at a temperature of 160°C . (320°F .) and passing the vapors of absolute alcohol into it, Lœs obtained ethylene, sulphurous acid, water, and heavy oil of wine, while the retort contained sulphuric, isæthionic, and thiomelanic acids; but on previously diluting the acid with water to the amount of 30 per cent. and using 80 per cent. alcohol, Mitscherlich obtained in the distillate only water and ethylene, with traces of alcohol and ether. The carbonaceous mass mentioned before has been named *thiomelanic acid*; it is a black, rather dense, glossy mass, forming with bases insoluble compounds, and having a complex composition, approaching the empirical formula $\text{C}_{22}\text{H}_{16}\text{SO}_7$. *Isæthionic acid*, $\text{C}_2\text{H}_3\text{HSO}_4$, is syrupy, and isomeric with sulphovinic acid.

The production of heavy oil of wine evidently depends upon the absence of water and the generation of sulphurous acid, the latter being accompanied by the production of thiomelanic acid. An excess of sulphuric acid is required for this purpose, and this is directed in the above formula, the quantity of acid being about four times greater than is theoretically necessary for the production of sulphovinic acid. On mixing the acid and alcohol a turbidity is seen, and subsequently a white precipitation takes place, consisting of sulphate of lead, which was dissolved in the sulphuric acid; this should be removed to avoid the concussions, which would endanger the safety of the retort. When distillation begins, ether and water come over, which are followed by sulphurous acid gas, ethylene, and heavy oil of wine, and the distillate finally consists of an aqueous solution of sulphurous acid and a yellowish ethereal solution of the oil. The gaseous acid should be conducted into the open air or may be utilized for the preparation of sulphites. By exposing the ethereal portion of the distillate to the air, the ether evaporates, leaving the oil contaminated with some acid watery liquid, which is removed by draining upon a wet filter and washing, after which the oil is measured and dissolved in an equal volume of ether. This has been found necessary to avoid the spontaneous decomposition and separation into two liquids which would otherwise take place.

The process now official is essentially that devised by Squibb (1858), with some modifications suggested by C. L. Diehl (1864). The proper management of the heat influences the yield very considerably: to reduce the formation of ether to its smallest quantity, the mixture should be rapidly heated to near the lowest temperature mentioned in the directions (302°F .), and should never be permitted to fall much below it; if it should arise above 160°C . (320°F .), there is great danger of foaming to such an extent that the mixture will run over and the charge be lost. Diehl found it of advantage to let the temperature rise to 157°C . or 158°C . (314.6° or 314.4°F .), then to dampen the fire and allow the distillation to proceed spontaneously until the temperature is reduced to 150°C ., when heat is again cautiously applied as before, and then heating repeated four or five times until the charge is nearly exhausted, which requires from 10 to 12 hours when working with 5 to 7 gallons of the mixture. The attention required for smaller quantities is nearly the same. With good management the yield varies between about 1.6 and 2.3 per cent., and averages about 2 per cent. of the weight of the alcohol employed. (See also a paper in *Amer. Jour. Phar.*, 1865, p. 100.)

Properties.—Pure heavy oil of wine is a yellowish, thickish, oily liquid of a peculiar aromatic odor and pungent, refreshing, bitterish taste, somewhat like that of mint. It is neutral to test-paper, and has the specific gravity 1.129, or, according to Serullas, 1.133, when quite pure. It is very slightly soluble in water, but dissolves readily in alcohol and ether. On being kept for some time crystals of *etherin* are separated, which have the same elementary composition as ethylene, are nearly tasteless, and on warming have an odor similar to that of oil of wine: the crystals have the spec. grav. .98, melt at 110°C . (230°F .), and distil at 260°C . (500°F .) without leaving any residue. In contact with cold water the oil of wine is slowly, with warm water rapidly, decomposed into sulphovinic acid and light oil of wine containing etherin in solution. This light oil of wine, or *etherol*, has likewise the elementary composition of ethylene, but its formula is probably C_8H_{16} ; it is yellowish, of a peculiar odor, specific gravity 0.921,

insoluble in water, soluble in alcohol. It boils at 280° C. (536° F.), is tough like turpentine at -25° C. (-13° F.), and solid at -35° C. (-31° F.).

Diluted with ether, as directed by the Pharmacopœia, oil of wine has the specific gravity 0.910, a pale-yellowish color, and an ethereal odor, besides that peculiar to the pure oil.

Composition.—The analyses of Serullas, Liebig, and others lead to the empirical formula $C_8H_{18}S_2O_7$. Serullas regarded heavy oil of wine as the double sulphate of ethyl and ethylene; Liebig, as ethylsulphate (sulphovinate) of etherol: the latter view appears to be the more correct one if the decomposition with water is taken into consideration. Alkalies also decompose it into sulphovinate of the alkali, liberating etherol. Or it may be related to *sulphuric ether* or *ethyl sulphate*, discovered by Wetherill (1848), which is a yellowish oil of the specific gravity 1.120, has a peppermint-like odor and pungent taste, and the composition of which is expressed by the formula $(C_2H_5)_2SO_4$. *Sulphurous ether* or *ethylsulphite*, $(C_2H_5)_2SO_3$, which was discovered by Ebelmen and Bouquet (1845), has the spec. grav. 1.17 at 0° , boils at 208° C. (406.4° F.), and is decomposed by potassa into potassium sulphite and alcohol.

E. C. Hartwig (1881) examined the oily liquid which may be obtained by distilling the acid residue left in the distillation of ether. This oil has been sold as oil of wine, but is totally different from both the heavy and light oils of wine mentioned above, and consists of hydrocarbons, ethers, and ketones, among them *ethylamylic ether*, $C_2H_5 \cdot C_5H_{11}O$, which boils at 112° C. (233.6° F.); *diisamylene*, $C_{10}H_{20}$, boiling at 157° C.; *ethylamyl ketone*, $C_7H_{13} \cdot C_5H_{11}CO$, boiling near 155° C. (311° F.); and several others having a higher boiling-point.

Off. Prep.—*Spiritus ætheris compositus*, *U. S.*

Medical Uses.—Ethereal oil is not used as a medicine except as an ingredient of the compound spirit of ether.

OLEUM AMYGDALÆ AMARÆ, *U. S.*—OIL OF BITTER ALMOND.

Oleum amygdalarum (amararum) æthericum.—*Essence d'amandes amères*, Fr.; *Bitter-mandelöl*, G.

The volatile oil obtained from the seeds of *Amygdalus communis*, var. *amara*, Linné.

Nat. Ord.—Rosaceæ, Amygdaleæ (see page 188).

Preparation.—Bitter almonds are deprived of most of their fixed oil by pressure between warm plates; the press-cake is powdered, mixed with about six times its weight of water, the mixture digested for a day or two at a temperature of about 50° C. (122° F.), and then distilled.

The oil does not pre-exist in the almonds, but is produced through the decomposition of amygdalin by emulsin, hydrocyanic acid and sugar being at the same time formed; $C_{20}H_{27}NO_{11}$ (amygdalin) and $2H_2O$ yield $C_{12}H_{23}O_{12}$ (glucose), C_7H_6O (oil of bitter almond), and HCN (hydrocyanic acid). This decomposition must first be effected before distillation is resorted to; but while digesting the mixture too high a heat must be avoided, which would coagulate the emulsin and render it ineffective. Distillation by superheated steam is preferable to the use of the naked fire, in order to avoid empyreuma. The water from which the volatile oil has been separated still retains notable quantities of it in solution, which may be recovered by fractional distillation. To avoid the troublesome concussions during distillation, and to bring all the amygdalin under the influence of emulsin, Michael Pettenkofer (1861) recommends the exhaustion of the greater portion of the bitter-almond cake with boiling water, whereby the albuminoids are coagulated and the amygdalin is dissolved from the softened tissue; one-twelfth of the press-cake, unboiled, is then added to the cold mixture, and after sufficient maceration distillation is proceeded with. The yield varies considerably, but is usually over 1 per cent., and occasionally reaches 3 per cent. The importation of the oil into the United States amounted to 1602 pounds in 1877, and to 4093 pounds in 1883.

Properties.—Oil of bitter almond is colorless or yellowish, limpid, has a peculiar aromatic odor, resembling that of hydrocyanic acid, and a bitter and burning taste. Freshly prepared, it has in alcoholic solution a neutral reaction to test-paper, but old oil changes the color of blue litmus to red. It varies in spec. grav. between 1.06 and 1.075, and boils at about 180° C. (356° F.). When freed from hydrocyanic acid and rectified, its spec. grav. is lowered to 1.043 or 1.049, but it retains the aromatic almond odor. It is soluble in 300 parts of water and in all proportions of alcohol and ether. It also dissolves without change of composition in cold nitric or sulphuric acid, but with fuming

or with warm nitric acid it is first converted into crystallizable nitrobenzaldehyd, and finally into benzoic acid, red nitrous vapors being evolved. With concentrated sulphuric acid bitter-almond oil turns deep-red, and on warming black, with evolution of carbonic acid gas. On being agitated with an aqueous solution of potassium bisulphite a crystalline compound is formed.

Composition.—Pure oil of bitter almond was formerly regarded as the hydride of the radical benzoyl (C_7H_5O), but in its chemical relation it is the aldehyd of *benzalcohol*, C_7H_5O , which was discovered by Cannizaro (1853), is a colorless, faintly aromatic oil, and by careful oxidation yields *benzaldehyd* or bitter-almond oil, C_7H_6O , and this, by further oxidation on exposure to the air or by means of oxidizing agents, is converted into benzoic acid, $C_7H_6O_2$. It is this latter compound which crystallizes from old oil of bitter almonds.

Pure benzaldehyd (*artificial oil of bitter almond*) is now largely made in Europe from *toluol*, C_7H_8 , a liquid hydrocarbon contained among the products of the destructive distillation of coal.

The crude oil contains variable quantities of *benzimid*, *benzoin*, and *hydrocyanic acid*, from the latter of which it may be freed by agitation with mercuric oxide, or, preferably, ferrous hydrate (a mixture of lime with solution of ferrous sulphate), and subsequent distillation. Potassa and other alkalies may likewise be employed, but an excess is apt to decompose the oil with the production of benzoic acid and benzalcohol. According to Völkel, hydrocyanic acid is contained in the crude oil in the form of a compound, $C_7H_5O.HCN$, which is a yellowish, nearly inodorous, bitter oil of spec. grav. 1.124, and boiling at $170^\circ C.$ ($338^\circ F.$). *Benzimid* has the composition $2(C_7H_5O.C_7H_6(CN)_2)$, and forms in the pure state colorless, pearly, inodorous crystals, which on being boiled with water and hydrochloric acid are decomposed into oil of bitter almond, formic acid, and ammonia. *Benzoin*, $C_{11}H_{12}O_2$, crystallizes in inodorous and tasteless, colorless prisms which are polymeric with oil of bitter almond, and are converted into the latter by passing their vapor through a red-hot tube.

Adulterations.—The principal adulterations are nitrobenzol, alcohol, and chloroform, the last two being sometimes used together to leave the specific gravity unchanged. By distilling a little of the suspected oil from a test-tube placed in a water-bath kept at a temperature not exceeding $65^\circ C.$ ($149^\circ F.$), the chloroform will distil over, while alcohol will distil at about $80^\circ C.$ ($176^\circ F.$), the distillates showing the behavior of these compounds. On dropping oil of bitter almond containing alcohol into water, the drops, while floating or subsiding in the water, will become milk-white. *Nitrobenzol* (see NITRO-BENZOLUM) has an odor similar to that of bitter-almond oil and a sweet taste, and is nearly insoluble in water. We found it convenient (1857) to test for it by dissolving 15 grains of the oil in 2 drachms of alcohol, adding 15 grains of caustic potassa, heating for a few minutes, evaporating to one-third, and cooling. The pure oil will leave a brownish-yellow liquid, soluble in water, with but slight turbidity; while if nitrobenzol be present the residue will be dark-brown, sometimes crystalline, and not dissolve clear in water, depositing a brown-yellow sediment in proportion to the amount of the adulterant. The test depends upon the conversion of nitrobenzol, $C_6H_5NO_2$, into *azobenzid*, $C_{12}H_{10}N_2O$, which dissolves in alcohol and ether, but is insoluble in water. Wagner (1866) proposed to agitate 5 Ccm. of the suspected oil with 10 Ccm. of solution of sodium bisulphite spec. grav. 1.225, and dilute with water to 50 Ccm. in a graduated tube; pure bitter-almond oil will dissolve, while the nitrobenzol (spec. grav. 1.20) will separate as an oily layer. More delicate tests for this substance depend upon its reduction to *aniline*. According to Hoffmann (1845), the oil is diluted with ether and some alcohol, after which some zinc and hydrochloric acid are added; after the evolution of hydrogen has ceased the ethereal layer is evaporated spontaneously, and the residue mixed with a few drops of solution of chlorinated lime, when a purplish-blue color will be produced. Jacquemin (1876) recommended adding a few drops of the oil to a solution of stannous chloride in caustic soda, and afterward a drop of carbolic acid and some solution of chlorinated soda, when the blue color of erythrophenylate of sodium will appear. Boyveau (1879) noticed an adulteration with a substance of undetermined origin, which gives with an equal volume of sulphuric acid a red mixture, changing to brown, turbid, becoming thick, and in a few days solidifying, while a similar mixture with pure bitter-almond oil darkens in color, but remains liquid and clear.

Pharmaceutical Preparations.—IODINIZED OIL OF BITTER ALMOND was proposed by Dr. Blackwell (1878). It is prepared by leaving in contact for two or three months 1 part of iodine and 2 parts of oil of bitter almond, and dissolves easily in alco-

hol. ether, glycerin, fats, etc. It probably contains *benzol iodide*, C_7H_5O , which was discovered by Liebig and Wöhler (1832), and when pure crystallizes in colorless fusible laminae having a somewhat pungent aromatic odor.

Off. Prep.—Aqua amygdalæ amaræ, U. S.

Medical Action and Uses.—Oil of bitter almond exceeds diluted hydrocyanic acid in its poisonous power, since 100 parts of the oil contain nearly 13 parts of anhydrous hydrocyanic acid, while the diluted acid contains but 2 per cent. of the latter compound. 1 drop of it has been known to kill a cat. In man's grave and even fatal effects have resulted from a dose of 17 drops, but, on the other hand, recovery has taken place after the swallowing of $\frac{1}{4}$ ounce or more when remedial measures were at once applied. Medicinally, it is one of the best forms in which hydrocyanic acid can be administered, owing to its comparatively stable composition. The proper occasions for its use are indicated under HYDROCYANIC ACID. It may be prescribed in doses varying from $\frac{1}{4}$ drop to 1 drop (Gm. 0.015–0.05), and conveniently in mixture of almond.

OLEUM AMYGDALÆ EXPRESSUM, U. S.—ALMOND OIL.

Oleum amygdalæ, Br.; *Ol. amygdalarum*, P. G.; *Ol. amygdalæ dulcis*.—Expressed (sweet) oil of almond, E.; *Huile d'amande (douce)*, Fr.; *Mandelöl, Süßmandelöl*, G.

The fixed oil expressed from the seed of *Amygdalus communis*, var. *amara* or *dulcis*, Linné.

Nat. Ord.—Rosaceæ, Amygdalæ (see page 188).

Preparation.—Almond oil is made both from sweet and bitter almonds. To obtain an unobjectionable oil, the almonds are freed from adhering dust by agitating them upon a sieve and removing discolored pieces, after which they are ground or well bruised in an iron or stone mortar, enclosed in canvas bags, and subjected to considerable pressure between polished steel plates, which should not be heated beyond about 30° C. (86° F.). The oily edges of the press-cake may be powdered and again expressed, when an additional quantity of oil will be obtained. The yield is 40 to 45 per cent. from sweet, and 35 to 38 per cent. from bitter, almonds; a little more when a hydraulic press is used. Expressing the residue at a higher temperature will yield more oil, which, however, is of inferior quality. The expressed turbid oil is set aside in a cool place, and then decanted from the sediment, which may be filtered. Over 30,000 pounds are annually imported into the United States; in 1867 only 10,544 pounds were entered.

Properties.—The oil is nearly colorless or of a pale-straw color, almost inodorous, and has a bland slightly nutty taste. It is a thin oily fluid, and does not congeal until cooled to about –20° C. (–4° F.); its specific gravity is 0.914 to 0.920; exposed to air, it readily turns rancid, acquiring an acid odor and taste, dissolving in all proportions in pure ether, chloroform, benzin, fixed oils, etc., but it is not a drying oil. It dissolves sparingly in alcohol and readily in the usual solvents for fats; alcohol on being agitated with the oil dissolves most of the coloring matter of the latter, together with a small proportion of the oil.

Composition.—It consists mainly of olein, with a minute quantity of palmitin. (See OLEUM OLIVÆ.)

Tests.—Sulphuric acid and chlorinated lime (see OLEA PINGULE) will detect most of the cheaper oils, the behavior with the former reagent having been adopted as the test of purity by the U. S. P. “If 15 parts of the oil be well agitated with a mixture of 3 parts of fuming nitric (nitroso-nitric) acid and 2 parts of water, the mixture should be whitish, not brown or red (absence of cotton-seed, ground-nut, benne, etc. oil), and after several hours should form a solid white mass (absence of drying oils), the aqueous liquid being nearly colorless.”—P. G. The expressed oil of bitter almonds forms a rather soft solid by this treatment.

The oils of *peach*- and *apricot-seeds* are very similar to almond oil. Their presence may, however, be shown, according to Hager (1870), by agitating the oil with an equal bulk of 25 per cent. nitric acid, which mixture may be warmed to 60° C. (140° F.), and still remain white or faintly yellowish if the almond oil be pure, but become deeper yellow in proportion to the amount of the other oils present. The two oils mentioned become at once yellowish, and gradually orange-yellow. Bieber (1877) recommended mixing 5 parts of the oil with 1 part of a cold mixture consisting of equal weights of sulphuric acid, water, and fuming nitric acid. Almond oil gives a yellowish-white mixture; oil of peach-kernels, a reddish one, changing to dark orange; benne oil, yellowish-red, becoming orange-red; an admixture of 5 or 10 per cent. of one of these oils may thus be detected.

When agitated with half its bulk of solution of lead subacetate, almond oil yields a nearly white emulsion-like mixture, while a similar mixture prepared with other oils is mostly more or less yellow. Almond oil, exposed in a test-tube for 20 minutes to a temperature of -5°C . (23°F .), should not produce a white granular deposit (absence of olive oil, lard oil, etc.).

Off. Prep.—Oleum phosphoratum, *U. S. Br.*; Unguentum aquæ rosæ, *U. S.*; Unguent. cetacei, Unguent. hydrarg. oxidi rubri, Unguent. plumbi subacetat. comp., Unguent. simplex, *Br.*

Medical Action and Uses.—The expressed oil of almond is a singularly bland and agreeable oil and very useful as a demulcent. It was formerly used to allay cough and all irritations of the respiratory passages. It may be prescribed in doses of 1 or several fluidrachms (Gm. 4–16) in an emulsion made with mucilage or yolk of egg and white sugar.

OLEUM ANETHI, *Br.*—OIL OF DILL.

Essence d'aneth, Fr.; Dillöl, G.

Preparation.—The volatile oil is obtained from the fruit of *Anethum graveolens*, *Linne* (nat. ord. Umbelliferae), by distillation with water. The yield is about 3 to 5 per cent.

Properties.—Oil of dill has a pale-yellow color, gradually changing to reddish-brown, the peculiar aromatic odor of the fruit, and a sweetish and warm afterward pungent taste. Its specific gravity varies between .85 and .89, and its rotating power is about 206° to the right. It dissolves iodine with the evolution of some vapors, and is colored red-brown by sulphuric acid.

Composition.—The oil contains a hydrocarbon, *anethene*, $\text{C}_{10}\text{H}_{16}$, which has an odor resembling that of lemon, and an oxygenated portion which, according to Gladstone (1872), is isomeric with the *carvol* of oil of caraway. This carvol is obtained by treating the oil with alcoholic solution of ammonium sulphide and decomposing the crystalline compound with an alkali. Both fractions are dextrogyre. According to Nietzki (1874), the oxygenated oil is identical with carvol, and amounts to about 30 per cent., while the terpene consists of two compounds—one boiling between 155° and 160°C . (311° and 320°F .), and having the odor of turpentine; it amounts to about 10 per cent. of the oil; the remaining fraction of 60 per cent. boils between 170° and 175°C . (338° and 347°F .), has a mace-like odor, and acquires the characteristic dill odor on the addition of a little carvol.

Medical Action and Uses.—Oil of dill is very seldom used in this country; like anise oil, etc., it may be employed to relieve flatulent colic and externally as an anodyne. *Dose*, from 2 to 5 drops (Gm. 0.10–0.30), in hot water and sugar.

OLEUM ANIMALE ÆTHEREUM.—ANIMAL OIL.

Oleum animale Dippelii.—Dippel's animal oil, *E.*; Huile animale de Dippel, *Fr.*; Ätherisches Thieröl, *G.*

Preparation.—On the dry distillation of bones and other animal substances a fetid, brown, thick, oily liquid is obtained, known as *bone oil*, *crude*, or *fetid animal oil*. This is purified for medicinal use by distilling it in a retort or flask, which is heated by a sand-bath, as long as a thin oil passes over. This is then mixed with four times its weight of water, and rectified in a metallic still as long as the distillate is colorless or but slightly yellow. The oily liquid is separated from the water, and at once put into small vials, well corked and preserved in a dark place. Though previously known and medicinally employed, it was first prepared from dried blood by J. C. Dippel in 1711.

Properties.—Rectified animal oil is a colorless or yellowish, thin, oily liquid which has the average spec. grav. 0.80. It has a very penetrating empyreumatic and ethereal but not a fetid odor, and a pungent, acrid, afterward cooling and bitter taste. It has a slight alkaline reaction to test-paper, dissolves in about 80 parts of water, and is readily soluble in alcohol, ether, and fixed and volatile oils. Exposed to light and air, it rapidly darkens in color and acquires a thicker consistence.

Constituents.—This is a very complex mixture, containing a large number of volatile bases like *pyrrol*, $\text{C}_4\text{H}_5\text{N}$, *pyridine*, $\text{C}_5\text{H}_5\text{N}$, *picoline*, $\text{C}_5\text{H}_7\text{O}$, *lutidine*, $\text{C}_7\text{H}_9\text{N}$, *collidine*, $\text{C}_8\text{H}_{11}\text{N}$; also methylamine, propylamine, butylamine, and others. It contains also a neutral liquid which boils at 65.5°C . (150°F .), and different hydrocarbons.

Pharmaceutical Preparation.—Ammonii carb. pyro-oleosa (p. 178).

Physiological Action and Medical Uses.—Given to dogs, it produces paralysis of the hinder legs and general convulsions. A fluidrachm (Gm. 4) of this oil destroyed a medium-sized dog in 15 minutes. Given to man in medicinal doses, it excites a sense of warmth in the abdomen, renders the pulse more frequent and stronger, and increases the sweat and urine. A tablespoonful of it (Gm. 16) is said to have killed a man almost instantaneously, and 1½ ounces (Gm. 48), taken by a woman with suicidal intent, caused violent vomiting and intense pain. After death the mouth and throat were dry and shrivelled and the stomach inflamed and ecchymosed (Werber, *Archiv d. Heilkunde*, xi. 544). Formerly, the oil was used in the *typhoid state* of febrile affections, in *hysteria*, *chorea*, *epilepsy*, *paralysis*, chronic *rheumatism*, and *sciatica*, and to expel *tape-worms*. Internally, it was prescribed in doses of from 5 to 10 drops, and from that to 30 or 40 drops (Gm. 0.30–2.60), mixed with powdered sugar or in sulphuric ether or Hoffmann's anodyne. Externally, it was applied by friction, pure or in liniments.

Formerly, a preparation known as Chabert's oil, and which was procured from a mixture of impure empyreumatic oil with oil of turpentine by distillation, was in high repute as a cure for *tape-worm*. Its offensive taste and smell and harsh action caused it to be laid aside when the various tæniacide medicines now in use began to be employed.

OLEUM ANISI, U. S., Br.—OIL OF ANISE.

Essence d'anis, Fr.; *Anisöl*, G.

The volatile oil distilled from the fruit of *Pimpinella Anisum*, *Linneé* (nat. ord. Umbelliferae, see p. 207), and the oil distilled from the fruit of *Illicium anisatum*, *Linneé* (nat. ord. Magnoliaceae, see p. 811). The latter is properly called *Oleum anisi stellati* (*Ol. badiani*, *Ol. illicii anisati*).—Oil of illicium or of star-anise, *E.*; Huile volatile de badiane, *Fr.*; Sternanisöl, *G.*

Preparation.—The oil is obtained by distillation of the fruit with water. The yield from anise is 1½ to 2½ per cent.; from star-anise, 2½ to 4 per cent.

Properties.—Both volatile oils are pale-yellow, becoming darker by age, and have a sweet aromatic taste and an agreeable aromatic odor, differing somewhat in the two oils. The spec. grav. is .97 to .99, rising in old oils sometimes to 1.028 (Zeller). At a low temperature the oils solidify into a crystallizing mass, the freezing-point of the true anise oil being usually near 10° C. (50° F.), and of star-anise oil near 2° C. (35.6° F.). It varies, however, very considerably, not only in oils as obtained from different material, but because it changes on keeping and becomes lower; the requirement of the U. S. Pharmacopœia, that oil of anise "at 10° to 15° C. (50°–59° F.) solidifies to a crystalline mass which does not resume its fluidity until the temperature rises to about 17° C. (62.6° F.," is too strict, and would exclude pure oils. The German Pharmacopœia formulates this property as follows: "The oil congeals in the cold to a white crystalline mass, which melts partly at 15° C. (59° F.), and when completely fused forms a colorless, strongly refractive, very aromatic liquid." The volatile oil distilled from anise-chaff (pedicels, unripe fruit, etc.) is said to contain more stearopten and to congeal at a higher temperature than the oil of the ripe fruit (Martius). The reactions of the oils of anise and of illicium are so similar that they do not afford any reliable means for distinguishing them. Both oils are entirely neutral to test-paper, have a very slight right or left rotating power, are freely soluble in alcohol, and with strong alcohol form clear solutions in all proportions. The importation of anise oil into the United States increased from 3900 pounds in 1867 to 30,659 pounds in 1883, and was only 4000 pounds in 1878.

Composition.—Oil of anise contains a small quantity of a hydrocarbon having the composition $C_{10}H_{16}$, but consists mainly of *anethol*, $C_{10}H_{12}O$, sp. grav. .98; this exists in two modifications—one liquid, the other solid, at the ordinary temperature and fusing at about 20° C. (68° F.), and both boiling between 220° and 225° C. (428° and 437° F.); they are present also in oil of fennel, and a liquid modification in the oil of *Artemisia Dracunculus*, *Linneé*, or *tarragon*, has the spec. grav. .945 and boils at 206° C. (402.8° F.). *Anethol* has a fainter but more agreeable odor than oil of anise. It is not altered on being boiled with potassa solution; chromic acid converts it into colorless, inodorous, and nearly tasteless crystals of *anisic acid*, $C_8H_6O_3$; nitric acid yields the same compound, or *anisole*, *anisylie*, and *oxalic acids*, according to its concentration and duration of action. Sulphuric acid colors it red, and water separates afterward inodorous *anisoin*; this is isomeric with *anethol*, like *metanethol* and *metanethol camphor*, which are produced under certain conditions. Landolph (1875) found Russian oil of anise to contain 90 per cent.

of a mixture of anisic aldehyd and anise camphor, to which he gives the formula $C_{10}H_{16}O$.

Adulterations.—(Oil of anise has been met with adulterated with alcohol, camphor, wax, and spermaceti, the last three for the purpose of raising its congealing-point. Anise oil adulterated with alcohol becomes milk-white on being dropped into water. Camphor is detected in the pressed crystalline mass by its odor, the other two by their insolubility in 80 per cent. alcohol. Leonhardi (1878) reports the oil to be sometimes largely adulterated with the stearopten of Russian fennel oil, which is detected by the fennel odor developed on heating.

Tests.—The solution in alcohol should not become dark-colored on the addition of a little ferric chloride (phenol, etc.). 1 drop of anise oil, triturated with sugar and afterward agitated with 500 Gm. of water, should impart to the latter the pure flavor of anise (absence of other volatile oils).—*P. G.*

Pharmaceutical Preparations.—LIQUOR AMMONII ANISATUS, *P. G.* Dissolve 1 part of oil of anise in 24 parts of alcohol, and add 5 parts of ammonia-water. The liquid is yellowish and clear.

Off. Prep.—Essentia anisi, *Br.*; Spiritus anisi, *U. S.*; Tinct. opii ammoniata, *Br.*; Tinct. opii camphorata (camphoræ comp.), *U. S. Br.*; Trochisci glycyrrhizæ et opii, *U. S.*

Medical Action and Uses.—Like other aromatic essential oils, when given to animals in large doses it occasions lethargy and insensibility. In medicinal doses it acts as a local and general stimulant, and is used to expel *flatus*, allay *colic*, and prevent the griping of drastic purgatives. It has also been employed in the treatment of *chronic bronchitis*, associated with carbonate or muriate of ammonium. It may be prescribed in doses of from 2 to 6 drops (Gm. 0.1–0.40), on sugar or in emulsion.

OLEUM ANTHEMIDIS, *Br.*—OIL OF CHAMOMILE.

Oleum chamomille romanæ.—Essence de camomille romaine, *Fr.*; Römischkamillenöl, *G.*

Preparation.—The volatile oil is obtained from the flowers of *Anthemis nobilis*, *Linneé* (nat. ord. Compositæ), by distillation with water. The yield is variable, between about $\frac{1}{8}$ and $\frac{1}{2}$ per cent.

Properties.—Fresh flowers seem to yield a blue-colored oil, while that obtained from dried flowers has a green or yellow color, or if blue changes rapidly to green and yellow. It has the odor of the flowers and a warm, aromatic taste: it imparts a red color to litmus-paper, and begins to boil at about 160° C. (320° F.), the boiling-point rising gradually to above 200° C. (392° F.). It is sometimes distilled from the entire plant, and has then a greenish color, which on exposure changes to yellow. Its specific gravity is .90.

Composition.—The oil does not combine with sodium bisulphite. Potassa decomposes it, and B. Jaffé (1865) separated in this way 58 per cent. of impure and 30 per cent. of pure angelic acid. Demarçay (1875) arrived at the conclusion that it is a mixture of several compound ethers, among which the butylic and amylie angelates and valerianates preponderate. Koebig (1873) did not find valerianic acid, but besides angelate isolated isobutylate and tiglate of anthemol and of a new hexyl ether; these ethers appear to be present in the fresh oil. Demarçay had noticed that under the influence of heat angelic acid is converted into the isomeric tiglic acid.

Off. Prep.—Extractum anthemidis, *Br.*

Medical Action and Uses.—Oil of chamomile is stimulant and anti-spasmodic, and is used to allay vomiting and relieve flatulent *colic* and to modify the irritant action of cathartics in pill or mixture. It is often added to liniments used for sprains, rheumatic pains, etc. *Dose*, from 1 to 5 drops (Gm. 0.05–0.30).

OLEUM AURANTII CORTICIS, *U. S.*—OIL OF ORANGE-PEEL.

Oleum aurantiorum.—Essence d'orange, *Fr.*; Pomeranzenschalenöl, *G.*

A volatile oil extracted by mechanical means from fresh orange-peel.

Nat. Ord.—Aurantiaceæ.

Preparation.—The volatile oils of both the bitter and sweet orange-peel are articles of commerce, and both are prepared in the southern part of Europe by superficially rupturing the ripe fruit, so as to puncture only the oil-glands imbedded under the yellow rind: or the fresh peel is forcibly twisted, which operation causes the glands to discharge the oil, this being collected first upon a sponge, and by wringing the same when saturated

in a suitable bowl. A third method of preparing oil of orange-peel consists in superficially grating the fruit, so as to remove only a thin layer of the rind containing the oil-glands; the grated mass is then deprived of the greater part of the volatile oil by pressure, and the residue is sometimes distilled with water, whereby it yields a less fragrant volatile oil. The importation of oil of orange-peel amounted to 9133 pounds in 1882.

Properties.—The volatile oils of the two orange-peels are distinguished as—

OLEUM AURANTII DULCIS.—Oil of sweet orange-peel, *E.*; Essence d'orange douce, Essence de Portugal, *Fr.*; Äpfelsinenöl, Portugalöl, *G.*

OLEUM AURANTII AMARI.—Oil of bitter orange-peel, *E.*; Essence de Bigarade, *Fr.*; Pomeranzenöl, *G.*

The first one is usually employed in making elixir of orange, but, though it differs from the latter somewhat in flavor and in being more readily altered by exposure to air, the two oils are alike in chemical composition and in all their essential properties. Oil of orange is of a pale or greenish-yellow color, limpid, varies in its specific gravity between 0.835 and 0.885, boils near 180° C. (356° F.), and rotates polarized light considerably to the right. It has a neutral reaction to test-paper, an agreeable orange odor, and an aromatic slightly bitter taste. It dissolves freely in absolute alcohol, and requires about 2 parts of alcohol and about 8 or 10 parts of alcohol spec. grav. .850 for solution; oil of sweet orange-peel dissolves more readily than the bitter variety. Powdered iodine acts energetically upon the fresh oil, producing orange-colored vapors, but with old oil merely a radiating wavy motion without colored vapors. Sulphuric acid causes a deep-red or red-brown color. Nitric acid colors greenish-yellow, and on warming leaves a brown-yellow resin. Exposed to the air, oil of orange gradually becomes thicker and acquires a terebinthinate odor. This change is prevented, or at least considerably retarded, by adding to the oil 5 per cent. of strong alcohol, and decanting or filtering, if necessary, from the precipitate; this is very properly recommended by the Pharmacopœia for preserving the oil.

Composition.—Oil of orange consists mainly of the hydrocarbon *hesperidene*, $C_{10}H_{16}$, and contains a small portion of an oxygenated body, $C_{10}H_{16}O$, boiling near 220° C. (428° F.). Hesperidene yields with hydrochloric acid gas a crystallizable compound having the composition $C_{10}H_{16} \cdot 2HCl$. C. R. A. Wright (1874) obtained also a liquid compound with hydriodic acid, and by oxidation with nitric acid a slowly-crystallizing hexabasic acid, *hesperisic acid*, $C_{20}H_{26}O_{17} \cdot 2H_2O$, was produced. By combining hesperidene with bromine and distilling the compound, *cymene*, $C_{10}H_{14}$, passes over, identical with that contained in cumin oil and with that obtainable from camphor. Wright found also small proportions of a substance, $C_{40}H_{64}O_3$, boiling above 240° C. (464° F.), and of a non-volatile resin, $C_{20}H_{30}O_3$.

Off. Prep.—Elixir aurantii, Spiritus aurantii, Spiritus myrciæ, *U. S.*

Medical Action and Uses.—The essential oil of orange-peel is irritant and narcotic. Persons employed in manufacturing it suffer greatly from erythematous, papular, and vesicular eruptions of the skin, especially of the hands and face, and also from nausea, vomiting, and other dyspeptic symptoms, headache, neuralgia, and a sort of intoxication denoted by confusion of the mind and senses, and impaired muscular power. Oil of orange-peel is used almost exclusively as a flavoring or perfuming ingredient of medicinal compounds.

OLEUM AURANTII FLORUM, *U. S.*, *P. G.*—OIL OF ORANGE-FLOWERS.

Oleum florum naphæ, Oleum neroli, s. naphæ.—Oil of neroli, *E.*; Essence de fleur d'oranger, Néroli, *Fr.*; Pomeranzenblütenöl, Néroliöl, *G.*

A volatile oil distilled from the fresh flowers of *Citrus vulgaris*, *Risso*.

Nat. Ord.—Aurantiaceæ.

Preparation.—This volatile oil is obtained in the preparation of orange-flower water, upon the surface of which it separates in small proportion. It is manufactured chiefly in the southern part of France from the flowers of the bitter orange, which yield about 0.6 per cent. of oil. The flowers of the sweet orange and of allied plants are far less aromatic and have a more or less different odor. Over 400 pounds of oil of neroli were imported into United States in 1882.

Properties.—According to Flückiger and Hanbury, pure oil of neroli is of brownish hue, a bitterish aromatic taste, neutral to test-paper, and of the density of 0.889 at 11° C. (51.8° F.). It shows a bright violet fluorescence when mixed with alcohol, or more

distinctly by pouring a little alcohol on the surface of the oil and causing the liquid to gently undulate. The oil assumes an intense permanent crimson hue on being shaken with a concentrated solution of bisulphite of sodium. Although very fragrant, the odor of the volatile oil differs somewhat from that of orange-flowers and of distilled orange-flower water. The oil dissolves, according to Zeller, in from 1 to 3 parts of alcohol spec. grav. .850, the solution becoming opalescent or turbid with more alcohol. Carbon disulphide likewise yields a turbid solution (Flückiger). Iodine acts energetically upon neroli oil, colored vapors being given off; sulphuric acid colors it dark orange-red or red-brown; nitric acid changes the color to yellow and rust-brown. The oil deviates polarized light somewhat to the right. The commercial oil is usually yellowish or reddish-yellow, and is frequently adulterated with oil of bergamot and orange-leaves. Old resinified oil is less fragrant, but may, in a measure, be restored by rectification with water.

Composition.—Oil of neroli is a hydrocarbon, $C_{10}H_{16}$, containing a small quantity of inodorous crystallizable camphor. The former distils between 185° and 195° C. (365° and 383° F.), displays the violet fluorescence in a marked manner, and retains the odor of the original oil (Flückiger). Neroli camphor was observed by Boullay (1828), and, according to Plisson (1829), may be obtained from the oil by treatment with alcohol of spec. grav. .850, in which it is nearly insoluble. It crystallizes from ether or hot alcohol in pearly needles or prisms, melts at 55° C. (131° F.), and when pure is inodorous and tasteless.

Off. Prep.—*Spiritus odoratus, U. S.*

Medical Action and Uses.—Oil of orange-flowers belongs rather to the perfumer's than to the pharmacist's art, but it may be employed to mask the smell of mixtures, ointments, etc.

OLEUM BERGAMII, U. S.—OIL OF BERGAMOT.

Oleum bergamottæ.—*Essence de bergamotte, Fr.; Bergamottöl, G.*

The volatile oil obtained by mechanical means from the fresh rind of the fruit of *Citrus Bergamia*, var. *vulgaris*, *Risso et Poiteau*, s. *C. Aurantium*, var. *Bergamia*, *Wight et Arnott*, Bentley and Trimen, *Med. Plants*, 52.

Origin.—The fruit is of a lemon-yellow color, and grows upon a small tree in Southern Italy, evidently a variety produced by cultivation; it is by some botanists regarded as closely related to *Citrus Limetta*, *Risso*, or with this plant as a variety of *C. Limonium*, *Risso*, while others regard it as a hybrid of *C. medica* and *C. Aurantium*, *Risso*. The juice of the fruit has a bitter and acid taste.

Preparation.—The oil-vessels contained in the rind of the fruit are ruptured by means of a machine wherein the fruit is subjected to a rotatory motion; the oil thus obtained deposits on standing a waxy matter, from which it is decanted. The amount imported into the United States was 40,460 pounds in 1858, and 51,782 pounds in 1882.

Properties.—Oil of bergamot has a green or greenish, sometimes a yellowish, color, and after rectification is colorless. Its specific gravity varies between .86 and .89, and its boiling-point between 180° and 195° C. (356° and 383° F.). It has a bitterish aromatic taste and an agreeable odor, less pleasant after rectification. It has a neutral or slightly acid reaction to test-paper. It dissolves 25 per cent. of carbon disulphide and 8 per cent. of alcohol .966, and is soluble in half its weight of alcohol sp. gr. .85, and in all proportions in strong alcohol and in glacial acetic acid; the alcoholic solution becomes dingy-brown with ferric chloride. It deviates polarized light to the right from 7° (*Pharmacographia*) to 40° (Gladstone), and reacts briskly with iodine, giving off purplish and yellow vapors.

Composition.—The amount of oxygen has been found to vary between 2.6 and 16.14 per cent. in different portions of the distillate. The oil appears to be a mixture of hydrocarbons of the formula $C_{10}H_{16}$ with various hydrates. Distilled with phosphoric anhydride, a volatile oil of the odor of turpentine is obtained. The waxy matter mentioned above crystallizes from alcohol in silky, colorless, inodorous, and tasteless needles; this *bergamot camphor* or *bergaptene* has the composition $C_{15}H_{24}O_3$.

Adulterations.—Oil of bergamot is often adulterated with oil of orange, and occasionally with oil of turpentine, and requires then a larger amount of alcohol for solution. The volatile oils obtained by distillation with water of the leaves and of the nearly exhausted rind, when mixed with oil of bergamot, render it less fragrant.

Off. Prep.—*Spiritus odoratus, U. S.*

Medical Action and Uses.—It is a stimulant like other volatile oils, but is seldom employed except for the purpose of scenting ointments and toilet tinctures.

OLEUM BUBULUM.—NEAT'S-FOOT OIL.

Oleum pedum tauri, Arungia pedum tauri.—Huile (Graisse) des pieds du gros bétail, Fr.; Klauenöl, Ochsenklauenfett, G.

Preparation.—It is made by boiling neat's feet, deprived of their hoofs, with water, skimming off the oil which rises to the surface, and keeping it for some time on warm water. After the impurities have settled it is ready for use.

Properties.—Neat's-foot oil is a pale-yellow and (when of good quality) nearly odorless and bland, liquid oil, which has the specific gravity .915 at 15° C. (59° F.), is but slightly thickened on exposure, does not readily turn rancid, and requires to be cooled to below the freezing-point of water before it congeals to a soft white mass. On saponification it yields glycerin and oleic acid with a little stearic acid. Neat's-foot oil is turned brown by sulphuric acid or a mixture of sulphuric and nitric acids; nitric acid colors it yellow; and it gradually congeals when in contact with nitroso-nitric acid.

Medical Action and Uses.—Neat's-foot oil is much used in softening leather and rendering it pliable. Perhaps this operation may have suggested its administration in medicine as a substitute for cod-liver oil. If it had been efficient, of which there is no proof, its singularly repulsive smell and taste as it is usually met with, and its tendency to cause diarrhœa, would speedily have condemned it.

OLEUM CAJUPUTI, U. S., Br.—OIL OF CAJUPUT.

Oleum cajuputi, P. G.—Oil of cajuput, E.; Essence de cajuput, Fr.; Cajuputöl, G.

The volatile oil obtained from the leaves of *Melaleuca Cajuputi*, *Roxburgh* (s. *M. minor*, *Smith*). *Trans. Lond. Med. Bot. Soc.*; *Steph. and Church, Med. Bot.*, plate 84; *Bentley and Trimen, Med. Plants*, 108.

Nat. Ord.—Myrtaceæ.

Origin.—The species mentioned is a small tree, which has lanceolate entire leaves and terminal spikes of small white flowers with exserted stamens. It is indigenous to the East Indian Islands. Bentham regards it as a mere variety of *M. Leucadendron*, *Jinné*, which extends into Farther India, the Philippines, and a considerable portion of Australia, and often attains a moderately large size, sometimes growing to the height of 90 feet (27 M.). The oil is prepared in Celebes, Bouro, and other islands of the Molucca Sea by distilling the leaves with water. 1146 pounds of cajuput oil entered the United States in 1867, and 7019 pounds in 1881.

Properties.—Oil of cajuput is limpid, of a green or bluish-green color, a penetrating odor, suggesting that of camphor, rosemary, and mint, and a bitterish, warm, camphoraceous, afterward cooling taste. The specific gravity varies between .914 and .930; its boiling-point is near 173° C. (343.4° F.). It does not congeal at -25° C. (-13° F.), is freely soluble in alcohol, and does not affect litmus-paper. It dissolves iodine quietly or with the evolution of few reddish vapors; ammonia turns it yellowish, and sulphuric acid colors it brown, reddish, and finally purplish-brown. On heating 5 parts of cajuput oil to 50° C. (122° F.), and then adding 1 part of powdered iodine, the solution on cooling congeals to a magma of black crystals, which by recrystallization from alcohol or ether may be obtained as yellowish-green prisms having a metallic lustre, and which liquefy on keeping (*Schmidl*). By rectification the oil becomes colorless.

Composition.—*Blanchet* determined its composition to be $C_{10}H_{16}H_2O$. *Schmidl* (1860) obtained, between 175° and 178° C. (347° and 352.4° F.), two-thirds of the oil as a colorless distillate which has the composition stated, and is the hydrate of a hydrocarbon named *cajuputene*, the latter obtainable by repeated distillation over phosphoric anhydride. *Cajuputene*, $C_{10}H_{16}$, boils between 160° and 165° C. (320° and 329° F.), has an agreeable odor of hyacinth, and is slightly soluble in alcohol. Two other hydrocarbons of the same composition and sparing solubility in alcohol are obtained at the same time, of which *isocajuputene* boils at 176° C. (348.8° F.) and has a less agreeable odor, while *paracajuputene* is thick, yellow, and shows a blue fluorescence. *Gladstone* (1872) found the hydrate of cajuputene, or *cajuputol*, also in the volatile oils of *Melaleuca ericifolia* and *linarifolia*, *Smith*, and of *Eucalyptus oleosa*, *F. Mueller*; it is dextrogyre, its rotating power varying between 10° and 30°.

The green color of the oil is sometimes, at least, in part due to copper, the presence of

which may be proven by agitating the oil with dilute hydrochloric acid when its green color disappears, and testing the watery liquid with ferrocyanide of potassium, when a red-brown color or precipitate will occur. However, cajuput oils have been observed which were entirely free from copper, the green being due to chlorophyll.

Adulterations.—The admixture of oil of turpentine is indicated by decreased solubility in alcohol and the more violent reaction with iodine. Imitations made by mixing various volatile oils are detected by the same means and by their different odor; such mixtures remain liquid when treated with one-fifth of iodine, as described above. The oils examined by Gladstone cannot, it seems, be distinguished from the official.

Off. Prep.—Linimentum crotonis, Spiritus cajuputi, Br.

Medical Action and Uses.—This oil has long been prized in the East as a stimulant and diaphoretic medicine, and employed in dropsy, flatulent colic, chronic rheumatism, paralysis, hysteria, etc. It may be used internally as a remedy for *flatulent colic*, particularly when it is produced by cold or by the retrocession of gout or rheumatism, in *dysmenorrhœa* occasioned by temporary uterine congestion, in *cholera morbus*, and in epidemic *cholera*. In the last-named disease it has been largely employed by Oriental physicians. It is of marked utility in cases of *nervous vomiting*, *nervous dysphagia*, *dyspnœa*, and *hicough*. It has also been used as a *vermifuge*. As a local stimulant and rubefacient it is useful, when diluted with olive oil or added to camphorated liniments, in cases of *functional paralysis* and *muscular rheumatism*. With olive oil or glycerin it is introduced on cotton into the auditory canal for the relief of *otalgia* and of *deafness*. It is one of the best remedies for *toothache* depending upon caries when a drop of it upon cotton is introduced into the hollow tooth, and a few drops of it rubbed upon the painful part relieve *nervous headache* and *local neuralgia*. It is a useful stimulant in chronic *scaly affections of the skin* and in *acne rosacea*. It may be given internally in doses of from 2 to 10 drops (Gm. 0.10–0.60) on sugar, with Hoffmann's anodyne, or with tinctures, or infusions of anti-spasmodic medicines. As a vermifuge it may be mixed with honey in the proportion of 1 part to 30 or more, and dessert-spoonful doses of the mixture may be given every hour or two. It may also be administered by enema.

Melaleuca flaviflora yields an oil which is closely analogous to cajuput oil, and is used for similar purposes by the people of New Caledonia—viz. externally for the relief of neuralgia, muscular rheumatism, and gout, and internally as a vermifuge, especially for rectal ascarides, in enema (*Bull. de thérap.*, xcvii. 402). *M. paraguayensis* is said to be a sudorific. An extract prepared from it has been employed in the treatment of rheumatism, gout, syphilis, yellow fever, and cholera (*Med. Record*, xvi. 132).

OLEUM CARI, U. S.—OIL OF CARAWAY.

Oleum carui, Br.; *Oleum carvi*, P. G.—*Essence de carvi*, Fr.; *Kümmelöl*, G.

The volatile oil distilled from the fruit of *Carum Carui*, Linné.

Nat. Ord.—Umbelliferae.

Preparation.—The bruised fruit is distilled with superheated steam; the yield is variable, but averages about 4 per cent., and may be as high as 7 per cent. The fruit which is grown in northern countries is generally richer in oil than that from more southern localities. The first portion of the distillate contains mainly carvene, the odorous carvol coming over last. 3600 pounds passed into the United States in 1867, and 9143 pounds in 1882.

Properties.—Oil of caraway is limpid, colorless, or pale-yellow, becoming brown and viscid on exposure. Its specific gravity is usually between .90 and .92, but in old oil may rise to .97. When fresh it has no action on litmus; its odor is agreeable, its taste aromatic. It dissolves readily in alcohol, turns polarized light to the right, and commences to boil at 175° C. (347° F.). The German Pharmacopœia recognizes only oil of caraway which has been deprived of much of the carvene; such oil should have a specific gravity of not less than .910, and should boil briskly at 224° C. (435.2° F.); its solution in a equal weight of alcohol should acquire a reddish or pale-violet color on the addition of a drop of test solution of ferric chloride; and a mixture of 10 parts of the oil, 8 parts of alcohol, and 1 part of ammonia-water, on being saturated with hydrosulphuric acid gas, should congeal to a white crystalline mass.

An inferior oil of caraway is made from the refuse or "chaff" of the fruit; it is less agreeable in odor, and not unfrequently mixed with oil of turpentine.

Composition.—By repeated fractional distillation Völkel (1840) separated *carvene*, C₁₀H₁₆, which has little odor and taste, boils at 173° C. (343.4° F.), and has a strong dex-

trogyrate rotation. The higher boiling fraction contains *carvol*, $C_{10}H_{14}O$, which is liquid, has an agreeable caraway odor, boils at $227^{\circ} C.$ ($440.6^{\circ} F.$) (Gladstone), or at $250^{\circ} C.$ ($482^{\circ} F.$) (Varrentrapp), and has a levogyrate rotation. In contact with alcoholic solution of ammonium sulphide carvol yields white silky needles of $(C_{10}H_{14}O)_2 \cdot H_2S$, from which it is again separated by potassa. Carvol (see also OL. ANETHI) is isomeric with menthol of spearmint, myristicol of nutmeg, thymol, cuminic alcohol, and *carvacrol*; the latter is a rather viscid, colorless, or yellowish oil resembling creasote in odor and taste, and may be obtained by distilling a mixture of oil of caraway and potassa until carvene has been expelled, decomposing the residue by sulphuric acid, and rectifying the oil.

Off. Prep.—Confect. scammonii, Pilula aloes Barbada., Br.; Spirit. juniperi comp., U. S.

Medical Action and Uses.—The properties of this oil are nearly identical with those of oil of anise. Given to animals in large doses, it causes death by asthenia. It may be used in the treatment of *flatulent colic* and whenever a gastric stimulant or a carminative is required. Locally, it acts, like other essential oils, as an *anesthetic*. It may be administered in sweetened water, ether, or Hoffmann's anodyne, in the dose of from 1 to 10 drops (Gm. 0.05–0.60).

OLEUM CARYOPHYLLI, U. S., Br.—OIL OF CLOVES.

Oleum caryophyllorum, P. G.—*Es-ence de girofle*, Fr.; *Nelkenöl*, G.

The volatile oil distilled from the flower-buds of *Eugenia caryophyllata*, Thunberg.

Nat. Ord.—Myrtaceæ.

Preparation.—The volatile oil is obtained from cloves by distilling them with water. For this purpose the cloves require to be bruised; cohobation should be repeatedly resorted to, and salt may be added (see OLEA DESTILLATA) in order to raise the boiling-point. If the cloves have been properly bruised, the three or four times repeated distillation of the water from the same cloves is usually sufficient; but if the powder be very coarse the distillation will have to be repeated more frequently. At present the distillation is usually effected with superheated steam. At first, the oil coming over is chiefly the light portion which floats on the water; afterward the heavy portion distills, and the two portions united constitute the commercial article. The yield is 15 to 20 per cent. Clove-stalks are said to be sometimes used in Europe in the distillation of this oil. In the United States cloves from South America are employed for distilling the oil, and the entire want is now supplied in this country. In 1867 the amount imported was 956 pounds, which decreased in 1877 and 1878 to 2 pounds, and was 302 pounds in 1881.

Properties.—When recently distilled, oil of cloves is somewhat thicker than most other volatile oils, and has a pale-yellow color, but may be obtained colorless by rectification, and becomes thicker, darker, and finally yellowish-brown, on keeping. It has a strong odor of cloves, a burning aromatic taste, and boils at $240^{\circ} C.$ ($455^{\circ} F.$). Its specific gravity varies between 1.034 and 1.056; oil of clove-stalks, though agreeing in odor, has a density of about 1.009. Oil of cloves dissolves freely in alcohol, the solution having a slight acid reaction and yielding with ferric chloride a purplish-blue color. Sulphuric acid colors the oil blood-red, finally blue; and it acquires also a blue or violet color when exposed in a thin layer to bromine vapor; iodine dissolves in it quietly; strong potassa solution converts it into a crystalline mass of eugenate of potassium; a soft yellowish crystalline mass is also obtained on agitating the oil with an equal volume of stronger water of ammonia; fuming nitric acid acts violently upon the oil, sometimes with ignition. The oil is without action or with but slight action (-4° , Gladstone) upon polarized light.

Composition.—On distilling a mixture of cloves with excess of potassa the colorless distillate is the *light oil of cloves*, and has the composition $C_{15}H_{24}$; its odor is distinct from that of cloves—more terebinthinate; it has the density .918, and boils at $251^{\circ} C.$ ($483.8^{\circ} F.$). On decomposing the eugenate of potassium with sulphuric acid and rectifying the separated oil, *eugenic acid* or *eugenol*, $C_{10}H_{12}O_2$, is obtained as a colorless oil having the odor of cloves, the specific gravity 1.076 (Stenhouse), 1.0785 (Pettit), and boiling at $247.5^{\circ} C.$ ($477.5^{\circ} F.$); it yields with bases crystallizable salts, which, with the exception of the barium compound, are decomposed by much water or alcohol, and are colored blue or purple by ferric salts. By fusion with potassa, eugenol is decomposed into protocatechuic and acetic acids. L. C. Pettit (1880) obtained 72 per cent. of eugenol, which became red, and then purple, with sulphuric acid; the potassium compound was found to be soluble without decomposition in alcohol and glycerin, and sparingly soluble in benzin. On boiling acetic anhydride with eugenic acid, *aceto-eugenol*

is formed, and from this compound vanillin may be obtained by treating it carefully with a weak solution of potassium permanganate, rendering the liquid alkaline, concentrating, and acidulating, when the vanillin may be extracted with ether (Tiemann, 1878). By treating eugenic acid in an atmosphere of carbonic acid with sodium, Scheuch (1863) obtained the sodium salt of *eugenic acid*, $C_{11}H_{12}O_4$, which is crystallizable, soluble in water, colors ferric salts deep-blue, and is decomposed by heat into carbonic and eugenic acids. The same author proved likewise the presence in oil of cloves of salicylic acid, most probably in the form of an ether.

Adulterations.—The determination of the boiling-point and the specific gravity are sufficient for detecting most adulterations to which oil of cloves is sometimes subject; on treating the suspected oil with alcoholic solution of potassa the odor of cloves disappears and the nature of the adulteration is established. For the detection of carbolic acid Jacquemin (1875) recommended adding a trace of aniline, shaking with water, and adding a little chlorinated soda, when a blue color will be produced. Flückiger (1870) proposed to shake 1 part of oil with 50 parts of hot water, concentrate the aqueous liquid by evaporation at a moderate heat, add a drop of ammonia and a little chlorinated lime; in the presence of carbolic acid a green color, passing into blue, will be produced. "Hot water, on being agitated with oil of cloves, should not acquire an acid reaction, and after cooling the clear filtrate should not turn blue or green on the addition of a drop of solution of ferric chloride (carbolic acid), but it should become yellow with lime-water. The oil should yield a clear solution with an equal weight or a little more of alcohol spec. grav. .894 (oil of turpentine, copaiva, etc.)."—*P. G.*

Off. Prep.—Confect. scammonii, Pil. colocynth. comp., Pil. colocynth. et hyoscyami. *Br.*

Medical Action and Uses.—The action and uses of oil of cloves are essentially the same as those of the oils of caraway and anise. It is seldom employed internally, but it is sometimes used to allay the pain of *carious teeth* and of *carache*. The dose is from 2 to 5 drops (Gm. 0.10–0.30).

OLEUM CHENOPODII, U. S.—OIL OF CHENOPodium.

Oil of American wormseed, E.; *Essence de chénopode anthelminitique*, Fr.; *Chenopodiumöl*, *Amerikanisches Wurmsamenöl*, G.

The volatile oil is obtained from the fruit of *Chenopodium anthelminticum*, *Linne*.

Nat. Ord.—Chenopodiaceæ (see page 424).

Preparation.—Distillation with water or by means of superheated steam yields this volatile oil. Much of it is distilled in Maryland and in some of the Western States. The fruit yields about 3 to 3½ per cent., the fresh herb ½ to 1 per cent. The Western oil is rather less pungent than the Baltimore oil of wormseed.

Properties.—Oil of wormseed is colorless or yellowish, limpid, becoming brown and thick on exposure. It has the peculiar odor of wormseed and a bitterish, pungent, and somewhat cooling, aromatic taste. Its specific gravity is about .920 (U. S.); when fresh it is .902 to .91, and increases by age to .960. It is readily soluble in alcohol, the solution having a neutral reaction. It boils at 180° to 190° C. (356° to 374° F.), dissolves iodine slowly, and turns brown-red when boiled with nitro-prusside of copper.

Composition.—Garrigues (1854) found oil of wormseed to be a mixture of a hydrocarbon, $C_{10}H_{16}$, and a liquid oxygenated oil, $C_{10}H_{16}O$. The former has the density .932, boils near 176° C. (350.6° F.), and yields a liquid and a crystalline compound with chlorine. The specific gravity of the latter is .987, its boiling-point 245° C. (473° F.).

Medical Action and Uses.—Several cases of poisoning by this oil are recorded. A child six years old took several successive doses of 15 drops each for worms. The symptoms were insensibility, stertor, rattling in the throat, a small, feeble, and frequent pulse, convulsions of one side of the body, cold extremities, and death in 36 hours (*Boston Med. and Surg. Jour.*, xlv, 373). A man aged sixty-three years took an ounce of it in divided doses during 1 day. He fell into a deep sleep, and then into coma, with profuse sweating and salivation. The respiration was 33, the pulse 106, the pupils dilated. Before death, which took place the same day, the respiration rose to 44 and the pulse to 143 (Gable, *Phila. Med. Times*, x, 404). In another case several children took an uncertain dose of the oil. The one most deeply affected was soporose, breathing heavily, and when aroused was very deaf and had severe headache and ringing in the ears. The stupor continued for several days with an aggravation of the several symptoms; pulse 100, respiration 58 (*North. Med. Record*, xviii, 349). A case reported as one of "poisoning by oil of chenopodium" (*Maryland Med. Jour.*, Nov. 1878) appears to us to have been an example of

chronic disease of the brain terminating in softening of that organ. Wormseed oil is chiefly used as an anthelmintic, although occasionally employed for the cure of *intermittent fever, hysteria, chorea*, and other *nervous affections*. In America it is one of the most popular remedies for *lumbroid worms*, but it has also been used successfully to expel *taenia*. It is true that in Europe some observers have tended to discredit its efficacy, and even in this country there is more evidence of its utility in cases of gastro-intestinal *dyspepsia* among children, which is often mistaken for verminous disease, than of its direct vermifuge powers. It may be given to children in *doses* of from 5 to 10 drops (Gm. 0.30–0.60) on sugar, and twice daily for several days, when it should be followed by a dose of castor oil.

OLEUM CINNAMOMI, U. S., Br., P. G.—OIL OF CINNAMON.

Oil of Ceylon cinnamon, E.; Essence de cannelle, Fr.; Zimmtöl, G.

The volatile oil distilled from cinnamon-bark (see page 475).

Preparation.—The British and French Pharmacopœias recognize only the volatile oil of Ceylon cinnamon, which is almost exclusively prepared in Ceylon by distilling the chips and refuse bark with water; the German Pharmacopœia has admitted only the oil of Chinese cinnamon; while the U. S. Pharmacopœia recognizes both volatile oils by the above title. Judging from the custom-house entries, but little of the Ceylon oil is imported into the United States. The importation in 1877 amounted to 15 pounds, in 1881 to 783 pounds, while 20,685 pounds of oil of Chinese cinnamon (or Cinnamon cassia) were imported in 1867, and 104,116 pounds in 1881. The latter oil is sometimes distilled in the United States. Ceylon cinnamon yields $\frac{1}{2}$ to 1 per cent., Chinese cinnamon $\frac{1}{2}$ to $1\frac{1}{2}$ per cent., of volatile oil.

Properties.—OLEUM CINNAMOMI ZEYLANICI.—Oil of Ceylon cinnamon, *E.*; Essence de cannelle de Ceylon, *Fr.*; Zeylonzimmtöl, *G.*—It is a pale-yellow or reddish liquid, becoming red-brown and thicker on exposure, finally separating crystals of cinnamic acid. It has a strong but agreeable cinnamon odor and a sweet and at the same time hot, aromatic taste. Its specific gravity is about 1.035 (1.0097, Jackson, 1882), and increases by age. It remains clear at the freezing-point of water (at $-10^{\circ}\text{C.} = 14^{\circ}\text{F.}$, *U. S. P.*), but at a still lower temperature (at $-20^{\circ}\text{C.} = -4^{\circ}\text{F.}$, Bizio) separates a stearopten; it has no action on polarized light or shows a slight left rotation, is readily soluble in alcohol, sparingly soluble in benzin, and has a neutral reaction on litmus-paper when fresh, and an acid reaction when old. It dissolves iodine almost quietly, and soon forms a thick mass; fuming nitric acid imparts to it a carmine color without causing effervescence; boiling with nitro-prusside of copper turns it red, then dark-brown; its alcoholic solution is somewhat darkened by ferric chloride. Good oil of cinnamon does not congeal when agitated with strong solution of potassa.

OLEUM CINNAMOMI CASSIÆ, s. OLEUM CASSIÆ.—Oil of Chinese cinnamon. Oil of cassia, *E.*; Essence de cannelle de Chine, *Fr.*; Zimmtkassienöl, *G.*—It resembles the preceding oil very closely in all its properties, except that its color is more brownish, its odor less delicate, its taste less sweet, and its specific gravity greater, being usually 1.055 to 1.065 (1.0366, Jackson, 1882); sometimes it is slightly dextrogyre.

Composition.—Both oils contain variable quantities of hydrocarbon, but consist chiefly of *cinnamic aldehyd*, $\text{C}_9\text{H}_8\text{O}$, and when old also resin and cinnamic acid, $\text{C}_9\text{H}_7\text{O}_2$. In its pure state cinnamaldehyd is a colorless oil, heavier than water, combines with strong nitric acid in the cold, forming crystals, which are soluble in alcohol and ether, decomposed by water, and when heated yield oil of bitter almond and benzoic acid. Oxidizing agents generally, when acting upon cinnamaldehyd, generate the odor of bitter almonds, and finally produce benzoic acid; heated with solid potassium hydrate, potassium cinnamate is formed, hydrogen being given off; $\text{C}_9\text{H}_8\text{O} + \text{KHO}$ yields $\text{C}_9\text{H}_7\text{KO}_2 + \text{H}_2$. *Cinnamic acid* crystallizes in shining, colorless prisms, which are inodorous, dissolve freely in alcohol, ether, and boiling water, fuse at about 130°C. (266°F.), boil and volatilize without decomposition at about 295°C. (563°F.), and it is oxidized by chlorinated lime and hot dilute nitric acid to oil of bitter almond and benzoic acid.

Adulterations.—Oil of cinnamon is sometimes mixed with oil of cassia, which is best detected by the difference in their physical properties pointed out above. An adulteration with oil of cloves or oil of cinnamon-leaves cannot be detected by the odor, except on heating, when acrid vapors will be given off. The behavior to ferric chloride, strong potassa solution, and cold fuming nitric acid affords additional means for detection.

“A solution of 4 drops of oil of cinnamon in 10 Cem. of alcohol should, on the addi-

tion of 1 drop of test solution of ferric chloride, give merely a brown but not a green or blue color (carbolic acid, oil of cloves, etc.)."—*P. G.*

Allied Oils.—*OLEUM CINNAMOMI FOLIORUM.*—Oil of cinnamon-leaves, *E.*: Essence de feuilles de cannellier, *Fr.*; Zimmtblätteröl, *G.*—The leaves are distilled in Ceylon with sea-water. The oil is a rather viscid brown liquid, having the specific gravity 1.053 and a strong clove-like and faint nutmeg-like odor; after treatment with potassa the odor resembles that of cinnamon. Stenhouse (1854) found in the oil a terpene and eugenol, with a small quantity of benzoic acid; the latter could not be detected by Schæfer (1882). N. A. Kuhn (1877) showed the presence of cinnamic acid.

OLEUM CINNAMOMI RADICIS.—Oil of cinnamon-root, *E.*: Essence de racine de cannellier, *Fr.*; Zimmtwurzelöl, *G.*—It is yellow, lighter than water, and has an odor like that of a mixture of cinnamon and camphor and a camphoraceous taste.

Off. Prep.—Aqua cinnamomi, Spiritus cinnamomi, *U. S.*

Medical Action and Uses.—Excessive doses of this oil given to rabbits produce violent action of the heart, hurried respiration, distress, evacuation of solid feces, insensibility, slow and labored respiration, cold extremities, and death. The gastro-intestinal mucous membrane is not inflamed. The oil is much employed to give an agreeable flavor to medicinal compounds and render them acceptable to the stomach. If the virtues attributed to cinnamon (see *CINNAMOMUM*) in uterine hæmorrhage are real, they would probably be displayed more efficiently by the oil than by any other preparation of the medicine. The *dose* is 1 or 2 drops (*Gm.* 0.05–0.10).

OLEUM COCOS, *P. G.*—COCOANUT OIL.

Oilum cocois.—Cocoanut butter, *E.*; *Beurre de coco*, *Fr.*; *Kokosnussöl*, *G.*

From *Cocos nucifera*, *Linneë*.

Nat. Ord.—*Palmae*.

Origin.—The cocoanut tree is now met with in all tropical countries. It grows to a height of 70 or 80 feet (21–24 *M.*), and has at the apex a tuft of leaves which are 12 feet (3.6 *M.*) and more long and have numerous narrow rigid and long leaflets. The yellowish-white flowers produce the well-known cocoanuts, which in their unripe state contain a sweetish liquid. The seeds contain much fixed oil, which is obtained by hot pressure or on being boiled in water. The seeds of *Cocos butyracea*, *Linneë*, of Brazil, yield a similar oil. Nearly 267,000 gallons of cocoanut oil were imported into the United States in the year 1876–77, and nearly 1,000,000 gallons in 1882, principally from Ceylon.

Properties.—Cocoanut oil is of a butyraceous consistence, white, and has a peculiar not agreeable odor, which is also observed in the soap prepared with it; its taste is mild and bland, but on exposure to the air it becomes rancid and acquires an acrid taste. Its melting-point varies between 22° and 28° or 30° C. (71.6°–82.4°–86° F.); the cold pressed oil melts at 20° C. (68° F.) or less. The fused, thin, transparent, yellowish oil congeals between 18° and 12° C. (64.4° and 53.6° F.). After having been heated to 240° C. (464° F.) it remains liquid for several days. The oil is readily saponified at a low temperature, the soap being white, hard, and capable of uniting with much water near 18° C. (64.4° F.).

Composition.—By cold pressure it may be separated into a liquid and solid portion, both of which are glycerides. According to Gorgey and Oudemans, the acids contained in cocoanut oil are palmitic and myristic, but principally lauric acid, together with caprylic, caprylic, and capronic acids.

Medical Action and Uses.—Cocoanut oil has been tried as a substitute for cod-liver oil, but, like other succedanea for that product, was found inefficient. It was given in doses of a tablespoonful (*Gm.* 16). It is chiefly valuable for its economical and pharmaceutical uses.

OLEUM COPAIBÆ, *U. S., Br.*—OIL OF COPAIBA.

Oilum balsami copaivæ.—Essence de copahu, *Fr.*; *Copaibaöl*, *G.*

The volatile oil distilled from copaiba (see page 503).

Preparation.—The oil is obtained by distilling copaiba with water, a metallic still being preferable to a glass retort; a considerable quantity of water, or preferably steam, should be used, or the distilled water returned to the still until all the oil has been

obtained. All that is consumed in the United States is prepared here from Para copaiba, which yields 50 to 60 per cent., or even more.

Properties.—Oil of copaiba is limpid, colorless, or pale-yellowish, and on exposure becomes slowly thicker and yellow. It has the odor of copaiba, a pungent bitterish taste, neutral reaction to test-paper, spec. grav. .88 to .91, and boils at about 250° C. (482° F.). It is soluble in an equal weight of alcohol (*U. S. P.*), dissolves in about 40 parts of alcohol spec. grav. .85, mixes with iodine without violent reaction, and yields with hydrochloric acid gas a liquid and a crystallizable compound. It deviates polarized light to the left.

Composition.—The oil has the elementary composition of oil of turpentine, and consists of several isomeric modifications of $C_{15}H_{24}$, differing in boiling-point, in the behavior to polarized light, and probably in other properties.

Adulterations.—The addition of oil of turpentine is detected by the odor and by the more violent reaction with iodine.

Medical Action and Uses.—Oil of copaiba is poisonous to rabbits in doses of an ounce or more. The symptoms produced by it are hurried breathing, palpitation, restlessness, frequent micturition, diarrhoea with mucous or bloody stools, and death by asthenia. After death a partial destruction of the gastro-intestinal epithelium is the only lesion observed. Upon the human skin it acts very feebly as an irritant. When taken internally it is excreted by the urine, which then furnishes a precipitate with nitric or muriatic acid. It is very doubtful whether this oil has any efficient control over *gonorrhœa*, the disease for which copaiba itself is chiefly employed. It probably is more useful in chronic pulmonary catarrh or *chronic bronchitis*, since it is apparently through the lungs that the odorous constituent of all oleoresins is eliminated. But clinical evidence upon this point is wanting, unless, indeed, the negative proof afforded by the silence of all competent authorities be accepted as sufficient. The *dose* of the oil is from 10 to 15 drops (Gm. 0.60–1).

OLEUM CORIANDRI, *U. S., Br.*—OIL OF CORIANDER.

Essence de coriandre, Fr.; *Korianderöl*, G.

The volatile oil distilled from the fruit of *Coriandrum sativum*, *Linné*.

Nat. Ord.—Umbelliferae (see page 509).

Preparation.—Coriander-fruit is ground, and then distilled with water or by means of steam. The yield varies between $\frac{1}{2}$ and 1 per cent.

Properties.—It is colorless or pale-yellow, has a mild and agreeable aromatic odor and taste of coriander, a spec. grav. of .86 to .87, commences to boil at about 150° C. (302° F.), and dissolves readily in alcohol. Iodine and fuming nitric acid act energetically upon it, the latter producing a greenish resin.

Composition.—The oil has the composition $C_{10}H_{16}O$, and is isomeric with borneol. From Kawalier's investigations (1852) it appears sometimes to contain also a hydrocarbon, $C_{10}H_{16}$.

Adulteration.—Leonhardi (1878) mentions oil of orange, which is detected by its insolubility in an equal bulk of 85 per cent. alcohol.

Off. Prep.—Syrupus sennæ, *Br.*

Medical Action and Uses.—Like oil of anise, fennel, etc., this oil is aromatic and carminative, and is used in flatulent *colic*, to relieve the pain of *rheumatism*, *neuralgia*, etc., and to mitigate the griping operation of certain purgatives. It corrects the odor and taste of fluid extract of senna better than any other aromatic. *Dose*, 1 to 5 drops (Gm. 0.05–0.25).

OLEUM CUBEBAE, *U. S., Br.*—OIL OF CUBEBA.

Oleum cubebarum.—Oil of cubebs, *E.*; *Essence de cubèbe*, Fr.; *Kubenöl*, G.

The volatile oil distilled from the fruit of *Cubeba officinalis*, *Miquel* (nat. ord. Piperaceæ).

Preparation.—Cubebs are ground, and then distilled with steam or with water, when repeated cohobation is necessary. The yield is about 10 per cent., but varies considerably with the quality of the fruit. It is distilled in the United States, little being imported—558 pounds in 1867, none in 1876, and only 5 pounds in 1877.

Properties.—Oil of cubebs has a greenish or yellowish tint, but after rectification is colorless, and on exposure becomes thick like olive oil. It has the odor of cubebs, a

warm, camphoraceous, aromatic taste, spec. grav. .92, a neutral reaction, boils at about 250° C. (482° F.), dissolves in 25 parts of alcohol sp. gr. .85, and turns polarized light to the left. Iodine dissolves in the oil quietly, but evolves some vapors; concentrated sulphuric acid colors it yellow, and, on warming, red.

Composition.—Oghialoro (1875) showed the oil to be a mixture of three levogyrate hydrocarbons, of which one is $C_{10}H_{16}$, is present in small quantity and boils between 158° and 163° C. (316.4° and 325.4° F.); the remaining two have the composition $C_{15}H_{24}$, and boil between 262° and 265° C. (503.6° and 509° F.); only one of these yields a crystallizable compound with HCl, melting at 118° C. (244.4° F.). At a low temperature the oil sometimes separates inodorous crystals of *cubeb camphor*, which has the formula $C_{30}H_{48} \cdot 2H_2O$, and fuses at 65° C. (149° F.).

Medical Action and Uses.—In the dose of an ounce oil of cubeb produces symptoms in rabbits almost identical with those of oil of copaiva, but more strongly marked. In man it causes, occasionally, an eruption, as copaiva does. It displays no curative virtues in gonorrhœa. The *dose* is from 10 to 15 drops (Gm. 0.60–1) or more.

OLEUM ERIGERONTIS CANADENSIS, U. S.—OIL OF CANADA ERIGERON.

The volatile oil distilled from the fresh flowering herb of *Erigeron canadense*, Linné.

Nat. Ord.—Compositæ.

Preparation.—The fresh herb (see page 586) is distilled in the United States with water or by means of steam.

Properties.—Oil of erigeron is a limpid, pale-yellow liquid of a peculiar aromatic, persistent odor, somewhat like that of hemlock (*Abies canadensis*), and of an aromatic not very pungent taste. It has the spec. grav. .845, and commences to boil at about 155° C. (311° F.), the boiling-point rising to 185° C. (365° F.); the redistilled oil is colorless, and neutral to test-paper. It dissolves iodine without explosion, is gradually colored reddish by potassa, and slowly acted on in the cold by fuming nitric acid. The oil becomes thick and reddish-brown by age, dissolves freely in ether and absolute alcohol, but is only moderately soluble in 80 per cent. alcohol.

Composition.—The oil contains oxygen, as ascertained by Procter (1854), but, according to Beilstein and E. Wiegand (1882), it consists mainly of a terpene, $C_{10}H_{16}$, boiling at 176° C. (349° F.), and yielding a crystalline compound with HCl, which melts near 48° C. (118.4° F.).

Medical Action and Uses.—This oil has had a certain reputation for controlling *uterine hæmorrhage*, and the plant from which it is derived was held by the aborigines to quicken *uterine contractions*. The evidence respecting its virtues is conflicting, and seems, on the whole, not adapted to inspire much confidence. Like other nervo-vascular stimulants, it is said to have been useful in the *typhoid state*. The *dose* is from 5 to 10 drops (Gm. 0.30–0.60).

OLEUM EUCALYPTI, U. S., Br.—OIL OF EUCALYPTUS.

Essence d'eucalyptus, Fr.; *Eucalyptusöl*, G.

The volatile oil distilled from the fresh leaves of *Eucalyptus globulus* or *Eucalyptus amygdalina*, Labillardière, and some other species of *Eucalyptus*.

Nat. Ord.—Myrtaceæ.

Origin and Preparation.—The first species mentioned above is described on page 593. The second species, which in Australia is known as *peppermint tree*, sometimes attains a height of over 400 feet (120 M.), and, being more accessible, its foliage is frequently subjected to distillation with water, and the volatile oil thus obtained is sold as eucalyptus oil. Bosisto states (see *Am. Jour. Phar.*, 1876, p. 372) that 1000 pounds of the fresh leaves of the following species yield the quantities of oil stated: *E. obliqua*, L'Heritier, called *stringy bark*, 80 oz.; *E. globulus*, Labillardière, 120 oz.; *E. sideroxylon*, Bentham, called *iron bark*, 160 oz.; *E. oleosa*, Mueller, known as *mallee*, 200 oz.; while *E. amygdalina* yields 500 oz. of volatile oil.

Properties.—These volatile oils are colorless or pale-yellow, thin liquids, becoming thicker and somewhat darker by age. They are neutral to test-paper, are highly and more or less pungently aromatic in odor and taste, that of *E. globulus* being camphoraceous, that of *Eu. amygdalina* somewhat resembling peppermint, while others have a more terebinthinate or lemon-like odor, and that of *Euc. persicifolia*, or *peach gum*, like oil of

bitter almonds, with which it agrees in containing hydrocyanic acid. The specific gravity of these oils varies between .88 and .94, and their boiling-points between about 130° and 200° C. (266° and 392° F.).

Composition.—The dextrogyre oil of *E. globulus* was examined by Cloëz (1870) and by Faust and Homeyer (1874). Cloëz regarded the oil as being chiefly composed of *eucalyptol*, $C_{12}H_{20}O$, boiling at 178° C. (352.4° F.), and yielding with phosphoric anhydride two compounds, $C_{12}H_{18}$, of which *eucalyptene* boils at 165° C. (329° F.), and *eucalyptolene* at above 300° C. (572° F.). Faust and Homeyer, however, obtained from the oil about 60 per cent. of a *terpene*, $C_{10}H_{16}$, boiling between 172° and 175° C. (342.6° and 347° F.), 30 per cent. of *cymol*, $C_{10}H_{14}$, the remainder being a *terpene* boiling at 150° C. (302° F.), and an oxygenated compound, probably $C_{10}H_{16}O$, which they named *eucalyptol*, Cloëz's compound of the same name being a mixture of the first two hydrocarbons, which rapidly combine with oxygen. The oil of *E. amygdalina* does not appear to contain eucalyptol.

Action and Uses.—For an account of the virtues ascribed to this oil the reader is referred to the article *EUCALYPTUS*. The *dose* of the oil is from 2 to 5 drops.

OLEUM FENICULI, U. S., P. G.—OIL OF FENNEL.

Essence de fenouil, Fr.; *Fenchöl*, G.

The volatile oil distilled from the fruit of *Fœniculum vulgare*, *Guertner* (see p. 709).

Nat. Ord.—Umbelliferae.

Preparation.—Bruised fennel is distilled with water, or, preferably, by means of superheated steam. The yield is about 3½ or 4 per cent. The oil used in the United States is chiefly procured from Germany and France, from 800 to 1000 pounds being annually imported.

Properties.—Oil of fennel is colorless or yellowish, has a neutral reaction, an agreeable fennel odor, a sweetish aromatic taste (*oil of sweet fennel*), and is of the spec. grav. .96 to .99 (not less than .960, *U. S., P. G.*); it congeals below 10° C. (50° F.), sometimes not until cooled below the freezing-point of water, and Zeller obtained an oil which remained liquid at -20° C. (-4° F.); moreover, the congealing-point of the oil becomes lower by age. An oil which does not congeal between 5° and 10° C. (41° and 50° F.), as required by the Pharmacopœia, cannot, for this reason alone, be considered impure. (See also *OL. ANISI*.) Boiled with nitro-prusside of copper, oil of fennel turns yellowish-brown or red-brown; on the addition of iodine it becomes thick like an extract, or even brittle. It is soluble in alcohol in all proportions, and turns the ray of polarized light to the right.

Composition.—The difference in the physical properties is due to the variable proportion of liquid and solid *anethol* contained in it. (See *OL. ANISI*.) The oil also contains a hydrocarbon isomeric with oil of turpentine.

Tests.—The solution in alcohol should not become dark-colored on the addition of a little ferric chloride (phenol, etc.). 1 drop of the oil, triturated with sugar and afterward with 500 Gm. of water, should impart to the latter the pure flavor of fennel (other volatile oils).—*P. G.*

Off. Prep.—Aqua fœniculi, Spiritus juniperi comp., *U. S.*

Medical Action and Uses.—The action of fennel oil when given to animals in large doses appears to be identical with that of oil of anise. Its medicinal operation closely resembles that of the same oil. It is used in *flatulent* disorders and to qualify the action of harsh purgatives, and is sometimes employed as a *galactagogue* and as an *emmenagogue*. The *dose* is from 5 to 10 drops (Gm. 0.30–0.60).

OLEUM GAULTHERIÆ, U. S.—OIL OF GAULTHERIA.

Oil of wintergreen, E.; *Essence de gaulthérie*, Fr.; *Wintergreenöl*, G.

The volatile oil distilled from the leaves of *Gaultheria procumbens*, *Linné* (see p. 724).

Nat. Ord.—Ericaceæ.

Preparation.—The entire plant is generally collected, and while fresh distilled with water or with the aid of steam. It is largely made in New York, Pennsylvania, and some of the New England States. The average yield is about .5 per cent., and varies between .4 and .8 per cent. G. W. Kennedy (1882) showed that much of the commercial oil of wintergreen is obtained from *Betula lenta* (see page 317), the young shoots being distilled after having been cut into short pieces and subjected to brief maceration with water; the yield is about .23 per cent.

Properties.—Oil of gaultheria is usually of a reddish color, but may be obtained colorless by rectification. According to I. E. Leonard (1884), the color is usually due to the presence of a little iron, and is readily removed by citric acid. It has a strong and agreeable aromatic odor and a sweetish, warm, aromatic taste, and begins to boil at a little above 200°C . (392°F .). It is the heaviest of the volatile oils, its density being 1.180 at 15°C ., which is also that of oil of sweet birch. Occasionally, oil of gaultheria is lighter (1.170), in consequence of containing a light hydrocarbon, but the extent of this variation has not been fully determined. The oil is neutral or faintly acid to test-paper; has a slight dextrogyre rotation, and dissolves readily in alcohol and but to a small degree in water; the solutions acquire a dark-purple color on the addition of ferric chloride. The pure oil is not colored on the addition of strong nitric acid, but soon congeals into colorless crystals of a nitro-compound. A solid crystalline mass is also obtained on agitating the oil with concentrated solution of potassa or soda.

Composition.—Procter (1842) recognized the presence in this oil of salicylic acid. Cahours subsequently (1843) proved it to consist to the amount of about 90 per cent. of *methylsalicylic acid* (methyl salicylate or *mono-methylsalicylic ether*), $\text{CH}_3\text{C}_7\text{H}_5\text{O}_3$, which with some other salicylic ethers is now also artificially prepared for use in the arts. H. P. Pettigrew (1883) showed the oil of sweet birch to be pure methyl salicylate, to boil constantly at 218°C . (424.4°F .), and on saponification to yield methyl alcohol and salicylic acid. Pure methyl salicylate is a colorless oil, has the spec. grav. 1.18, boils at 222°C . (431.6°F .) (Cahours), and forms crystalline compounds with the alkalis. The remaining constituent of oil of wintergreen—of which Pettigrew (1884) obtained only 0.3 per cent.—is *gaultherilene*, a colorless thin hydrocarbon of the formula $\text{C}_{10}\text{H}_{16}$, boiling at 160°C . (320°F .), and having a strong peculiar odor, described as pepper-like by Cahours. Volatile oils of similar composition have been obtained from *Gaultheria hispida*, *G. punctata*, *G. leucocarpa*, *Polygala pauciflora*, and *Monotropa Hypopitys*.

Adulterations.—The great density of this volatile oil prevents its adulteration with most cheaper ones, which would reduce its specific gravity. A mixture of alcohol and chloroform has been employed for the purpose, but is readily detected by the low boiling-point and the character of the first fractional distillate. The most common adulterant is oil of sassafras, which is colored dark-red and converted into a brown-red resinous mass by strong nitric acid. The pure oil yields nearly colorless crystals of *methyl nitrosalicylate*. "When heated to about 80°C . (176°F .) the oil should not yield a colorless distillate having the characteristics of chloroform or of alcohol. On mixing 5 drops of the oil with 5 drops of nitric acid the mixture should not acquire a deep-red color, and should not solidify to a dark-red, resinous mass (absence of oil of sassafras)." — *U. S.*

Off. Prep.—*Spiritus gaultheriæ*, *Trochisci morphinæ et ipecacuanhæ*, *U. S.*

Medical Action and Uses.—Its action in large doses closely resembles that of the other aromatic essential oils. In the case of a boy nine years old $\frac{1}{2}$ ounce (Gm. 16) of it occasioned vomiting, purging, epigastric pain, fever, labored and slow respiration, dulness of hearing, and an uncontrollable desire for food. Two girls, fourteen and fifteen years old, drank, the one about an ounce, the other about 2 ounces, of the oil. Both were seized with vertigo, weakness, hot skin, frequent pulse, cold sweats, labored breathing, and dulness of hearing. In the elder there was inability to speak, with cramp in the epigastrium and convulsions. The younger patient recovered; the elder died in about 10 hours from congestion of the brain and convulsions. The odor of gaultheria was perceived in the perspiration and the breath had a pungent odor (Fichtner, *Med. News*, Nov. 1881, p. 698).

In 1880, Perier made use of a mixture of essence of wintergreen and tincture of quilaia in the local treatment of chronic cystitis, and a 1 per cent. solution of the former in vaseline as an antiseptic (*Med. Record*, xviii. 262). In 1881, Gosselin and Bergeron determined that, like alcohol and salicylic acid, this oil prevents putrefactive fermentation, and that when duly diluted with an alcoholic solution it does not irritate the tissues, but hastens the healing of their wounds and other lesions. These surgeons made use chiefly of a solution consisting of 100 parts each of alcohol and water, with $2\frac{1}{2}$ parts of oil of gaultheria (*Archives gén.*, Jan. 1881, p. 16). The large proportion of methyl salicylate contained in the oil naturally led to its employment in *rheumatism*. It was apparently first used for this purpose by Mr. Casamayor of Brooklyn, N. Y. (*Ephemeris*, i. 30), and next by Dr. Kinnicutt of New York (*Med. Record*, xxii. 505). Twelve cases of acute [articular] rheumatism treated by the latter gave an average duration of the pyrexia of $3\frac{1}{2}$ days; of the joint pains, $4\frac{1}{2}$ days; of the stay in hospital, $24\frac{1}{2}$ days. The oil was given at first in doses of 10 minims every 2 hours until eight doses had been taken, and

afterward the doses were increased as well as their frequency. The reporter believes that his cases presented less than the usual proportion of heart-complications, but if so the oil must differ in its effects from its active element, salicylic acid. Dr. Austin Flint (*Phila. Med. Times*, xiii. 846) and Dr. Gottheil (*Med. Record*, xxiv. 258) have reported analogous results. It is sometimes used as a carminative, but most frequently to conceal the taste of nauseous medicines. It assists in flavoring the compound syrup of sarsaparilla. The dose may be stated at 5 or 10 drops (Gm. 0.30–0.60). This oil may be given in powdered sugar, or floated on water, or in gelatin capsules. It does not readily cause disgust.

OLEUM GOSSYPH SEMINIS, U. S.—COTTON-SEED OIL.

Oleum gossypii.—Cotton oil, E.; *Huile de coton*, *Huile de semences de cotonnier*, Fr.; *Baumwollsam-enol*, G.

A fixed oil expressed from the seed of *Gossypium herbaceum*, Linné, and of other species of *Gossypium*, and subsequently purified.

Nat. Ord.—Malvaceæ.

Origin and Preparation.—(For remarks on the cotton-plant see page 743). After the seeds have been deprived of the cotton they are about $\frac{1}{8}$ inch (8 Mm.) in length and $\frac{1}{4}$ inch (4 Mm.) in width, of an irregular ovoid shape, have a brown, hard, somewhat brittle testa with a prominent raphe along its entire length, and contain a whitish embryo with large, folded cotyledons and numerous blackish resin-glands imbedded in its tissue. For obtaining the oil the testa is crushed in a suitable machine and removed by winnowing; the kernels (embryo) are then ground, and, enclosed in bags, are subjected to hydraulic pressure. A bushel of seeds yields about 2 gallons of oil, or, by weight, 100 parts of seeds give shells and cotton-fibre 47, press-cake 38, and oil 15 parts. The air-dry seeds contain oil 21.5, albuminoids 28, other organic substances 33.5, ash 9, and water 8 per cent. The average composition of the press-cakes is oil 7.5, albuminoids 20, other organic compounds 51, ash 8.5, and moisture 13 per cent.

Purification.—The crude oil is of a more or less deep-brown color, turbid, thickish, and contains a large percentage of albuminous matter. On standing, a portion of the impurities subside, and the oil, now termed “clarified,” becomes clear and of an orange color. On treating it with boiling water or superheated steam the albuminoids are coagulated, and a still lighter colored or refined oil is obtained. The final bleaching is effected by agitating the oil well with a small portion of alkali solution and heating.

Properties.—Bleached cotton-seed oil is perfectly transparent, and has a pale straw-yellow color, a bland nut-like taste, and a neutral reaction. Its specific gravity at 15° C. (59° F.) is .925–.927 (.920–.930 U. S. P.); that of the crude oil, .930–.932. It is very sparingly soluble in alcohol, but dissolves readily in ether, chloroform, benzine, etc. Near 5° C. (41° F.) the oil begins to deposit palmitin, but it does not congeal until cooled to –1° or –2° C. (30° or 28.4° F.). Exposed to the air, the oil gradually thickens, but it does not solidify; by the elaidin test it is converted into a yellow or brownish soft mass. Sulphuric acid, sp. grav. 1.75 or more, imparts at once a dark-red or brown color, and gradually forms a thick jelly-like mass; weaker sulphuric acid applied in the cold causes a deeper yellow or orange color. Nitric or hydrochloric acid scarcely affects the color, but fuming nitric acid colors orange-brown. Warmed with concentrated solution of zinc chloride, a brown color is produced. When agitated with concentrated solution of lead subacetate, S. S. Bradford (1882) noticed after some time the production of a red tint, and considers this behavior as a reliable test for the detection of cotton-seed oil in olive oil. The oil is readily saponified by strong solutions of alkali, with the exception of a bright-yellow coloring matter, which may be obtained by agitating the soap with benzine.

Composition.—Cotton-seed oil consists chiefly of olein and palmitin, and about 1.8 per cent. of a bright-yellow liquid hydrocarbon. According to O. Bach (1883), the fatty acids of this oil melt at 38° C. (100.4° F.) and congeal again at 35° C. (95° F.). From that portion of the oil saponified in the bleaching process F. Kuhlmann (1861) obtained a pigment by heating the soapy sediment with 4 per cent. of sulphuric acid for several hours to 100° C. (212° F.), washing with water, and dissolving in alcohol. This *cotton-seed blue*, $C_{17}H_{24}O_4$, is amorphous, readily destroyed by oxidizing agents, insoluble in water, diluted acids, and alkalies, sparingly soluble in carbon disulphide and chloroform, soluble in 77 parts of alcohol and 8.4 parts of ether, and dissolves with a purple color in sulphuric acid; it is bleached on exposure to light and air.

Pharmaceutical Uses.—The oil is used by the U. S. P. for liniments in the place of olive oil.

Allied Oils.—**OLEUM FAGI.**—Beech oil, *E.*; Huile de faïnes, *Fr.*; Buchelöl, Bucheckeröl, *G.*—The fruit of the European beech tree, *Fagus sylvatica*, *Linné* (nat. ord. Cupuliferæ), is in some parts of Europe used for the preparation of oil, of which, after the removal of the integuments, about 22 per cent. is obtained. The press-cake is said to have a deleterious effect when eaten by cattle or horses, but is used for feeding hogs and poultry. The oil is yellow and of a mild odor and taste, or, if expressed with heat, somewhat acrid, but becomes mild by age. It does not easily turn rancid, has the spec. grav. .921 to .923, congeals at about -17.5° C. ($.5^{\circ}$ F.), consists mainly of olein with little palmitin and stearin, and behaves to nitric, fuming nitric, and sulphuric acids in a similar manner as cotton-seed oil, but assumes a flesh color with zinc chloride. On saponification it yields a rather soft soap.

OIL OF BRAZIL NUTS. *Bertholletia excelsa*, *Humboldt et Bonpland* (nat. ord. Lecythidaceæ), is a large tree indigenous to Brazil, where it is known as *castanheiro de Para*. The globular fruit is about 10 inches (25 Cm.) in diameter, and contains sixteen to twenty seeds, called *Brazil nuts* or *Para nuts*—*Chataigne du Brésil*, *Fr.*; *Paranuss*, *G.* These are $1\frac{1}{4}$ to 2 inches (3–5 Cm.) long, three-edged, convex upon the back, have a rough, brown-gray, hard testa, and contain a white kernel of an almond-like taste and yielding about 60 per cent. of fixed oil. This is pale-yellow, bland, easily turns rancid, congeals at -1° C. (30° F.), becomes red and red-brown by sulphuric acid and rose-colored by zinc chloride, and consists of olein with palmitin and stearin. A similar oil is yielded by the *Sapucaia nuts*, the seeds of *Lecythis Zabucajo*, *Aublét*, of Brazil.

Uses.—This oil has been substituted for olive-oil in several official preparations, and may be employed in all the surgical manipulations in which the latter was originally used.

OLEUM HEDEOMÆ, U. S.—OIL OF HEDEOMA.

Oil of pennyroyal, *E.*; *Essence de pouliot américain*, *Fr.*; *Poleiöl*, *G.*

The volatile oil distilled from the fresh herb of *Hedeoma pulegioides*, *Linné*.

Nat. Ord.—*Labiata*.

Preparation.—The fresh herb (p. 758) is distilled with water or by means of steam.

Properties.—The oil is a limpid, colorless, or yellowish volatile liquid of a peculiar pungent, mint-like odor and taste, and has a specific gravity of .94 to .95. It has a neutral reaction, is readily soluble in alcohol, and dissolves iodine with a brisk explosive reaction, yielding a viscous liquid. A mixture of the oil with chloral hydrate and sulphuric acid acquires a brownish-green color.

Fresh European pennyroyal (*Pouliot*, *Fr.*; *Polei*, *G.*), *Mentha Pulegium*, *Linné*, s. *Pulegium vulgare*, *Miller* (*Bentley and Trimen, Med. Plants*, 201), yields about 1 per cent. of a volatile oil having a similar odor, according to Kane a density of .925 to .927, a boiling-point near 185° C. (365° F.), and the composition $C_{10}H_{16}O$. The volatile oil of *Pulegium micranthum*, *Claus*, of Southern Russia, examined by *Buttlerow* (1854), has the same composition, but a greater density and higher boiling-point.

Composition.—Oil of hedeoma contains oxygen, but its exact composition has not been ascertained.

Medical Action and Uses.—It has essentially the same action and virtues as the associated volatile oils; that is to say, it is an aromatic stimulant, carminative, and emmenagogue under fit conditions, and is added to embrocations to increase their anodyne and rubefacient action. The *dose* is from 2 to 10 drops (Gm. 0.10–0.60).

OLEUM JUNIPERI, U. S., Br., P. G.—OIL OF JUNIPER.

Oleum fructus (vel baccæ) juniperi.—*Oil of juniper-berries*, *E.*; *Essence de genièvre*, *Fr.*; *Wachholderbeeröl*, *G.*

The volatile oil distilled from the fruit of *Juniperus communis*, *Linné* (see p. 850).

Nat. Ord.—*Conifera*.

Preparation.—Ripe or nearly ripe juniper-berries are well bruised, mixed with table-salt and water, and distilled either over the naked fire or by the aid of steam. The yield is usually $\frac{1}{2}$ to $\frac{3}{4}$ per cent., and sometimes exceeds 1 per cent. Over 7000 pounds are annually imported from Europe into the United States; in 1878, only 2813 pounds.

Properties.—Oil of juniper-berries is colorless or pale greenish-yellow, limpid, but on exposure rapidly thickens and turns yellow, and ultimately reddish-brown, at the same time acquiring an acid reaction; the fresh-distilled oil from old juniper-berries is thickish and light-yellow. Its specific gravity is about .870, but varies between .85 and .90; it begins to boil at 155° C. (311° F.), or if obtained from ripe berries at 205° C. (401° F.) (*Blanchet*), has the peculiar odor of the berries, and a warm, aromatic, somewhat sweetish and terebinthinate taste, shows a neutral reaction to test-paper, turns polarized light

slightly to the left, and is slightly soluble in alcohol, forming with 10 or 12 parts of 80 per cent. alcohol or with 2 or 3 parts of official alcohol a more or less turbid solution; but it yields clear mixtures with carbon disulphide in all proportions. Iodine dissolves slowly in the limpid oil, but acts more energetically upon the thickened oil, sometimes producing fulmination; sulphuric acid colors it brown and red. Old oil of juniper contains formic acid, from which it may be freed by sodium carbonate and rectification.

Composition.—The oil is a mixture of hydrocarbons of the general formula $C_{10}H_{16}$, which differ in their boiling-point (see above), a portion boiling at $282^{\circ} C.$ ($539.6^{\circ} F.$) (Soubeiran and Capitaine). It yields with hydrochloric acid gas a liquid compound.

Adulteration.—The similarity of oil of juniper and oil of turpentine in specific gravity, boiling-point, and behavior to solvents and reagents renders the detection of an adulteration with the latter rather difficult, except by the formation of a solid compound with hydrochloric acid gas, and by its different odor, particularly after exposure. "1 drop of the oil, triturated with sugar and agitated with 500 Gm. of water, should not impart a sharp taste to the latter."—*P. G.*

The oil of *juniper-wood*, obtained by distillation with water, has a different, more terebinthinate odor, and is at first limpid and colorless, but on exposure becomes thick, yellow, and finally dark-brown.

OLEUM JUNIPERI EMPYREUMATICUM, s. Oleum cadinum—Oil of cade, *E.*; Huile de cade, *Fr.*; Kadeöl, *G.*—is an empyreumatic, dark-brown, tar-like liquid obtained from the wood of *Juniperus Oxycedrus*, *Linné*. The empyreumatic oil of common juniper-wood is said to be frequently sold in its place.

Off. Prep.—Spiritus juniperi, *U. S., Br.*; Spiritus juniperi comp., *U. S.*

Medical Action and Uses.—Oil of juniper is stomachic, carminative, and diuretic. In large doses it occasions in animals the same effects upon the nervous and vascular systems as other essential oils, with the addition of diuresis. The last-mentioned operation is evident in man as an effect of medicinal doses. It reddens, and may even blister, the skin. It is an efficient ingredient of diuretic infusions and mixtures, is much used to promote urination in the form of Holland gin, and when inhaled from an atomized solution its diuretic virtues are sometimes promptly and distinctly manifested. The dose is from 5 to 15 drops (Gm. 0.30–1).

Oil of cade is extensively used in Europe in the treatment of *psoriasis*, *pityriasis rubra*, *chronic eczema*, *prurigo*, etc. It is applied either in liniments or in soft potash soaps, pure or dissolved in alcohol. The preparations have the same effect as the analogous ones made with tar, but are less irritating, have less smell, and are less injurious to the clothing. Oil of cade has been given internally as an anthelmintic.

OLEUM LAVANDULÆ, *U. S., Br., P. G.*—OIL OF LAVENDER.

Essence de lavande, *Fr.*; *Lavendelöl*, *G.*

The volatile oil distilled from *Lavandula vera*, *De Candolle* (see p. 875).

Nat. Ord.—Labiatae.

Preparation.—Oil of lavender is distilled in Great Britain and France from the flowers alone or from the flowering-tops or the entire plant, steam heat being usually resorted to. The flowers yield about $\frac{1}{2}$ per cent. of the oil; the quantity, however, varies, and seems to increase in plants grown in southern localities. Stem and leaves yield a small portion of less fragrant oil. The title given above means in the British and German Pharmacopœias the oil of lavender-flowers, while the *U. S. P.* recognizes by it the oil distilled from the flowering-tops or the whole herb. 32,443 pounds were imported into the United States in 1877, and 54,930 pounds in 1882.

Properties.—The oil is very limpid, colorless, yellowish or greenish-yellow, and neutral, and acquires by age an acid reaction and viscid consistence. Its specific gravity is near .890, but varies between .87 and .91; it commences to boil at about $185^{\circ} C.$ ($365^{\circ} F.$), dissolves in its own weight of alcohol specific gravity .835 to .850, and yields clear mixtures with all proportions of strong alcohol and with acetic acid of 90 or more per cent. It has a levogyre action, reacts briskly and with some detonation on the addition of iodine, and acquires a brown color when agitated with corrosive sublimate. Exposed to a low temperature, it sometimes separates stearopten. Its fragrance varies with the part of the plant used for distillation; its taste is bitterish and pungent. The better quality is known in commerce as oil of garden lavender.

OLEUM LAVANDULÆ FLORUM, *U. S.*—Oil of lavender-flowers, *E.*—has the same prop-

erties, but a much more agreeable odor; the U. S. P. directs this oil to be used for preparing Spiritus lavandulæ, Spiritus odoratus, and Spir. ammoniæ aromaticus.

Composition.—The most volatile portion is a hydrocarbon of the formula $C_{10}H_{16}$. The stearopten is stated by Dumas to be identical with camphor. According to Lallemand (1859), the terpene boils at $175^{\circ} C.$, and a second one between 200° and $210^{\circ} C.$ (392° and $410^{\circ} F.$); the oxygenated fraction of the oil contains acetic, and probably also valerianic, acid in combination as ethers. Bruylants (1879) found the terpene to boil at $162^{\circ} C.$ ($323.6^{\circ} F.$), and ascertained the presence of formic and acetic acids, of 10 per cent. of resin, and of 65 per cent. of borneol and camphor. Shenstone (1882) ascertained that the boiling-point of the terpene is raised by continued heating, and suggests that the oxygenated compound is not camphor, but easily converted into it by oxidizing agents.

Adulteration.—The admixture of oil of turpentine is detected by the decreased solubility in alcohol. Oil of spike lavender has a deeper green-yellow color and a more terebinthinate, camphoraceous odor, but agrees with oil of lavender in solubility; according to Lallemand, it contains a dextrogyre hydrocarbon boiling at $175^{\circ} C.$ ($347^{\circ} F.$), and a stearopten apparently identical with camphor; but Bruylants (1879) regards it as differing from oil of lavender, mainly in containing a larger proportion of terpene. Alcohol which may be present as an adulteration is recognized in the distillate obtained at about $80^{\circ} C.$ ($176^{\circ} F.$).

Off. Prep.—Liniment. camphoræ comp., Br.; Tinctura lavandulæ comp., U. S. Br.

Medical Action and Uses.—This preparation is very seldom used alone, although it may be used to calm nervous headache by rubbing a few drops of it upon the temples or by its internal use in the dose of 4 or 5 drops (Gm. 0.30). Its carminative and general stimulant operation is usually obtained through the simple and compound spirit of lavender.

Oil of lavender-flowers is more fragrant than the oil distilled from the herb and flowers, but its action, uses, and dose are about the same.

OLEUM LIMONIS, U. S., Br.—OIL OF LEMON.

Oleum citri, P. G.; *Oleum de cedro*, *Oleum limonum*.—*Essence de citron*, *Essence de limon*, Fr.; *Citronenöl*, *Limonenöl*, G.

The volatile oil extracted by mechanical means from the fresh peel of *Citrus Limonum*, *Risso*.

Nat. Ord.—Aurantiaceæ.

Preparation.—The fresh rind of nearly ripe lemons is pressed between the fingers in such a manner that the oil-cells are ruptured, the exuding oil being received upon a sponge, which when saturated is expressed; or the oil-cells are ruptured by a process of superficial grating, the oil being drained off. An oil of inferior fragrance is obtained by grating the outer rind completely off and distilling the magma with water. Oil of lemon is manufactured in Southern France and Italy. 34,227 pounds of oil of lemon and orange were imported in 1867 by the United States; in 1881 the importation of oil of lemon amounted to 111,375 pounds.

Properties.—Oil of lemon has a pale-yellow color, is limpid, neutral, of a very agreeable fragrance and mild, aromatic, bitterish taste. As received in commerce, it is usually turbid, but becomes clear on standing; by age it acquires a thicker consistence and a pungent terebinthinate odor and taste, which change is prevented or retarded by the addition of 5 per cent. of alcohol and decantation of the clear oil from the sediment; this treatment is now recommended by the Pharmacopœia for the preservation of the oil. Its specific gravity is about .852; it commences to boil at about $160^{\circ} C.$ ($320^{\circ} F.$), rotates polarized light to the right, produces a brisk fulmination with iodine, yields with Fröhde's reagent a deep orange-brown color (Dragendorff, 1876), and by hydrochloric acid gas is converted into a liquid and a solid compound, which, distilled over lime, yield again colorless oils, the former *citrylene*, the latter *citrene* (or *citronyl*), having a lemon-like odor. Oil of lemon yields with 7 parts of alcohol specific gravity .839 a turbid solution, but is soluble in all proportions in carbon disulphide or absolute alcohol.

Composition.—Aside from a small quantity of an oxygenated compound, oil of lemon consists of several hydrocarbons having the general formula $C_{10}H_{16}$. W. A. Tilden (1879) states that at least 70 per cent. of the oil consists of *citrene*, $C_{10}H_{16}$, boiling at $176^{\circ} C.$ ($348.8^{\circ} F.$), having an odor like hesperidene; 6 per cent. consists of *cymene*, $C_{10}H_{14}$,

and the remaining portion contains several hydrocarbons, an alcohol, $C_{10}H_{18}O$, boiling above $200^{\circ} C.$ and its acetic ether.

Adulterations with the volatile oils of other fruits of the genus *Citrus* are very difficult to detect; odor and taste must be chiefly relied on. "1 drop of the oil, triturated with sugar and agitated with 500 Gm. of water, should impart to the latter the pure odor of lemon."—*P. G.*

Off. Prep.—Linimentum potassii iodidi cum sapone, *Br.*; Spiritus ammoniæ aromaticus, *Spir. odoratus, U. S., Br.*

Medical Uses.—Oil of lemons is used almost exclusively as a flavoring agent and as a perfume.

OLEUM LINI, *U. S., Br., P. G.*—FLAXSEED OIL.

Linseed oil, E.; Huile de lin, Fr.; Leinöl, Leinsamenöl, G.

The fixed oil, expressed without heat, from the seed of *Linum usitatissimum*, *Linné.*

Nat. Ord.—Linaceæ.

Preparation.—This oil is made on the large scale by thoroughly drying the seed with the aid of heat, crushing, and forcibly expressing it. The yield by cold pressure is 16 to 20 per cent., by hot pressure 25 to 28 per cent. It is largely manufactured in this country; in 1867 over 3,200,000 gallons were imported into the United States, but the quantity decreased to 963 gallons in 1877, and was 12,169 gallons in 1883. The importation of flaxseed amounted in the years indicated to 1,769,192 bushels, nearly 85,000,000 pounds, and over 42,700,000 pounds respectively.

Properties.—Expressed in the cold, linseed oil is limpid, neutral to test-paper, yellowish or yellow, and of a peculiar bland not unpleasant odor and taste. For use in the arts linseed oil is obtained by hot pressure, is somewhat thicker, brownish, has more odor, and a somewhat acrid taste. Its specific gravity is about .936, but may vary between .928 and .953 (.936–.940, *P. G.*). It imparts a yellow color to alcohol on being agitated with it, dissolves in 40 parts of cold and 5 parts of boiling alcohol, in 5 parts of absolute alcohol, in 1.5 parts of ether, and in all proportions of oil of turpentine, chloroform, benzine, and carbon disulphide. At a low temperature it becomes thicker, and congeals at $-27^{\circ} C.$ ($-16.6^{\circ} F.$) to a yellowish mass. It yields with alkalis a very soft soap. In contact with fuming nitric acid it ignites, but when agitated with nitric acid of specific gravity 1.33 it turns green, and afterward brown; it does not solidify in contact with nitrous acid. Exposed to the air, it gradually thickens, becomes rancid, and finally solidifies; linseed oil thickened by exposure is incompletely soluble in alcohol. Crude oil which is mixed with mucilaginous matters quickly turns rancid and acquires an acid reaction; to obviate this change, the seed before expression is completely deprived of water. Linseed oil begins to boil at about $130^{\circ} C.$ ($266^{\circ} F.$), the boiling-point gradually rising, and when it has lost about 5 or 8 per cent. of its weight it constitutes *boiled linseed oil*, which is darker in color, thicker, and dries more rapidly than the unboiled oil.

Composition.—According to Mulder (1865), linseed oil is a mixture of about 80 per cent. of *linolein* with palmitin, myristin, and some olein, all being glycerides. *Linoleic acid* has the formula $C_{18}H_{32}O_2$, and is a colorless acid liquid readily soluble in alcohol and ether, and on exposure to air is converted into the hydrate of *oxylinoic acid*, which in its pure state is colorless and has the composition $C_{18}H_{26}O_3$, and on continued exposure, more rapidly if frequently moistened with ether, is transformed into *linoxyn*, $C_{32}H_{54}O_7$. This latter compound is insoluble in ether, and is produced in a few days on the exposure of boiled linseed oil. The acrid taste of linseed oil seems to be due to the presence of a little resin; according to others, to traces of volatile fatty acids.

Pharmaceutical Preparations.—OLEUM LINI SULFURATUM, s. Balsamum sulphuris. 6 parts of linseed oil are intimately mixed in an iron vessel with 1 part of sublimed sulphur, and the mixture boiled over a slow fire in an iron vessel, with constant stirring, until the whole has united into a homogeneous mass. It has about the consistence of a thick syrup, and is of a dark red-brown color. Diluted with three times its weight of oil of turpentine, it constitutes OLEUM TEREBINTHINÆ SULFURATUM, s. Balsamum sulphuris terebinthinatum.

Other Drying Oils.—The drying oils of walnut, hemp-, sunflower-, poppy-, and pumpkin-seeds are described elsewhere in connection with the drugs.

GRAPE-SEED OIL.—Huile de raisin, *Fr.*; Traubenkernöl, *G.*—The seeds of the different varieties of *Vitis vinifera*, *Linné* (nat. ord. Vitaceæ), yield from 10 to 20 per cent. of fixed oil, which is light-yellow or brownish, inodorous, faintly bitter, and congeals near $-16^{\circ} C.$ ($3.2^{\circ} F.$). It dries

very slowly, and consists, besides palmitin and stearin, chiefly of the glyceride of *erucic acid*, $C_{22}H_{42}O_2$; this acid melts at 34° C. (93.2° F.), and yields acetic and arachic acids on being fused with potassa.

MADIA OIL is obtained from *Madia sativa*, *Molina* (nat. ord. Compositæ, Tubulifloræ), an annual herb, native of Chili and cultivated in Europe, Africa, and Asia. The brownish-gray, quadrangular, four-ribbed akenes, which are destitute of pappus, yield about 40 per cent. of fixed oil. This is yellow, bland, of a peculiar odor, and has the spec. grav. .930, and congeals near -20° C. (-4° F.). On exposure to air it becomes rancid and slowly acquires a soft-solid consistence. By nitric acid it is colored brown-red, by sulphuric acid greenish and brown. Besides palmitin and stearin, it contains an olein, which seems to differ from that of other oils.

NIGER SEED OIL. *Guizotia oleifera*, *De Candolle*, s. *Verbesina sativa*, *Roxburgh* (nat. ord. Compositæ, Tubulifloræ), is indigenous to and cultivated in India and Eastern Africa. The subcylindrical, black, and glossy akenes yield about 40 per cent. of a thin yellow oil having a nutty flavor and congealing below -10° C. (14° F.). It is colored orange-yellow by nitric acid, and gray-green and brown by sulphuric acid, dries to a soft varnish, and consists of myristin, palmitin, and apparently two oleins, one of which is closely related to linolein.

CANDLE-NUT OIL, KEKUNE OIL, BANKUL OIL. The candle-nut-tree, *Aleurites triloba*, *Forster*, s. *A. moluccana*, *Willdenow*, is extensively cultivated in the islands of the Pacific and Indian Oceans and in India. The whitish kernels have a bland nutty flavor and yield about 60 per cent. of nearly colorless oil, which dries rapidly and is colored dark orange-red by nitric acid and yellow to brown by sulphuric acid. It consists of an olein resembling linolein, besides myristin, palmitin, and stearin.

Medical Uses.—Flaxseed oil is a laxative in the *dose* of 1 or 2 ounces (Gm. 32–64). It has been recommended to be given in this manner as a remedy for *hemorrhoids*. Only cold-pressed oil should be used internally. Its most important application is in the treatment of *burns* when mixed with an equal quantity of lime-water. The same mixture is also applied with advantage in *impetigo*.

OLEUM MENTHÆ PIPERITÆ, U. S., Br., P. G.—OIL OF PEPPERMINT.

Essence de menthe poivrée, Fr.; *Pfefferminzöl*, G.

The volatile oil distilled from *Mentha piperita*, *Linné* (see page 972).

Nat. Ord.—*Labiata*.

Preparation.—The fresh herb is distilled with water, or preferably with steam. For medicinal purposes the oil should be rectified by steam distillation. It is largely produced in Michigan, New York, and other States of the Union, and to some extent is exported to Europe, while, on the other hand, some European rectified oil of peppermint is imported into the United States. In Great Britain the yield is stated to be from 8 to 12 pounds of oil per acre (*Pharmacographia*); in the United States it is said to be sometimes as high as 20 pounds (Stearns, 1858).

Properties.—Oil of peppermint is a colorless, or more frequently yellowish or greenish-yellow, liquid, which on exposure becomes brownish and viscid. Its specific gravity is usually near .90, but varies between .84 and .94. It commences to boil near 190° C. (374° F.), and at a low temperature sometimes deposits crystals of menthol. It has a peculiar pungent odor and a warm, aromatic, somewhat camphoraceous, and when old also bitterish, taste, followed by a sensation of cold, which is most noticed on drawing air into the mouth. It dissolves clear in from 1 to 3 parts of 80 per cent. alcohol, the solution usually becoming opalescent with more alcohol, and depositing slowly a minute white precipitate. It is neutral to test-paper when fresh, and turns polarized light to the left. In its action toward reagents it shows very considerable differences. Some oils of peppermint yield with sodium bisulphite a solid compound which has not been further examined (Flückiger). Jehn (1873) observed that chloral hydrate produces with this oil a rose- and cherry-red color, and Dragendorff (1875) proved that this reaction is occasioned by some unknown constituent of impure chloral hydrate, and becomes less distinct the purer the reagent is. Strong nitric acid colors it purplish to brown, but when from 50 to 70 drops of the oil are mixed with 1 drop of nitric acid specific gravity 1.2, the mixture is gradually changed from yellowish to brownish, and finally to a permanent violet, blue, or greenish-blue when viewed in transmitted light, while in reflected light the mixture is of a red-copper color and opaque; the reaction, which is not prevented by oil of turpentine, may be hastened by warming the mixture or by decreasing the oil (Flückiger, 1871). Schack (1878–81) observed that an alcoholic solution of the oil and salicylic acid gradually becomes copper-green, and that the melted acid becomes at once blue-green on the addition of the oil; phenol and most

acids, but not carbonic acid, have a similar effect, and a mixture of 1 Ccm. of glacial acetic acid and 1 drop of oil of peppermint, slightly warmed, shows a blue color in transmitted light and a blood-red in reflected light; but menthol or oil of crisped mint does not yield the reaction. Pieric acid dissolves in oil of peppermint with a yellow color, gradually, or when slightly heated more rapidly, changing to green; in presence of water and air a reddish-yellow is afterward produced (Frebault, 1874). Iodine does not act energetically with the oil, but dissolves and renders it thicker. With ethereal or chloroformic solution of bromine a rose-red or violet color is produced, changing gradually to a dirty pink or purplish color. In consequence of insufficient weeding of the mint-fields, American oil of peppermint is not unfrequently mixed with oil of erigeron, acquires a rank "weedy" smell, and seems to be disposed to resinify more rapidly.

Composition.—Oil of peppermint owes its peculiar odor to *menthol* (mint camphor, mint stearopten), $C_{10}H_{20}O$, which is chiefly contained in the last portions obtained on subjecting the oil to fractional distillation. It forms colorless prisms which fuse at 42° C. (76° F.), and boil at 212° C. (414° F.). Distilled with phosphoric anhydride, it yields *menthene*, $C_{10}H_{18}$, which is a colorless liquid of an agreeable odor. According to Moriga (1881), oil of peppermint contains probably also an oil of the formula $C_{10}H_{18}O$, which may be prepared from menthol by oxidation with potassium bichromate; but by treatment with fuming nitric acid menthol yields at first an explosive oil, afterward crystals of an acid, $(C_5H_8O_4)_2H_2O$, melting at 97° C. (206.6° F.); this compound is not identical with pyrotartaric acid, with which it agrees in composition. A compound isomeric with borneol had been found by Beckett and Wright (1875) in the liquid portion of Japanese peppermint oil, but, according to Flückiger and Power (1880), is not present in the oil distilled at Mitcham, which contains, besides menthol, several hydrocarbons of the formulas $C_{10}H_{16}$ and $C_{15}H_{24}$, and having a terebinthinate somewhat lemon-like odor.

Adulterations.—Besides oil of erigeron, alcohol, castor oil, and oil of turpentine have been employed for the purpose; the presence of the last two bodies renders the oil not readily soluble in 80 per cent. alcohol, and the last one mentioned causes it to be acted on with more violence by iodine. Menthol is sometimes met with in commerce as *Japanese* or *Chinese oil of peppermint*, and is obtained from a plant which, according to Holmes, is nearly related to *Mentha canadensis*, *Linneé*. On one occasion it was largely adulterated with magnesium sulphate.

Off. Prep.—*Aqua menthæ piperitæ*, *U. S.*; *Essentia menthæ piper.*, *Br.*; *Pilul. rhei comp.*, *Spiritus menthæ piper.*, *U. S.*, *Br.*; *Trochisci menthæ piper.*, *U. S.*

Medical Action and Uses.—Elsewhere (see *MENTHA PIPERITA*) are described the carminative and anodyne virtues of peppermint, which belong to all its preparations, and especially to its essence (*Spiritus menthæ piperitæ*), which is merely an alcoholic solution of the oil. The latter appears to possess in a remarkable degree the analgesic properties of its class. Anciently, peppermint was employed by the Romans as an application to the temples for the relief of headache, and within a few years it became known that the oil (stearopten) was used by the Chinese for a similar purpose. In imitation of their practice, it has been a good deal employed as a local anodyne in *neuralgia* and *neuralgic headache*, applied over the supraorbital, the temporal, or other nerve in which the pain is most severe. A small wad of compressed cotton saturated with the oil should be laid upon the painful spot, covered with a piece of sheet caoutchouc, and bound firmly in its place. Merely painting the skin with the oil by means of a brush or a tuft of cotton will sometimes answer the purpose. In local *rheumatic* affections the latter method is often very efficient. It has also been used successfully as a topical anodyne in superficial *burns* and *scalds* and in *zoma*. According to Duncan, it is, like its homologue *thymol*, antiseptic (*Practitioner*, xxiii. 47). Lohber recommends the addition of the oil or the essence of peppermint to mixtures given internally in treatment of gonorrhœa. It is said to allay urethral pain (*Bull. de thérap.*, xcii. 105).

In *dental caries* this oil is quite as efficient in relieving pain as oil of cloves, and more permanent in its effects than chloroform. For internal use oil of peppermint may be prescribed in *doses* of from 1 to 3 drops (Gm. 0.05–0.15), but the official spirit is to be preferred.

OLEUM MENTHÆ VIRIDIS, *U. S.*, *Br.*—OIL OF SPEARMINT.

Essence de menthe verte, *Fr.*; *Römisch-Minzöl*, *G.*

The volatile oil distilled from *Mentha viridis*, *Linneé* (see p. 973).

Nat. Ord.—*Labiatae*.

Preparation.—The fresh herb is distilled in the United States and Great Britain with water or by means of steam; the yield is about $\frac{1}{4}$ to $\frac{1}{2}$ per cent.

Properties.—It resembles oil of peppermint in color, specific gravity, changes produced by exposure, and behavior to iodine and to polarized light, but differs from it in odor and the slight cooling taste. We have noticed that fresh oil of spearmint usually dissolves clear in all proportions, while old oil yields a turbid solution with more than 3 parts of 80 per cent. alcohol. Its boiling-point, according to Kane, is 160° C. (320° F.). Its odor, like that of oil of peppermint, is preserved for a long time by the addition of 3 or 4 per cent. of alcohol.

Composition.—Gladstone (1863) separated from the oil a hydrocarbon, $C_{10}H_{16}$, and an oxygenated oil, $C_{10}H_{11}O$, to which the odor is due, and which has the density .9515 and boils at 225° C. (437° F.).

Off. Prep.—*Aqua menthæ viridis*, U. S., Br.; *Spiritus menthæ viridis*, U. S.

Medical Uses.—Oil of spearmint is less used than the oils of peppermint and horsemint. It appears to be less powerful than those oils, and may be prescribed in doses of from 2 to 5 drops (Gm. 0.10–0.30), diluted with sweetened water or in the form of spirit of spearmint.

OLEUM MORRHUÆ, U. S., Br.—COD-LIVER OIL.

Oleum jecoris aselli, P. G.; *Oleum hepatis morrhue*.—*Cod oil*, E.; *Huile de morue*, *Huile de foie de morue*, Fr.; *Leberthran*, *Stockfischleberthran*, G.

The fixed oil obtained from the fresh liver of *Gadus Morrhua*, Linné, and of other species of *Gadus* (Class Pisces; Ord. Teleostia; Fam. Gadida).

Origin.—The common cod, formerly called *Asellus major*, inhabits the Northern Atlantic, and is frequently met with on the North American coast on and near the Banks of Newfoundland, where it seems the *lake*, *G. Merluccius*, Linné, s. *Merluccius communis*, Cuvier, pollack, *G. (Merlangus, Cuvier) pollachius*, Linné, and haddock, *G. aglfinus*, Linné, are likewise used to some extent for the same purpose. On the Norwegian coast, according to De Jongh (1843), cod-liver oil is mainly produced from the *dorse*, *G. Callarius*, Linné, but also from the pollack, the coal-fish, *G. (Merlangus, Cuvier) carbonarius*, Linné, the whiting, *Merlangus vulgaris*, Cuvier, s. *G. Merlangus*, Linné, and the ling, *Gadus (Lota, Cuvier) Molva*, Linné.

Preparation.—On the coast of Norway the carefully-cleaned livers are placed in baskets or barrels exposed in a sunny place, where the oil slowly exudes, and is removed and filtered; or the livers are slowly heated in a steam- or water-bath, or sometimes boiled with water, the oil being skimmed off from the surface. (See *Proc. Amer. Phar. Assoc.*, 1876, p. 810.) On the coast of North America cod-liver oil is now generally very carefully prepared. The introduction of ice as a means of preserving has developed the business of transporting codfish fresh to the inland cities during the catching season, from December to March, and likewise that of the proper preparation of cod-liver oil from fresh livers on shore by means of gradually applied steam-heat, whereby the oil is separated from the tissues, the watery portion subsiding: the oil is placed in butts in the cooling-room until it freezes solid, when it is put into canvas bags and expressed: the hard, yellowish residue, consisting of stearin and liver debris, is sold to soapmakers, while the clear oil is bottled or put into dry barrels. (See *Amer. Jour. Phar.*, 1854, p. 1; 1870, p. 214; 1883, p. 471; *Proc. Amer. Phar. Assoc.*, 1875, p. 659.)

Properties.—The purest cod-liver oil is of a pale-yellow color, never quite colorless unless artificially bleached: it is limpid, has a slight odor and taste, and a faint acid reaction: but if prepared at a high temperature, or if the livers are allowed to more or less putrefy, it has a more decided reaction and a pale or darker reddish-brown color, the darkest varieties being transparent only in thin layers, and having a repulsive fishy odor and a bitterish acid taste. The acidity and fishy smell are less marked in the light-brown oil, and still less in the yellow or white oil, which is nearly bland. At 15° C. (59° F.) the spec. grav. of light cod-liver oil is .920 to .925, of the dark-colored about .930. Cold alcohol dissolves not over 2.5 per cent. from the yellow, but about 6 per cent. from dark-brown, cod-liver oil; boiling alcohol dissolves 1 or 2 per cent. more. Ether, chloroform, and carbon disulphide dissolve it in all proportions: the oil is soluble in 2.5 parts of acetic ether. At a low temperature a granular crystalline deposit is separated, in largest proportion from the darker-colored oil, but good medicinal cod-liver oil should at 0° C. (32° F.) deposit very little or no stearin (P. G.). On the addition of sulphuric acid a violet color, soon changing to brown-red, is produced, due to the presence of biliary

compounds; the violet color is also produced on shaking a solution of 1 drop of cod-liver oil in 20 drops of carbon disulphide with 1 drop of sulphuric acid, but the color is very transient and becomes pale-red and brownish. Nitric acid colors cod-liver oil purple, afterward violet and brown. In contact with nitrous acid the oil becomes thicker, but does not solidify.

Composition.—Cod-liver oil has been repeatedly analyzed, and found to be a mixture of several glycerides, the principal one being olein, with variable quantities of stearin, palmitin, and myristin, increasing with the darker color. Hopfer de l'Orme (1837) first proved the presence of iodine, which, according to L. Gmelin (1840), was supposed to be in combination with potassium; however, hot and cold water and alcohol fail to extract it, and the precise form in which iodine is present is still unknown. The same may be said of bromine, phosphorus, and sulphur. Chevallier, Donovan, Herberger, Marder, and others did not find iodine in all samples of cod-liver oil; some investigators have found it in the ashes of soap prepared from it, others in the mother-liquor after separating the soap. De Jongh determined its amount to vary between .029 in dark and .040 per cent. in light-brown oil. Mitchell Bird (1882), however, ascertained that 10,000 parts of pale Norwegian oil contained only between .21 and .18 parts; pale Newfoundland oil, .12 parts; and the pale-brown oils, .16 and .14 parts of iodine. Winckler's (1852) statement that glycerin could not be obtained from cod-liver oil, which he regarded as an organic whole containing oxide of propyl, has not been corroborated by other investigators. P. Carles (1882) determined the amount of free acid, calculated as acetic acid, to be 0.01 and 1.80 per cent. in pale and brown cod-liver oils respectively. De Jongh regards the acid reaction of cod-liver oil as being due to butyric and acetic acids, and has recognized the presence in it of several biliary acids and coloring principles, besides *gaduin*, $C_{35}H_{46}O_9$, which is dissolved from the lead soap by ether, and separated with oleic acid by sulphuric acid. By combining with soda, dissolving in alcohol of 30° B., and cooling to the freezing-point of water, the soap is deposited, and gaduin may be obtained on the addition of sulphuric acid: it is dark-brown, brittle, inodorous, tasteless, soluble with a red color in sulphuric acid, and reprecipitated by water. It is probably a derivative of bile. *Gadic acid* is the name given by Luck (1857) to a deposit obtained from a light-brown cod-liver oil; recrystallized from hot alcohol, it fused between 63° and 64° C. (145.4° and 147.2° F.).

Adulterations are very difficult to detect, because the colors mentioned above are but slightly modified by the presence of other oils, and the oils obtained from the livers of some other fishes show similar reactions. Some fish oils, however, are but slightly colored by sulphuric acid; others do not become violet at first, but at once turn brown-red or dark-brown. Such substitutions may be detected by this test. An adulteration with resin, noticed by Böttger in 1858, may be detected by the solubility of the adulterant in alcohol. In other respects the physical properties, as detailed above, still afford the best criterion of the purity and quality of cod-liver oil.

Allied Oils.—OLEUM SQUALI.—Shark oil, *E.*; Huile de requin, de selache, *Fr.*; Haileberthran, *G.*—It is made from the liver of the shark, *Squalus Carcharias*, *Linne*, and one or two allied species, and is the lightest of the fish-oils, its density at 15° C. (59° F.) being .870 to .880. It is light-yellow, has an acrid taste, and remains limpid at -6° C. (21.2° F.).

OLEUM RAJE.—Ray oil, skate oil, *E.*; Huile de raie, *Fr.*; Rochenthran, *G.*—It is made from the liver of *Raja Batis*, *Linne*, and is employed in France and Belgium. The oil is pale- or bright-yellow, neutral, has the spec. grav. .928 at 15° C., a slight fishy odor and taste, and dissolves in 2 parts of ether. It is stated to contain more iodine than cod-liver oil. Oil is also extracted from the liver of the American *stingray*, *Pastinaca hastata*, *De Kay*.

Fish Oils.—These are in part obtained from different fishes, like the *Alosa Menhaden*, *Cuvier*, which is caught on the New England coast and yields *menhaden oil*, principally employed in leather-dressing. But among fish oils are also included the so-called *train oils*, obtained from the fleshy parts of different cetacean mammals; the principal ones are:

OLEUM CETI.—Sperm oil, *E.*; Huile de cachalot, *Fr.*; Pottfischthran, *G.*—From *Physeter macrocephalus*, *Linne*; it is yellow or brown-yellow, of spec. grav. .920, and in the cold deposits spermaceti and stearin (see also page 417).

OLEUM BALENE.—Whale oil, *E.*; Huile de baleine, *F.*; Walfischthran, *G.*—From *Balena mysticetus*, *Linne*, and *B. australis*, *Desmoulin*, the Greenland or right, and the cape or southern, whale. The oil has a peculiar fishy odor and unpleasant taste, a density of .926, and begins to deposit a sediment at about 10° C. (50° F.).

DUGONG OIL, from *Halicore Dugong*, *Cuvier*, which inhabits the waters of Eastern Australia and the Indian Archipelago, has been used in place of cod-liver oil in Australia.

Pharmaceutical Preparations.—OLEUM MORRHUÆ FERRATUM has been recommended for some years. Bernbeck (1875) published a process of which the following is an outline: A solution of 1 part of well-dried neutral olive oil soap in 20 parts of hot

water is precipitated by the gradual addition of a similar solution of 1 part of ferrous sulphate; the precipitated iron soap is rapidly collected on muslin, washed, and expressed to remove the water. This cake, though oxidizing superficially, will internally retain its whitish color for a long time. 4 parts of this soap are melted, and 96 parts of previously warmed cod-liver oil are added, and the heat continued for half an hour or more. This oil is of a dark-brown color, and contains 1 per cent. of metallic iron, mostly as ferrous oleate. A similar product is obtained by dissolving 1 or 1½ parts of ferric benzoate in 100 parts of cod-liver oil.

OLEUM MORRHUÆ IODATUM. Dissolve 1 part of iodine in a little ether, and add 1000 parts of cod-liver oil.

EXTRACT OF COD LIVER is the watery liquid obtained from the livers in preparing the oil, and evaporated; it yields 12½ to 15 per cent. of extract, which is said to consist of biliary constituents 60.6, water 21.8, the remainder being various salts. It was at one time (1866) recommended as a substitute for cod-liver oil.

Physiological Action.—When healthy animals eat cod-liver oil mixed with their ordinary food, it appears to promote their fattening if a moderate proportion is not exceeded. When more is given them, the digestion becomes deranged and their fat acquires a yellow color and a fishy taste. When the oil is rubbed into the shaven skin of dogs the animals appear to be in as good condition as if they had taken the oil internally, and the same evidences of its absorption are found in the bile and in the richness of the chyle in non-nucleated corpuscles. The experiments of Drs. Randolph and Rousset (*Phila. Med. Times*, xiv. 239) show that in 80 per cent. of infants treated by inunction of cod-liver oil a notable increase of fatty matters takes place in the stools. The fattening operation of the oil in man is familiar to every one; in connection with it the blood becomes richer in corpuscular elements, especially of red corpuscles, thereby, in certain cases, producing a morbid excess of nutritive action, which sometimes exhibits itself in hæmorrhage and sometimes in local congestions. When it is given in suitable doses and in appropriate cases it improves the appetite and digestion, but if taken in excess of the powers of assimilation, and too long continued, it impairs the appetite, renders the tongue foul, excites heartburn, rancid eructations, and even vomiting and diarrhœa, while itching of the skin and a papular eruption are produced, and the perspiration exhales a fishy smell.

Cod-liver oil is essentially a fat-producing agent, and thereby it retards the waste of nitrogenous tissues which is a characteristic of the diseases in which it is most serviceable. In this connection it should be borne in mind that among the various agents vaunted from time to time as remedies for consumption the most efficient have been oils and fats—*e. g.* asses' milk, cream, butter, fat pork, buffalo marrow, etc. But cod-liver oil has the advantage over all of these articles that it excels them in digestibility. On what the latter quality depends is not fully determined, but the most plausible opinion is that it is due to the portion of biliary matter which the oil holds in solution. It has been shown experimentally that different oils vary extremely in their diffusibility through membranes, and that cod-liver oil is six or eight times more diffusible than other oils, vegetable or animal. Such appears to be the simple fact, but the explanation of it is not easy. It has been ascribed to the presence in the oil of a certain proportion of bile, and it is asserted that when this bile is removed the oil loses its diffusibility in the same proportion. But, on the other hand, it is alleged that the process employed to remove the bile has not really that effect, but eliminates certain other constituents of the oil. However this may be, no more satisfactory theory has been proposed. Moreover, this view is corroborated by the experiment in which an animal with a biliary fistula became more and more emaciated as long as it used only its ordinary food, but regained flesh and strength when a due proportion of cod-liver oil was added.

Medical Uses.—From time immemorial cod-liver oil was used as a popular remedy for chronic gout and rheumatism, rickets, and scrofula in Great Britain and the countries bordering on the German Ocean, but it was not until about 1841 that it became generally known and used as a remedy for pulmonary consumption. The enthusiasm which inevitably attends the introduction of a new medicine of real efficacy exaggerated the benefits conferred by cod-liver oil in these several diseases, but time and well-considered experience have nevertheless proved it to be a valuable remedy. Its curative powers in *chronic rheumatism* have been strikingly shown in cases of that disease prolonged by a cachectic state of the system—cases in which the muscles grow rigid and the joints stiff, and when to the debilitating influence of these infirmities is added the influence of dampness, crowding, bad ventilation, and coarse and insufficient food, especially in persons of an originally scrofulous constitution. In regard to *scrofula* itself, the medicine is singu-

larly efficacious when the disease affects the internal lymphatic glands and the bones under the bad hygienic conditions just enumerated. Yet it is by no means to be depended upon in cases of supposed mesenteric disease—not only because the enlargement of the abdomen which is thought to indicate its existence in children is commonly a result of splenic or hepatic disorder, but, still more, because true *tuberculosis mesenterica* is most apt to be associated with incurable tuberculosis of the intestines. It is of little use in scrofulous enlargement of the parotid, thyroid, and submaxillary glands, or of the glands of the neck, axillæ, and groins; but its efficacy is seen in the cure of the ulcers left after the discharge of softened scrofulous matter from these parts. Its utility in *scrofulous ophthalmia* is far from being established; at least one-half of the cases receive no benefit from it. It is a more valuable remedy in all forms of idiopathic *strumous caries*, especially when it affects the epiphyses of the long bones; and it is still more evidently beneficial in *rachitis*. In the treatment of *white swelling* and other forms of *chronic arthritis*, and of *fistulæ* and *abscesses* in the neighborhood of joints, its powers are sometimes signally displayed. The various diseases of the skin to which scrofulous persons are peculiarly liable are often most favorably influenced by this medicine. Among them, *lupus vulgaris* is reputed to have been cured by it more frequently than by any other internal remedy, while some high authorities declare that no cure of existing *lupus* ever results directly from any kind of internal treatment whatever. It is true also that even when given for this disease it is generally associated with other and active medicines. In other scrofulous diseases of the skin, and especially of the scalp, this oil appears to have been used with success both internally and topically. Such diseases are *impetigo*, *chronic eczema*, *psoriasis*, and *favus*. Even *ichthyosis* is said to have been cured by similar means.

The great success which cod-liver oil at one time was believed to have gained as a cure for *pulmonary consumption* has tended more than any other cause to maintain the reputation of the medicine. It is now determined that it exerts little if any direct influence upon the structural elements of that disease, and that it can be said to cure only those rare cases in which other and especially hygienic methods have also restored consumptive patients to apparently good health. Such are the cases in which the patient is of a sluggish, lymphatic temperament, and in which the tubercular deposit is strictly limited to a small portion of one lung. The efficiency of the medicine is much more notable when a cavity is already formed than when the deposit is in a crude state. It plainly acts by maintaining the general health of the system while the local disease undergoes retrogression, for it constantly happens that although the latter process fails to occur, but on the contrary the destruction of the lung advances, yet the patient for a time gains weight and strength. In the more favorable examples the symptoms which depend upon the local lesion are mitigated, and even suspended, such as fever, sweating, cough, and expectoration. Yet in proportion as these symptoms prevail the oil fails to do good or is not tolerated. Although cod-liver oil is no longer claimed to be a cure for consumption, it still remains incomparably the most efficient medicine in prolonging the lives of the victims of this disease, and enabling them to take advantage of the hygienic measures upon which the main reliance must be placed. *Chronic bronchitis*, which is so apt to be mistaken for tubercular phthisis, is often signally benefited by this medicine and by the same mode of action. A like remark is applicable to numerous diseases of the *nervous system* due to or maintained by an exhausted condition of its functions.

In all diseases its use is contraindicated when it cannot be retained by the stomach or when it is not well digested, but causes eructation, heartburn, diarrhœa, etc., and generally when fever is present.

Administration.—The average *dose* of cod-liver oil is a tablespoonful (Gm. 15) three times a day an hour or two after meals. It is better to begin with half of this quantity. Various means have been employed to disguise the taste and smell of the oil and render it acceptable to the stomach. These means are generally superfluous among children, who often become fond of the medicine, and also among persons whose taste is not fastidious. The use of ether, naphtha, peppermint, and similar agents is objectionable, since they become volatilized in the stomach and renew the taste of the oil by eructation. Less apt to produce this effect is alcohol in the form of some distilled spirit, with which the mouth should first be washed, after which the oil, floating upon another portion of the liquor, may be rapidly swallowed. Malt liquor which froths readily is an excellent article for enveloping the oil and concealing its taste. Floated on iron-rust water, with some of which the mouth and fauces have just been washed, is another available means of effecting the same purpose. But the best of all is chewing a small fragment of smoked her-

ring. As acid condiments are eaten with fishy food, so it has been proposed to administer cod-liver oil with a modicum of walnut or tomato catsup. The various emulsions made for concealing the taste of the oil become more objectionable to most patients than the oil itself; they are also too bulky, by reason of the proportion of the excipient they require. When the stomach tends to reject the oil this effect can sometimes be prevented by preceding each dose by one of a solution of cyanide of potassium containing not more than $\frac{1}{2}$ grain (Gm. 0.008) of the cyanide. But the possible dangers of the misuse of this solution forbid its ordinary employment. It is better, as well as safer, to swallow a tablespoonful of lime-water or 5 or more grains (Gm. 0.30) of subnitrate or subcarbonate of bismuth a few minutes before the oil is taken. The oil has sometimes been mixed with arroroot or with spermaceti, forming a bolus which may be taken enclosed in a wafer.

"*Coluchan*" oil, derived from a small fish that is caught on the north-western coast of North America, is said to form an efficient substitute for cod-liver oil.

OLEUM MYRCIÆ, U. S.—OIL OF MYRCIA.

Oil of bay, E.; *Essence de myrcie (de bay)*, Fr.; *Myrcienöl*, Bayöl, G.

The volatile oil distilled from the leaves of *Myrcia acris*, *De Candolle*, s. *Myrtus* (*Eugenia*, *Wight et Arnott*, *Pimenta*, *Wight*, *Amomis*, *Berg*) *acris*, *Swartz*. *Bentley and Trimen, Med. Plants*, 110.

Nat. Ord.—Myrtaceæ.

Origin.—This medium-sized tree is known as *wild clove*, *wild cinnamon*, and *bayberry*, and is indigenous to the West Indies and Venezuela. The quadrangular branches bear opposite, shortly-petiolate, coriaceous, broadly oval, nearly obtuse, entire, strongly-veined, and pellucid-punctate leaves, which are about 3 inches (75 Mm.) long, and when bruised exhale an agreeable aromatic odor, somewhat similar to cloves. The flowers are small, reddish, and stalked; the fruit is a globular-ovoid smooth berry, resembling allspice. Much of the oil and the spirit (bay rum), particularly the latter, are now distilled in the United States, about 200 pounds of the oil being annually imported.

Preparation.—The leaves are distilled with water or by the aid of steam; at first a light oil, floating upon water, comes over, afterward an oil heavier than water; the light and heavy fractions, united, constitute the commercial oil. The yield is very variable (*Markoe*, 1877).

Properties.—Oil of myrcia recently distilled is of a light-brownish color, but becomes darker on exposure. It has an aromatic odor, resembling that of cloves and allspice, but more fragrant, and a warm, pleasantly spicy taste. Its specific gravity is about 1.040. It dissolves in alcohol in all proportions, the solution having a slight acid reaction. Strong potassa solution converts it into a crystalline mass of potassium eugenate. Sulphuric acid produces a red, afterward brown, color; iodine dissolves quietly in the oil; strong nitric acid causes a violent reaction.

Composition.—Prof. *Markoe* (1877) showed the oil to be a mixture of a hydrocarbon having at 15.5° C. (60° F.) the specific gravity .8356, and of eugenol, spec. grav. 1.055. L. C. *Pettit* (1880) obtained 41 per cent. of eugenol, which gave a crimson-red color with sulphuric acid. (For accounts of this volatile oil see *Amer. Jour. Phar.*, 1861, p. 297, and *Proceedings of Amer. Phar. Assoc.*, 1877, p. 435.)

Off. Prep.—*Spiritus myrciæ*, U. S.

Uses.—This oil is chiefly used as a perfume, and especially as an ingredient of bay rum (*Spiritus myrciæ*).

OLEUM MYRISTICÆ, U. S., Br.—OIL OF NUTMEG.

Oleum nucistæ æthereum.—*Volatile oil of nutmeg*, E.; *Essence de muscade*, Fr.; *Ätherisches Muskatöl*, G.

The volatile oil distilled from the seed of *Myristica fragrans*, *Houttuy*n.

Nat. Ord.—Myristicaceæ.

Preparation.—Ground nutmegs are distilled by the aid of steam. The yield is between 2 and 3 per cent., but selected nutmegs yield sometimes as much as 8 per cent. *Cloëz* (1864) suggested exhaustion with carbon bisulphide and distilling the extract by means of steam.

Properties.—The oil is colorless or pale-yellowish, limpid, of specific gravity .92 to .95, of an agreeable aromatic odor, a warm somewhat camphoraceous taste, and dextrogyre to polarized light. It is readily soluble in alcohol, commences to boil at 160° C.

(320° F.), fulminates when brought into contact with iodine, is energetically acted on by nitric acid, becomes dark-red with Fröhde's reagent, and violet by hydrochloric acid (Dragendorff, 1877).

Composition.—The most volatile portion, after treatment with sodium, was found by Cloëz to be a left-rotating hydrocarbon, $C_{10}H_{16}$, having the odor of nutmeg and of lemon, and boiling at 165° C. (329° F.). It is the *myristicene* of Gladstone (1872), who named the oxygenated portion *myristicol*, $C_{10}H_{14}O$; this is dextrogyre, boils at 224° C. (435° F.), and does not, like menthol and carvol, yield a crystalline compound with H_2S . The *nutmeg camphor* of John (1821) or *myristicin* of Gmelin, which separates sometimes on standing, was ascertained by Flückiger (1874) to be myristic acid. (See below.)

Off. Prep.—Pil. aloes Socotr., Spirit. ammon. aromat., Br.; Spir. myristicæ, U. S., Br.

Medical Uses.—Oil of nutmeg is seldom used in medicine; it may be employed for the same purposes as nutmeg in doses of 2 or 3 drops (Gm. 0.10–0.15).

OLEUM MYRISTICÆ EXPRESSUM, Br.—EXPRESSED OIL OF NUTMEG.

Oleum nucistæ, P. G.; *Adeps (Butyrum) myristicæ*, s. *nucistæ*.—*Nutmeg butter*, E.; *Beurre de muscade*, Fr.; *Muskatnussöl*, *Muskatbutter*, G.

Preparation.—This fixed oil is obtained in the East Indies by beating nutmegs into a paste, which is expressed between heated plates. The yield is about 28 per cent., and the annual importation into the United States is usually between 300 and 500 pounds; in 1880 it was 1964 pounds. The oil is incorrectly called *oil of mace*.

Properties.—It is found in commerce in the shape of blocks about 2½ inches (6 Cm.) thick and 10 inches (25 Cm.) long, and is wrapped in palm-leaves. It is solid and firm, unctuous to the touch, of a mottled appearance, orange-brown and whitish in color, of specific gravity .995, and has the fragrance and aromatic but bland taste of nutmegs. It melts at about 45° C. (113° F.), and is soluble in 2 parts of warm ether and 4 parts of boiling strong alcohol (Lecanu).

Constituents.—Cold alcohol dissolves about 6 per cent. of volatile oil (see above) and 24 per cent. of fat, accompanied by brown-yellow resinous matter, which has not been further examined. The remaining pulverulent white fat is *myristin*, $C_3H_5(C_{14}H_{27}O_2)_3$, which crystallizes from hot alcohol or ether and fuses at 31° C. (87.8° F.). Heintz (1854) found the melting-point of *myristic acid* at 53.8° C. (128.8° F.). Schmidt and Rømer (1883) found 3 to 4 per cent. of free myristic acid, with a little stearic acid.

Adulterations.—Artificial mixtures made from animal fats are not soluble in the same amount of hot alcohol, and the portion insoluble in cold alcohol would be more or less greasy. "On warming 1 part of nutmeg butter with 10 parts of alcohol a solution should be obtained which, after cooling and filtering, is clear and pale-yellow, and with the addition of ammonia should become brownish, but not red (turmeric); ferric chloride should color the solution merely dingy-brown."—P. G.

CERATUM MYRISTICÆ, s. BALSAMUM NUCISTÆ, P. G. Melt together yellow wax 1 part, olive oil 2 parts, and expressed oil of nutmeg 6 parts; pour into paper capsules and cut into square cakes.

Off. Prep.—Emplast. calefaciens, Empl. picis, Br.

Allied Fats.—BECUBA TALLOW is expressed from the seeds of *Myristica Beccuhyba*, Schott, s. M. officinalis, *Martius*, which is indigenous to Brazil. The fat resembles the official article, but has a sharp acidulous taste, melts at 47° C. (116.6° F.), and on treatment with cold absolute alcohol leaves 45 per cent. of yellow pulverulent residue undissolved.

OTOBA BUTTER is prepared from *Myristica Otoba*, Humboldt et Bonpland, indigenous to North-western South America. It is yellowish, becomes brown by age, melts at 38° C. (100.4° F.), and has then an unpleasant odor. Its myristin melts at 46° C. (114.8° F.), and contains *otobit*, which is sparingly soluble in cold alcohol, crystallizes in colorless, inodorous, and tasteless prisms, and melts at 133° C. (271.4° F.) (Uricoechea, 1854).

VIOLA TALLOW, OCUBA WAX, is prepared from *Viola* (*Myristica*, Swartz) *sebifera*, Aublet, indigenous to Guiana. The fat is yellowish, somewhat crystalline, completely soluble in alcohol, and melts at 45° to 50° C. (113°–122° F.).

Medical Uses.—Oil of nutmeg is sometimes used for the friction of *rheumatic* parts, but chiefly as a bland and smooth fatty substance that does not easily grow rancid, and is therefore suitable as an excipient of more active topical medicines.

OLEUM OLIVÆ, U. S., Br.—OLIVE OIL.

Oleum olivarum, P. G.—Sweet oil, E.; *Huile d'olive*, Fr.; *Olivenöl*, G.

The fixed oil expressed from the fruit of *Olea europæa*, *Linneé*. Woodville, *Med. Bot.*, t. 98; Bentley and Trimen, *Med. Plants*, 172.

Nat. Ord.—Oleaceæ.

Origin.—In its wild state the olive is almost shrubby, much-branched, and thorny, but under cultivation it is a medium-sized tree 30 or 40 feet (9–12 M.) high. It is indigenous to Western Asia, particularly Syria, and has been cultivated for a long time in the countries bordering on the Mediterranean. It has been introduced into the Southern United States, California, and several South American and other countries. The tree has evergreen, opposite, shortly-petiolate leaves, which are about 2 inches (5 Cm.) long, lanceolate, acute at both ends, entire and revolute on the margin, and densely scaly, silvery gray, brownish- or glaucous-green beneath. The numerous small white flowers are in axillary racemes, diandrous, have a two-celled and four-ovuled superior embryo, and produce a purplish-black ovate drupe about an inch (25 Mm.) long, with a greenish, firm sarcocarp and an obliquely oblong keeled putamen containing a single albuminous seed.

The leaves and bark have been employed in France as a febrifuge. De Luca (1861, etc.) found the leaves and green fruit to contain mannit, which diminishes in the latter as the

fruit ripens, and disappears entirely when it becomes perfectly ripe. It contains then the largest amount of oil, equal in weight to nearly 70 per cent. of the sarcocarp.

Preparation.—The finest quality of olive oil is obtained by crushing the recently-collected ripe olives in a suitable mill to a pulpy mass, care being taken in some districts not to break the putamen containing the seed; the pulpy mass is then subjected to moderate pressure, the oil, called *virgin oil* (*Huile vierge*, Fr.; *Jungfernöl*, G.), being collected in cisterns containing water, from the surface of which it is subsequently skimmed. The press-cakes are afterward thoroughly mixed with water and the marc again expressed, using an increased pressure, whereby a second quality of oil is obtained; in some places cold water is first used for softening the press-cakes, and is followed by hot water. However, with the improvements in the construction of powerful presses this portion of the process is much simplified, and a larger yield of oil of fine quality is obtained. The oil still remaining in the marc is said to amount to between 9 and 12 per cent., and is extracted by means of carbon disulphide; or the marc is thrown into cisterns, which in Southern France are called *enfer*, and where an oil called *huile d'enfer*, having a disagreeable odor, separates upon the water. A larger amount of oil, but much inferior in quality, is yielded by expressing olives which have been kept in heaps and undergone a kind of fermentation:

Olea europæa, *Linneé*.

this oil is known in France as *huile fermentée*; and a still more inferior oil is prepared by again mixing the residue with boiling water and expressing. Though the seeds have a bitterish taste, Flückiger found the oil to be quite bland, to be a non-drying oil, and, if extracted with the oil of the fruit, to constitute about one-fortieth of the latter.

Olive oil enters commerce put up in bottles of various sizes, also in stone jugs and in barrels. The importation of olive oil into the United States amounts annually to over 400,000 gallons, fully three-fifths of which quantity is *salad oil*.

Properties.—Olive oil is a pale-yellow or greenish-yellow oily liquid, having a neutral reaction, a slight agreeable odor, and a bland taste, leaving, even in its freshest condition, a slight sense of acidity (*Pharmacographia*), which is somewhat increased on keeping. Its specific gravity at 15° C. (59° F.) is 0.9178, or between 0.915 and 0.918 (U. S. P. G.). At and below 10° C. (50° F.) olive oil separates white crystalline granules; near 2° C. (35.6° F.) it is of a butyraceous consistence; and it congeals completely at or below the freezing-point of water, yielding, however, by strong pressure, from 67 to 72 per cent. of liquid oil, which remains fluid at –10° C. (14° F.), and is nearly pure *olein*. The solid portion fuses between 20° C. (68° F.) (Pelouze and Boudet) and 28° C. (82.4° F.) (Locanu), and is easily soluble in ether. Olive oil is sparingly

soluble in alcohol, freely soluble in ether, soluble in all proportions in chloroform, benzol, benzin. and carbon disulphide, and in about 5 parts of acetic ether. It does not readily become rancid, and belongs to the non-drying oils. When heated to 120° C. (248° F.) it becomes lighter, and at 220° C. (428° F.) nearly colorless, and at the same time rancid; it commences to boil at about 315° C. (600° F.).

Inferior qualities of olive oil are of a deeper hue, become cloudy, and congeal more easily, have a more decidedly acrid after-taste, and turn rancid on exposure.

The German Pharmacopœia recognizes two qualities of olive oil—the one intended for internal use and for ointments, the other used for the preparation of plasters:

OLEUM OLIVARUM, s. OLEUM PROVINCIALE.—Best olive oil, *E.*; Huile d'olive fine, *Fr.*; Provencèröl, *G.*—It is the oil described above.

OLEUM OLIVARUM COMMUNE.—Olive oil, *E.*; Huile d'olive ordinaire, *Fr.*; Baumöl, *G.*—This is the second quality of salad oil, has a brownish-yellow or green-yellow color, and, except a somewhat less pleasant odor and taste, agrees with the preceding.

Composition.—The liquid portion is *triolein* (olein), $C_3H_5(C_{18}H_{33}O_2)_3$, and is identical with the liquid portion of most non-drying fats, as far as they have been examined. The solid part was called *margarin* by Chevreul, which was proven by Heintz (1852) to be a mixture containing chiefly *palmitin*. Palmitic acid, $C_{16}H_{32}O_2$, was obtained from olive oil by Collett (1854), and also by Heintz and Krug (1857), who likewise isolated *arachic* (*butiric*) acid, $C_{20}H_{40}O_2$, and probably stearic acid. On saponification glycerin is obtained. The fats composing olive oil are, therefore, triolein, tripalmitin, triarachin, and possibly tristearin. Beneke (1862) announced also the presence of a small quantity of *cholesterin*, $C_{26}H_{44}O$, which is soluble in alcohol (see page 670).

Adulterations.—Olive oil is frequently adulterated with other bland oils, some of which are occasionally even substituted for it. The determination of its purity has been the subject of much research, but from the chemical identity of the constituent compounds of many oils, and the natural variation of their relative proportions in the same fat, it is evidently attended with many difficulties. A higher specific gravity than given above points to an admixture of other fats. The detection of drying in non-drying oils, and the testing by means of sulphuric acid, etc., have been described above.

Tests.—The Pharmacopœia gives the following: "If 1 part of olive oil be agitated in a test-tube with 2 parts of a cold mixture prepared from equal volumes of strong sulphuric acid and of nitric acid of sp. gr. 1.185, and the mixture be set aside for half an hour, the supernatant oily layer should not have a darker tint than yellowish (a dark color indicating the presence of other fixed oils)."—*U. S.* Olive oil remains pale-yellow or becomes greenish; benne oil turns reddish or red; sunflower oil, orange-yellow; ground-nut oil, reddish-brown; cotton-seed oil, dark-red. "If 1 Gm. of the oil be shaken for a few seconds with 1 Gm. of a cold mixture of sulphuric acid (sp. gr. 1.830) and nitric acid (sp. gr. 1.250) and 1 Gm. of disulphide of carbon, no green or red layer should separate on standing."—*U. S.* Foreign oils give the tints mentioned above. "If 12 parts of the oil be shaken frequently, during 2 hours, with 1 part of a freshly-prepared solution of 6 Gm. of mercury in 7.5 Gm. of nitric acid (sp. gr. 1.420), a perfectly solid mass of a pale straw-color should result."—*U. S.* "If 15 parts of olive oil be well shaken with 2 parts of water and 3 parts of fuming nitric (nitroso-nitric) acid, the mixture should be whitish, not red or brown (oils of ground-nut, benne-seed, and cotton-seed), and in one or two hours should separate into a slightly-colored liquid and a white solid mass."—*P. G.* The elaidin test is conveniently applied in the manner described under OLEA PINGUA, where also the result with different oils is stated and the colors produced by sulphuric acid and other reagents. "If 5 drops of the oil are let fall upon a thin layer of sulphuric acid in a flat-bottomed capsule, no brown-red or dark-brown zone should be developed within 3 minutes at the line of contact of the two liquids (absence of appreciable quantities of other fixed oils of similar physical properties)."—*U. S.* "If 5 drops of the oil be well agitated with 15 drops of nitric acid spec. grav. 1.38, neither the acid nor the oily mass should acquire a red color (oils of benne, cotton-seed, etc.)."—*P. G.*

According to Cailletet (1877), the greenish color is occasionally produced by the presence of copper, in which case the oil will be colored brown on being agitated with an ethereal solution of pyrogallie acid.

Pharmaceutical Uses.—OLEUM CHLORINATUM, *Chlorinated oil*, is prepared by Dr. L. Wolff by passing chlorine gas into olive oil; it is a yellowish oil, and has been used in itch and other cutaneous diseases. According to Lefort (1852, 1853), olive oil, thus treated, contains chlorine substitution-products, the *chloroleic acid* having the

formula $C_{18}Cl_2H_{32}O_2$, a brown color, the specific gravity 1.082, and containing 20.6 per cent. of chlorine.

OLEA COCTA, OLEA INFUSA.—Oleoinfusions, *Oleols. E.*; Oléolés, Elæolés, Huiles médicinales, *Fr.*; Gekochte Oele, *G.*—These preparations were formerly much employed in Europe, and several of them have retained a place in the French Codex. They are made from herbs or flowers, either aromatic or narcotic, by digesting 1 part of the dry drug in 10 parts of olive oil, or by boiling 1 part of fresh narcotic herb in 2 parts of olive oil until the moisture has been dissipated. Ointment of stramonium was formerly prepared in a similar manner.

Off. Prep.—Cataplasma lini, *Br.*; Ceratum camphoræ, Cerat. cetacei, *U. S.*; Charta cantharidis (epispastica), Empl. plumbi, *U. S., Br.*; Enema magnes. sulphat., *Br.*; Unguentum diachylon, *U. S.*; and several plasters, liniments, and ointments, *Br.*

Medical Action and Uses.—From time immemorial olive oil formed an important article of food in countries where the olive tree flourishes, and was used as butter is elsewhere. In the *dose* of 1 or 2 ounces it acts as a very mild laxative, but it is seldom administered for this purpose except to infants, for whom a sufficient dose is a teaspoonful. It has been used as an antidote to the poisonous effects of *cantharides*, and is probably efficient by protecting the stomach, as well as by occasioning vomiting, notwithstanding the theoretical objection that cantharidin is soluble in sweet oil. It has been extensively and efficiently employed by workmen in white-lead factories to keep the bowels free and prevent the absorption of the metal. A notion has been entertained that large doses of olive oil were capable of causing the discharge of *gall-stones*, and in proof of the statement a great number of bodies resembling these concretions has been found in the stools. On examination, however, they were found to consist of the partially saponified oil (*Boston Med. and Surg. Jour.*, Sept. 1881, p. 261). It is used in some places in Europe to prevent the poisonous effects of *vipers' bites*, both internally and locally, and by the latter method it is familiarly applied to allay the swelling and pain of *insects' bites and stings*. It is often poured into the *auditory canal* to destroy insects concealed therein, and large doses of it have been known to kill and expel a *tenia*. Externally, it is a convenient and efficient protective and lenitive for superficial *wounds, excoriations, burns, bruises, and sprains*. In the two last-mentioned injuries it should be applied warm, and in them also it affords a convenient vehicle for the application of camphor, morphine, and various other anodynes or stimulants. The same is true in regard to several local inflammations, especially *ear-ache*. With lime-water it forms the liniment so useful in burns (*Linimentum calcis*). Anciently, the custom of anointing the body with oil was practised, as it still is in Oriental countries, after warm bathing, and also as a protective against the plague. It is now occasionally used to moderate excessive *sweating*. Warm oil is a soothing and efficient application, when made with appropriate pressure or friction, in lessening the pain and swelling of enlarged glands, particularly when they are actively engorged, as the *mammæ* during pregnancy and after parturition. It is sometimes injected into the rectum in *dysentery* and to destroy rectal *ascarides* (oxyures), and it is habitually employed to facilitate the introduction of *sounds, catheters, bougies, specula, pessaries*, etc. into the natural cavities of the body. It was an old custom to dip cutting surgical instruments in oil before incising the flesh.

The *dose* of olive oil as a laxative is 1 or 2 fluidounces (Gm. 32–64) for adults, and for infants 1 or 2 fluidrachms (Gm. 4–8).

OLEUM PALMÆ.—PALM OIL.

Huile (Beurre) de palme, Fr.; *Palmöl, Palmbutter, G.*

From the fruit of *Elæis guineensis*, *Jacquin*.

Nat. Ord.—*Palmæ*.

Origin.—The oil-palm is a tall tree indigenous to Western Africa and introduced into other tropical countries. It has large pinnate leaves with spiny petioles and long narrow linear leaflets. The fruit is a yellow mottled drupe about an inch (25 Mm.) long, and contains a leathery very oily sarcocarp, from which the fat is obtained by pressure or by boiling with water. The kernel yields likewise a bland oil which is white and melts at 25° C. (77° F.). Nearly 917,000 gallons of palm oil were imported into this country in the year 1876–77, and nearly 1,250,000 gallons in 1882.

Properties.—Palm oil is solid at low temperatures, butyraceous, of a reddish-yellow color, and when fresh of an agreeable violet-like odor, and fuses at 27° C. (80.6° F.). On keeping, it becomes lighter in color and acquires a rancid odor, a portion of the fat

being decomposed into free acids and glycerin, the fusing-point rising at the same time, sometimes to 42° C. (107.6° F.). When rapidly heated to 240° C. (464° F.) it is bleached. It is partly soluble in alcohol, but entirely so in ether. Its specific gravity is .945.

Composition.—It consists chiefly of tripalmitin and triolein, and contains a peculiar ferment, inducing its decomposition. It is largely used in the preparation of soap; and to obtain the latter white, the oil is bleached by treating it with a solution of potassium bichromate and adding sufficient sulphuric and hydrochloric acids to form potassium sulphate and chromic chloride.

Other Palm Oils.—(See also OLEUM COCOS.) *MACAJA BITTER*, obtained from the seeds of *Cocos aculeata*, *Jacquin*, of tropical America, has a yellowish color and a violet-like odor.

TUCUM OIL, from the fruit of *Astrocaryum vulgare*, *Martius*, of South America, has a bright-red color and an agreeable odor.

Medical Action and Uses.—Palm oil has hardly any peculiar virtues to distinguish it from other vegetable fats, except that it is less drying and more emollient. It is supposed to be especially adapted for bathing *bruises* and *sprains*. Its agreeable odor recommends it.

OLEUM PHOSPHORATUM, U. S., Br., F. Cod.—PHOSPHORATED OIL.

Huile phosphorée, Linniment phosphoré, Fr.; Phosphorhaltiges Oel, G.

Preparation.—Phosphorus 1 part (9 grains); Stronger Ether 9 parts (81 grains or 2 fluidrachms); Expressed Oil of Almond a sufficient quantity; to make 100 parts (900 grains). Introduce a sufficient quantity (about 3 fluidounces) of expressed oil of almond into a flask, heat it on a sand-bath to 250° C. (482° F.), and keep it at that temperature for 15 minutes. Then allow it to cool, and filter it. Put 90 parts (810 grains or 15½ fluidrachms) of the filtered oil, together with the phosphorus, previously well dried by blotting-paper, into a dry bottle capable of holding somewhat more than 100 parts; insert the stopper, and heat the bottle in a water-bath until the phosphorus melts; agitate it until the phosphorus is dissolved, allow it to cool, and add the ether. Lastly, transfer the solution to small glass-stoppered vials, which should be completely filled and kept in a cool and dark place.—*U. S.*

The process of the British Pharmacopœia differs from this in heating the almond oil only to 149° C. (300° F.), and in directing 16 grains of phosphorus to be dissolved in 4 fluidounces (Imperial) of the oil at a temperature of about 82° C. (180° F.). The U. S. P. has adopted Méhu's process (1868), who, however, directs heating the oil for 15 minutes to 150° C. (302° F.), and then to raise the heat for 10 minutes to 250° C. At first, air and moisture are given off; afterward certain organic matters are volatilized or destroyed: the oil becomes nearly colorless, and on cooling separates a little flocculent matter, which is separated by filtration. A piece of translucent phosphorus is then weighed out, well dried, and dissolved as directed. The French Codex directs phosphorus 1 Gm., almond oil 95 Gm., ether 4 Gm. The oil contains 1 per cent. (*U. S., F. Cod.*), (.99 per cent. *Br.*) of phosphorus, the solubility of which in fixed oils is generally stated to be 1 in 100. According to Dr. Squibb (1876), phosphorus should be dissolved in oil only in an atmosphere of carbonic acid gas, and at once transferred into small dry and well-stopped bottles; he recommends to thus prepare a solution of well-dried phosphorus 1 part in cod-liver oil 99 parts.

Properties. Phosphorated oil is a clear yellowish oil having the odor of phosphorus and of ether, the presence of which prevents phosphorescence in the dark. The phosphorated oil of the British Pharmacopœia is strongly phosphorescent, and produces white vapors in contact with air, due to the oxidation of phosphorus.

Medical Action and Uses.—In so far as phosphorus is useful as a medicine it may be conveniently administered in this oil, which contains 3 grains of phosphorus in each fluidounce, and may be prescribed in the *dose* of from 5 to 10 minims (Gm. 0.30–0.60). It is very convenient as an addition to cod-liver oil in cases of *scrophula*, *chronic phthisis*, *paralysis* without central lesion of substance, *sexual debility*, and diseases referred to under PHOSPHORUS.

OLEUM PICIS LIQUIDÆ, U. S.—OIL OF TAR.

Huile (Essence) de goudron, Fr.; Theeröl, Pechöl, G.

A volatile oily liquid distilled from wood-tar.

Preparation.—Wood-tar is subjected to distillation, and that fraction of the distil-

late which is lighter than water collected by itself. (See CREASOTUM, p. 513. and PIX LIQUIDA.)

Properties.—Oil of tar, recently distilled, is colorless, but gradually darkens, becoming yellowish, brownish, and dark red-brown, and depositing a black product. The oil has a strong tar-like odor and taste, an acid reaction, and a density of about .970; these properties are, however, subject to variation from differences in the composition of the tar.

Composition.—The oil is a mixture of various hydrocarbons, of acetic and other acids, and of undetermined empyreumatic products present in tar; prepared from tar of coniferous woods, the oil consists largely of oil of turpentine.

Action and Uses.—This preparation has the same action as tar itself, and, like it, is used largely in the treatment of squamous and some other diseases of the skin. In Europe the oil of cade, obtained from *Juniperus oxycedrus*, is held in higher esteem than oil of common tar. Oil of tar may be applied directly to the affected part, more or less diluted with some bland oil, or in an ointment. It has the advantage over tar ointments of being less unsightly and less destructive to clothing.

OLEUM PIMENTÆ, U. S., Br.—OIL OF PIMENTO.

Essence de piment de la Jamaïque, Fr.; *Pimentöl*, *Nelkenpfefferöl*, G.

The volatile oil distilled from the fruit of *Eugenia Pimenta*, *De Candolle* (nat. ord. Myrtaceæ).

Preparation.—Allspice is ground, and then distilled with water or by means of steam, the volatile oil coming over usually in two fractions—a lighter and a heavier one, which are mixed. The average yield appears to be about 4 per cent., but is often much lower. Bonastre (1827) states that the seeds contain 5 per cent. and the remaining part of the fruit 10 per cent. of volatile oil.

Properties.—Oil of pimento is colorless or pale-yellow, becoming darker and thicker by age. Gladstone (1872) gives its specific gravity as 1.0374 at 10° C. (50° F.). In taste and in behavior to solvents and chemicals, (alcohol, test-paper, ferric chloride, potassa, iodine, etc.) it closely resembles oil of cloves; its odor, however, is more pleasant.

Composition.—Gladstone has corroborated the observation of Bonastre concerning the presence of *eugenic acid* and the close similarity of this oil to oil of cloves. L. C. Pettit (1880) obtained 61 per cent. of *eugenol*, which became red, and afterward purple, with sulphuric acid.

Medical Uses.—The oil of pimento is used for the same purposes, local and general, as other aromatic stimulants. The dose is from 2 to 6 drops (Gm. 0.10–0.30).

OLEUM RICINI, U. S., Br.—CASTOR OIL.

Oleum Palmæ Christi.—*Huile de ricin*, Fr.; *Ricinusöl*, G.

The fixed oil expressed from the seeds of *Ricinus communis*, *Linné*. *Bot. Mag.*, plate 2209; Bentley and Trimen, *Med. Plants*, 237.

Nat. Ord.—Euphorbiaceæ.

Origin.—The castor-oil plant appears to be indigenous to Southern Asia, but was early introduced into all tropical and subtropical countries, in many of which it has become naturalized, attaining in the tropics the size of a tree 30 to 40 feet (9–12 M.) high. It is often cultivated in temperate countries for ornament and other purposes, remaining an annual, varying in size from 4 to 14 feet (1.2–4.2 M.). Numerous varieties are now known, differing from one another in size and color of the stem and foliage, as well as of the fruit and seeds. The leaves are alternate, peltate, palmately seven- or nine-lobed; the inflorescence is paniculately spicate, terminal, finally axillary; the flowers are monœcious, apetalous, the staminate ones at the base of the panicle. The fruit is a subglobular, somewhat triangular, and grooved tricocous capsule, which is sometimes nearly smooth, but mostly spinescent; each cell encloses a single oval or elliptic seed, which is from $\frac{1}{8}$ to $\frac{2}{8}$ inch (8–16 Mm.) long, $\frac{1}{8}$ to $\frac{1}{4}$ inch (4–8 Mm.) broad, flattened on one side, smooth, shining, of a gray color variegated with yellowish, brown, or reddish spots and lines, with a slightly-raised raphe along the flattish side and a prominent caruncle near one end; this, when detached, leaves a slight depression above the hilum. The testa is hard, but brittle; the inner seed-coat is thin, white, and has a brownish chalaza; the embryo is straight, white, has broad, foliaceous heart-shaped cotyledons, and is imbedded in an oily albumen having a bland and scarcely acrid taste.

Preparation.—Nearly all the castor oil which is at the present time consumed in the United States is manufactured from seeds grown in the country or imported. While in the year ending June 30, 1867, the importation of castor oil was 82,800 gallons and of the seeds 60,588 bushels, the quantities imported in 1882 were 904 gallons and 2,389,200 pounds respectively. The seeds, after having been crushed and freed from the integuments, or without removing the latter, are kiln-dried and subjected to powerful pressure; the oil thus obtained is heated with water to remove albuminous matters, and when clear drawn off into barrels or other suitable vessels. The yield is stated to be

FIG. 199.

Ricinis communis, Linné: fruit, seed, and two longitudinal sections of seeds, showing embryo and albumen; natural size.

between 38 and 45 per cent., by cold pressure 25 to 30 per cent. More oil, but of inferior quality, is obtained by again expressing the marc and using a higher temperature and greater power; the additional yield is 6 to 8 per cent. The older method of obtaining the oil by boiling the seeds with water and skimming it from the surface has probably been abandoned in most countries. L. Boerner (1876) extracted from the press-cake with ether 14 per cent. of oil having a light-yellow color, while alcohol dissolved 21 per cent. of dark oily matter.

Purification.—Cold-pressed castor oil is nearly transparent, and requires no further purification. If opaque, the oil is filtered, either through paper or felt, or, as recommended by Pavesi (1857), is previously treated for several days with 1 per cent. of magnesia and 2.5 per cent. of purified animal charcoal; which treatment renders it nearly colorless and inodorous.

Properties.—Castor oil is viscid, transparent or nearly so, almost colorless or pale greenish-yellow, of a faint, mild, mawkish, but not repulsive odor, and a bland, afterward slightly acrid, taste. Its specific gravity varies between .950 and .960. At a low temperature it becomes thicker, and usually deposits white granules of solid fat; near -18° C. (0° F.) it congeals to a yellowish mass. It is only partly soluble in petroleum benzine, but is soluble in all proportions in absolute alcohol, ether, and glacial acetic acid, and at 15° C. (59° F.) in about 4 parts of alcohol spec. grav. 0.835. The oil has a neutral reaction to test-paper, but when exposed to the atmosphere in thin layers it becomes rancid, has an acid reaction, and slowly dries to a transparent varnish. In contact with nitrous acid, however, castor oil becomes much thicker, and finally congeals, requiring for this a longer time than the non-drying oils. Polarized light is by some samples turned to the right, by others to the left. It commences to boil at about 265° C. (509° F.), yields an oily distillate containing *œnanthol*, $C_7H_{14}O$, and *œnanthyllic acid*, $C_7H_{14}O_2$, and leaves a black mass which is soluble in potassa. Castor oil, agitated with equal weights of water and nitric acid, yields a whitish mixture, turning yellow in the presence of nitrous acid; but when heated with dilute nitric acid or with potassium bichromate and sulphuric acid, *œnanthyllic acid* is obtained. The oil is very readily saponified by alkalis.

Composition.—1. THE OIL. Castor oil is composed of several fats, the acids of which have been the subject of repeated investigations. The solid, fatty acid is probably identical with, or closely related to, *palmitic acid*; the liquid one has been named *ricinic* or *ricinoleic acid*, $C_{18}H_{34}O_2$, and forms a colorless or wine-yellow, inodorous liquid, of a disagreeable acrid taste, solidifying below 0° C. (32° F.) to a granular mass, and under the influence of nitrous acid is converted into *ricinelaiddic acid*, which has the same composition and crystallizes in silky needles. These acids differ from oleic acid in containing one more atom of oxygen, but they do not, like the latter, yield sebacic acid among their products of destructive distillation. *œnanthol* or *œnanth-aldehyd* is a thin, colorless, strongly refractive liquid, having an agreeable odor and boiling at 154° C. (309.2° F.). *œnanthyllic* or *œnanthic acid* is oily, of a codfish-like odor, and, dissolved in strong alcohol and treated with hydrochloric acid gas, yields *œnanthic ether*, $C_2H_5.C_7H_{13}O_2$, which has

a pleasant fruity odor, a specific gravity of 0.873, boils at 188° C. (370.4° F.), and is one of the constituents of wine. The acrid principle of castor oil has not been isolated.

2. THE SEEDS. Besides the oil, of which the seeds contain about one-half their weight, a considerable amount of protein compounds, some sugar, and mucilage are met with in them. Among the proteids is one which H. Bower (1854) regards as related to *emulsin*, inasmuch as it generates, with amygdalin, the odor of hydrocyanic acid. This observation was confirmed by Boerner (1876). The proteid is obtained by agitating the emulsion of the seeds with ether and precipitating the aqueous liquid with alcohol.

In 1864, Tuson announced the discovery of an alkaloid, *ricinine*, which is isolated by preparing an extract with boiling water, freeing it from the fat, exhausting with alcohol, filtering when cool, and crystallizing by concentrating the liquid. It is described as crystallizing in rectangular prisms and scales, possessing a slight bitter-almond taste, being sublimable, and containing nitrogen. Boerner (1876) found it necessary to treat the alcoholic liquid with magnesia; the crystals obtained by him resembled in behavior those of Tuson, but did not react with the usual reagents for alkaloids. Wayne (1874) isolated apparently the same principle from the leaves, and opposed its claim to be considered an alkaloid. Werner (1870) regarded it as a magnesium salt.

The seeds, freed from oil by pressure, are violently purgative, but the principle to which this action is due has not been isolated. On mixing the marc with water and allowing the mixture to ferment, Boerner obtained butyric and probably other volatile acids, but no acetic acid. These results were confirmed by Raab (1879). Flückiger obtained 10.7 per cent. of ash from the testa, but only 3.5 per cent. from the exsiccated kernel of the seed.

Off. Prep.—Collodium flexile, *U. S., Br.*; Liniment. sinapis comp., Pilul. hydrarg. subchloridi comp., *Br.*

Allied Oil.—TAMBOUR OIL, of Central America, has purgative effects, but does not gripe like castor oil. Hemsley (1882) ascertained it to be prepared from the seeds of *Omphalea oleifera*, *Hemsley* (nat. ord. Euphorbiaceae).

Physiological Action.—Castor oil derives its purgative properties chiefly from an acrid principle contained in castor beans, which, when taken designedly or accidentally, have repeatedly occasioned violent pain, vomiting, purging, collapse, and even death, after which evidences of severe inflammation have been found in the mucous membrane of the stomach and intestines. An acrid principle exists also in the leaves of the plant. When castor oil was injected into a vein its taste was presently perceived in the mouth, and there followed nausea, eructation, rigidity of the muscles of the tongue, loss of speech, anxiety, and faintness, with general dulness and depression. At the end of 3 hours an unsuccessful motion to evacuate the bowels occurred, followed by feverishness and an indisposition of several weeks' duration. Given to nursing mothers, it invariably purges their infants. Rubbed upon the skin of the abdomen in young children, it has procured one or two loose stools. Taken in medicinal doses, it sometimes nauseates, seldom gripes, but is apt to cause a tendency to sleep. The first evacuations which follow are generally liquid, and contain more or less of the oil, either unchanged or converted into cheesy flakes or a soap-like scum floating on the surface of the dejection. It has long been observed that when used as an habitual laxative the dose may be progressively diminished. Indeed, unless this is done it is very apt to occasion constipation and all its attendant evils. In a case of hydræmia with venous pulsation castor oil, given by the mouth, did not purge, but exuded through the skin.

Medical Uses.—Castor oil is used as a purgative whenever the intention is simply to overcome constipation, or, on the other hand, to cure *diarrhæa* depending upon the presence of irritating substances in the bowel, or upon congestion, irritation, and excessive secretion produced by cold. In not a few cases, especially of infantile diarrhæa, the intestine is irritated at once by the presence of undigested food and by the vitiated secretions of its lining membrane: the patients are distressed by colic, tenesmus, and frequent stools, which are watery, mucous, and bloody in different proportions; the mouth is aphons and the anus inflamed. In such cases the first step should be thoroughly to cleanse the intestine by means of castor oil in small and repeated doses, preceded or not by a small dose of calomel or of mercury with chalk. The rest of the treatment may be confided to medicines of a different kind and to dietetic regimen. This purgative has the advantage over most others of analogous qualities that it has no tendency to exhaust the strength. Hence it is much used during *pregnancy*, and especially immediately before *labor*. There is a popular notion that it tends to relax the maternal organs. Castor oil has been highly

recommended in *colica pictorum*, or Poitou colic, produced by acid drinks containing lead, and in *colica pictorum*, or painter's colic, caused by the habitual absorption of the metal. In the former affection it affords prompt relief; in the latter it has no superiority over other, and especially saline, cathartics. It sometimes suffices to expel *lumbricoid worms*, but cannot be at all depended upon for the removal of *tæniæ* unless they are previously killed by a proper tæniacide. In the forming stage of *laryngeal or bronchial inflammation* a laxative dose of castor oil is far superior to any other evacuant in promoting the bronchial secretion and thereby tending to hasten the cure. It is usually given after parturition when *milk fever* threatens, and later when signs of *mammary abscess* arise. It is also commonly prescribed after wounds and surgical operations to mitigate *traumatic fever*; it is said to palliate the pain caused by *renal calculi*. The local uses of castor oil were mainly suggested by the custom among African aborigines and their American descendants of applying castor-leaves to the mamæ to excite the flow of *milk*. They produce a slight irritation of the skin. A fluid extract prepared from the leaves and applied in the same manner is said to have a like effect, and a decoction has been used for the cure of *amenorrhœa*. Elsewhere abundant illustrations of this statement may be found (STILLE, *Therapeutics*, 4th ed. ii. 504), and more recently (1880) Boucher and Fonssagrives have claimed the re-establishment of the secretion of milk by bathing the breasts with a decoction of the leaves, after which a poultice made of the same leaves was applied to the nipples (*Philæ. Med. Times*, x. 415). The oil enters into numerous liniments, etc. for the cure of *alopecia*. Of these one of the best is composed of suet 3ij; castor oil 5vj; gallic acid 5ss. Mix, and scent with essence of vanilla. Castor oil is often prescribed in emulsion with yolk of egg, mucilage, etc., but its activity is thereby diminished. Its taste may be disguised by giving with it an equal quantity of glycerin to which a few drops of oil of cinnamon have been added. It should not be taken in milk, coffee, hot soup, or any other articles of food, lest they become repugnant afterward. If the mouth and fauces are washed with an alcoholic liquid, or even with glycerin, the oil will not adhere, and therefore will not excite disgust; or it may be floated upon fresh orange-juice in a wineglass, and covered with another layer of the juice, and so tossed down the throat without its taste being perceived. Probably the best expedient of all is to envelop the oil with the froth of beer, ale, or porter in a wineglass; it may then be swallowed without even its presence being detected. The average *dose* of castor oil for an adult is from $\frac{1}{2}$ ounce to an ounce (Gm. 16-32), taken at once or in separate portions according to the nature of the case. The *dose* for an infant is about a fluidrachm (Gm. 4). For an enema 1 or 2 fluidounces (Gm. 32-64) may be given in $\frac{1}{2}$ pint of mucilage or soap and water.

OIL OF ANDA ASSU, a product of Brazil, closely resembles castor oil in its operation. The seeds are said to have been used from a remote period as a purgative; the oil acts thoroughly and gently in doses of from 2 to 3 drachms, but in larger quantities is apt to purge harshly and profusely. A griping principle is said to reside in the embryo and the skin of the seed, both of which should be removed in preparing an emulsion of the seeds. The oil has not the nauseous taste of castor oil, and does not adhere so closely to the palate (*Edinb. Med. Jour.*, xxvii. 556, 646).

OLEUM ROSÆ, U. S., P. G.—OIL OF ROSE.

Oleum rosarum.—Attar (Otto) of rose, E.; *Essence de rose*, Fr.; *Rosenöl*, G.

The volatile oil distilled from the fresh flowers of *Rosa damascena*, Miller.

Nat. Ord.—Rosaceæ, Roseæ.

Origin and Production.—Roses are largely cultivated in India and various parts of Northern Africa for the production of rose-water and attar, which, however, are consumed in those countries. Large quantities of rose-water are distilled in Southern France, but little oil is obtained there. Commerce is almost exclusively supplied with oil of rose from the southern slope of the Balkan Mountains in Roumelia, the principal dépôt being the town of Kizanlik. The species of rose cultivated in that district, according to Baur (1867), is a variety of *Rosa damascena*, Miller, which grows to the height of over 6 feet (1.8 M.) and is raised in hedge-like rows. The flowers appear in May and June, and are collected before sunrise for distillation on the same day. The still used is made of copper, conical in shape, and has its globular head connected with a straight tin tube passing through a tub filled with water. The charge for each still is about 10 okes (or 27 pounds) of flowers and 20 okes of river-water, and the distillation is completed in 2 hours. The distillate is again distilled, the first sixth being set aside to allow the oil to

separate, while the remainder, together with the water pressed from the exhausted flowers, is used for fresh roses in place of water. The average annual production of oil of rose is about 4000 pounds, of which quantity over 10,000 ounces are imported into the United States; in the year ending June 30, 1882, the importation amounted to 21,933 ounces.

Properties.—Oil of rose is pale-yellow, transparent, solidifies if slowly cooled above 10° C. (50° F.) to a perfectly transparent mass composed of scale-like crystals, which on rapid cooling are narrow, feathery, resembling prisms, and fuse again at a somewhat higher temperature (at 12° – 15° C. = 53.6° – 59° F., *P. G.*). The congealing- and fusing-points vary to some extent; the former is given by Baur at between 11° and 16° C. (51.8° and 60.8° F.); the latter, by Hanbury (1859), as lying between 16.1° and 18.3° C. (61° and 65° F.), and for English oil of rose was found as high as 32.8° C. (91° F.). Zeller observed the fusing-point of German oil of rose to be even 37.5° C. (99.5° F.). Oil of rose has a neutral reaction to test-paper, but Zeller found it to have an acid reaction (see *Adulterations* and *Tests* below); its specific gravity may vary between about .84 (.87, *Pharmacographia*) and .89. The odorous portion is quite freely soluble in alcohol, while the inodorous stearopten is sparingly soluble in this liquid; absolute alcohol yields with the oil a clear solution (Baur). The oil has the odor of the flowers in a high degree, and when suitably diluted with alcohol is very fragrant. Its taste is sweetish and rather mild.

Composition.—When oil of rose is mixed with about 3 parts of alcohol, and the undissolved portion repeatedly dissolved in a little ether and reprecipitated by alcohol, it is finally obtained as transparent, iridescent, inodorous scales, which, according to Saussure (1820), Blanchet (1833), and Flückiger (1868), have the formula $C_{16}H_{22}$, fuse at 35° C. (95° F.), and distil above 280° C. (536° F.) (Blanchet). Flückiger gives the melting-point at 32.5° C. (90.5° F.) and the boiling-point at 272° C. (521.6° F.). This stearopten requires about 500 parts of alcohol for solution (Saussure), and is present in Turkish oil of rose to the amount of 6 or 7 per cent. (Hanbury), but in much greater proportion in oil obtained from roses grown in other parts of Europe. The elaeopten of oil of rose contains oxygen, but its exact composition has not been ascertained: it remains liquid at -15° C. (5° F.) (Baur, 1872), and, according to Gladstone (1872), has the density .881 and boils at 216° C. (420.8° F.).

Adulterations.—The oil which is mostly employed for adulterating oil of rose is known in commerce as *Turkish oil of geranium*, and was shown by Hanbury (1859) to be entirely different from the volatile oil of pelargonium. It is obtained in India from *Andropogon Schœnanthus*, *Linne*, known as *roshe* or *rosé oil*, in Turkey as *idris yaghi* or as *entershak*, and in English commerce also as *oil of ginger-grass*; it is imported into Turkey for the purpose of adulterating oil of rose, but, according to Baur, first subjected to a refining process, which consists in agitating the oil with lemon-juice and water, and in bleaching it by exposure to the sun and air, whereby a little copper is removed, the color changed from brownish to pale-yellowish, and the originally harsh and sharp odor rendered mild; or the oil is, in Roumelia, sometimes distilled with rose-petals. The adulterations used outside of Turkey are *oil of rhodium*, distilled from the root of *Convolvulus* (*Rhodorrhiza*, *Webb*) *Scoparius* and *floridus*, *Linne*, which grow in the Canary Islands; and *oil of rose-geranium*, or French oil of geranium, distilled from the cultivated *rose-geranium*, *Pelargonium roseum*, *Willdenow*. These oils have an acid reaction; oil of rhodium also a bitter taste and an odor resembling that of a mixture of rose, cubeb, and copaiba.

Tests.—The most certain criteria of the purity of the oil of rose are, according to Baur—1, the odor, by which oil of rose-wood, sandal-wood, and others may be detected; 2, the temperature at which it congeals; and 3, the manner of crystallizing. Pure oil of rose exposed to a temperature of 12.5° C. (54.5° F.) should congeal in a few minutes; the crystals should be transparent, scaly, iridescent, and float in the liquid, while spermaceti, being heavier, is deposited as a solid opaque crust. "If a solution of 1 part of oil of rose in 5 parts of chloroform be diluted with 20 parts of alcohol, the mixture should separate crystalline scales and should not redden moist litmus-paper. 1 drop of oil of rose triturated with sugar and afterward agitated with 500 Gm. of water, should impart to the latter the pure odor of rose."—*P. G.*

Medical Uses.—It is used in medicine exclusively for perfuming ointments and lotions.

OLEUM ROSMARINI, *U. S., Br.*—OIL OF ROSEMARY.

Oleum anthos.—*Essence de romarin*, Fr. ; *Rosmarinöl*, G.

The volatile oil distilled from *Rosmarinus officinalis*, *Linné*.

Nat. Ord.—*Labiatae*.

Preparation.—This volatile oil is obtained from the flowering-tops, or more frequently from the entire plant, by distilling them with water or steam. Commerce is chiefly supplied with oil of rosemary from Southern France and Italy. About 20,000 pounds of it are annually imported.

Properties.—Oil of rosemary is a colorless or yellowish limpid liquid, varying in specific gravity between 0.88 and 0.91, has a pungent somewhat camphoraceous odor and taste, boils at 165° C. (329° F.), and is soluble in less than its own weight of 80 per cent. alcohol; old oil requires a larger quantity for solution. Mixed with iodine, it gives off reddish vapors, and strong sulphuric and nitric acid render it thick and brown-red. Fröhde's reagent colors it yellowish-brown. The oil deviates polarized light to the left.

Composition.—The presence of oxygen in oil of rosemary was proven by Saussure (1820). Gladstone (1863) regarded it as consisting almost entirely of a hydrocarbon very similar to that contained in the oil of *Myrtus communis*, *Linné*. Lallemand (1859), however, obtained by fractional distillation a hydrocarbon boiling at 165° C. (329° F.) and a liquid boiling at 200° C. (392° F.), from which a stearopten was obtained having the composition and most of the properties of camphor; treatment with diluted nitric acid increases the yield of camphor. Bruylants (1879) obtained about 8 per cent. of camphor, $C_{10}H_{16}O$, melting at 176° C. (348.8° F.), and about 5 per cent. of borneol, $C_{10}H_{18}O$; the hydrocarbon, $C_{10}H_{16}$, boils near 160° C. (320° F.).

Pharmaceutical Preparations.—*UNGUENTUM ROSMARINI COMPOSITUM*, *s. UNG. NERVINUM*, *P. G.* Melt together lard 16, suet 8, yellow wax 2, and expressed oil of nutmeg 2 parts, and while cooling add oil of rosemary and oil of juniper-berries each 1 part.—*P. G.* *Baume nerval* of the French Codex is a similar preparation.

Off. Prep.—*Linim. saponis*, *Tinctura lavandulæ comp.*, *U. S., Br.*; *Spiritus odoratus*, *U. S.*; *Spiritus rosmarini*, *Br.*

Medical Action and Uses.—This oil is poisonous to rabbits in the dose of 20 grains. A case is recorded in which, along with oil of wormwood, it caused the death of a child. Internally, it may be employed for the same purposes as other stimulant oils to relieve *colic*, promote *menstruation*, and allay *nervous disorder* due to debility. In ointments and liniments it is a useful ingredient for relieving *rheumatic* pains; it promotes the removal of swellings due to *rheumatism*, *sprains*, *bruises*, etc., and stimulates the growth of the hair in *alopecia* following febrile affections. Its vapor cautiously allowed to act on the conjunctiva sometimes improves *vision* impaired by nervous exhaustion. Internally, the dose is 1 or 2 drops (Gm. 0.05–0.10).

OLEUM RUTÆ, *U. S., Br.*—OIL OF RUE.

Essence de rue, Fr. ; *Rautenöl*, G.

The volatile oil distilled from *Ruta graveolens*, *Linné*.

Nat. Ord.—*Rutaceæ*.

Preparation.—This volatile oil is distilled with water or steam from the fresh and cut herb. Lewis obtained from the fresh flowering herb .82 per cent., and after the fruit had matured 2.6 per cent., of volatile oil; Zeller's yield was from dry herb about $\frac{1}{4}$ per cent., from fresh herb $\frac{1}{20}$, and from the seeds 1 per cent.

Properties.—Oil of rue is a colorless or greenish-yellow liquid having the peculiar odor of the plant, a pungent somewhat acrid and bitterish taste, a neutral reaction, and congealing at a low temperature in shining scales. The freezing-point varies in different samples—according to Geiss (1861), between -2.5° and -22.5° C. (27.5° and -8.5° F.), that from the seeds congealing first. The specific gravity varies between .86 and .91. The oil is soluble in an equal weight of alcohol. Iodine dissolves quietly in the oil; sulphuric acid dissolves it with a brown-red color; and sodium bisulphite yields with it a crystalline compound. By the action of nitric acid *caprinic*, *pelargonic*, *caprylic*, and *ænanthyllic acids* are produced, the products varying with the strength of the acid and its prolonged action.

Composition.—Aside from a small quantity of a hydrocarbon, $C_{10}H_{16}$, boiling below 200° C. (390° F.), oil of rue consists mainly of an oxygenated portion, which Cahours and Gerhardt (1845) stated to be *caprinic aldehyd*, $C_{11}H_{22}O$. Harbordt (1862) showed

that it could not be an aldehyd, and regarded it as *methyl-caprinol*, $C_{10}H_{19}.CH_3.O$, and Strecker as a ketone having the formula $CH_3.CO.C_9H_{19}$. The latter view has been proven to be correct by the simultaneous observations made by Gorup-Besanez, F. Grimm, and A. Giesecke (1870). This *methyl-nonyl ketone*, when pure, is a colorless liquid with a bluish fluorescence, boiling at $225^{\circ} C.$ ($437^{\circ} F.$), crystallizing in scales near $5^{\circ} C.$ ($41^{\circ} F.$), and fusing again at $15^{\circ} C.$ ($59^{\circ} F.$).

Medical Action and Uses.—An experimenter, having taken within an hour three doses of oil of rue of 10 minims each, suffered uneasiness in the stomach, oppression and confusion of mind, aching in the loins, an urgent desire to urinate—the urine smelling of the oil—flushes of heat, unsteadiness of gait, a tendency to sleep, and increased frequency, with diminished tension, of the pulse. These phenomena are essentially those produced by oil of wormwood and numerous other essential oils, and the therapeutic uses of oil of rue are the same as theirs—viz. in the treatment of *colic*, *amenorrhœa*, *dysmenorrhœa*, *uterine hæmorrhage*, and *verminous complaints*. It may be given in doses of from 1 to 5 drops (Gm. 0.05–0.30).

OLEUM SABINÆ, U. S., Br.—OIL OF SAVIN (SAVINE).

Essence de sabine, Fr.; *Sadebaumöl*, G.

The volatile oil distilled from *Juniperus Sabina*, Linné.

Nat. Ord.—Coniferæ.

Preparation.—Oil of savin is obtained by distilling the fresh branches with water or steam. The yield is between $1\frac{1}{2}$ and $2\frac{1}{2}$ per cent.; Voget obtained from the berries nearly 10 per cent. of volatile oil. About 500 pounds of this oil are annually imported.

Properties.—The crude oil has a yellowish or yellow color, and is obtained colorless on rectification. It has the peculiar terebinthinate odor of savin, a pungent, camphoraceous, and bitterish taste, and when fresh a neutral reaction; on exposure to air it becomes thicker, reddish or brown. It dissolves in absolute alcohol in all proportions, but yields an opalescent solution with 3 parts of 80 per cent. alcohol. Dragendorff (1876) found the fresh oil at $28^{\circ} C.$ ($82.4^{\circ} F.$) to dissolve in 0.9 parts, and after rectification in 3.7 parts, of 85 per cent. alcohol. Its specific gravity is about 0.91, but varies somewhat. It commences to boil near $160^{\circ} C.$ ($320^{\circ} F.$), but the greater part of the oil boils above $200^{\circ} C.$ ($390^{\circ} F.$). Mixed with powdered iodine, a brisk detonation results, and on the addition to the oil of an ethereal solution of bromine the color of the latter disappears instantly. The oil does not appear to yield a solid compound with hydrochloric acid gas. It rotates polarized light to the right.

Composition.—Dumas (1835) found it to agree with oil of turpentine in elementary composition. But W. A. Tilden (1877) showed the lower-boiling portion to have the composition $C_{10}H_{16}O$, while the remaining portion does not contain a terpene, but consists of hydrocarbons, which are easily polymerized by heat.

Medical Uses.—Oil of savin is an appropriate medicine in all of the cases to which savin itself is applied; that is to say, in *amenorrhœa* depending upon a torpid condition of the organs of generation, and in *dysmenorrhœa* occurring under similar conditions. Its repute as a remedy for *sterility* arises from its stimulant influence upon those organs, and the same is true of its power to control passive *uterine hæmorrhage* and *leucorrhœa*, especially of uterine origin. In all of the cases its efficacy depends upon its power of stimulation. Locally, oil of savin has been applied to benumb the sensibility of exposed nerves in *dental caries* and to promote the shrivelling of *condylomata*.

The *dose* of this oil is from 2 to 10 drops (Gm. 0.10–0.60). It may be given in emulsion, pill, or alcoholic solution.

OLEUM SANTALI, U. S., Br.—OIL OF SANTAL.

Oleum ligni santali.—Oil of sandal-wood. E.; *Essence de santal*, Fr.; *Santelöl*, *Sandelöl*, G.

The volatile oil distilled from the wood of *Santalum album*, Linné (nat. ord. Santalaceæ).

Origin.—The white santal is a small tree indigenous to Southern India and some of the East Indian islands, and cultivated in other parts of tropical Asia. *Santalum Yasi*, Seemann, of the Fiji Islands, *S. Freycinetianum*, Gaudin, and *S. pyrularium*, A. Gray, of the Sandwich Islands, and several other species, yield likewise sandal-wood.

The leaves of white sandal are opposite, and vary in shape between oval and lanceolate,

and are smooth and glaucous beneath. The flowers are small, numerous, in paniculate cymes, very variable in color, and without odor. In India the trees are felled or dug up when the trunk is about a foot (30 Cm.) in diameter, the branches are cut off, and the trunk is left on the ground until the sap-wood has been mostly eaten away by ants, when it is trimmed, the heart-wood alone being used. *Santalum lanceolatum*, *S. obtusifolium*, *S. ovatum*, and other Australian species yield a wood of inferior odor.

SANTALUM ALBUM, LIGNUM SANTALI ALBUM, S. CITRINUM.—Santal-wood, Yellow (White) sanders-wood, *E.*; Bois de santal citrin, *Fr.*; Gelbes (Weisses) Santelholz, Sandelholz, *G.*—Santal-wood is in billets varying in thickness from about 3 to 8 or 9 inches (7–22 Cm.) and in color from whitish to brownish-yellow, the deeper-colored being more highly valued than the paler varieties. The wood is hard and heavy; when cut transversely it has a somewhat waxy lustre and irregular concentric zones alternately lighter and darker in color, sometimes rather indistinct, with very fine vessels and delicate medullary rays. When rubbed or rasped it has an agreeable aromatic somewhat roseate odor; its taste is aromatic, bitterish, and slightly acid. Odor and taste, however, vary much with the origin of the wood.

Preparation.—The wood is distilled with water or steam, and yields from 2 to 5 per cent. of oil; in India, with imperfect stills, 2.5 per cent. is obtained (*Pharmacographia*). Dr. Bidie states that the roots yield the largest amount and finest quality of oil. Between 2500 and 3000 pounds of the oil are imported into the United States.

Properties.—Oil of santal is a thick, light-yellow liquid having in a high degree the aromatic odor of the wood from which it has been distilled, and a pungently aromatic taste; its reaction is neutral or slightly acid, and its behavior to polarized light either left- or right-rotating. Its density is usually about .96, and it is said to be occasionally heavier than water; Chapoteaut (1882) obtained from East Indian wood 1.25 to 2.8 per cent. of oil of the specific gravity .945. The oil begins to boil at 214° C. (417° F.), the boiling-point quickly rising to 255° C. (492° F.) (*Pharmacographia*). Chapoteaut's oil boiled between 300° and 340° C. (572° and 644° F.). Dragendorff (1876) found oil of santal distilled from different varieties of wood to be soluble in all proportions of 91 per cent. alcohol, but East Indian oil yielded with 11 parts of 80 per cent. alcohol an opalescent solution, while the solutions of other varieties of oil were clear with 1.2 to 1.8 parts of the same alcohol. Old oil seems to be less soluble than that which has been recently distilled.

Constituents.—The physical differences pointed out indicate that oils prepared from different woods vary in their composition, but they appear to be oxygenated oils. Chapoteaut (1882) isolated two fractions, $C_{15}H_{24}O$, boiling near 300° C. (572° F.), and $C_{15}H_{26}O$, boiling at 310° C. (590° F.). Distilled with phosphoric anhydride, they yield the hydrocarbons $C_{15}H_{22}$ and $C_{15}H_{24}$, of which the former resembles the hydrocarbon of oil of cedar-wood, and the latter seems to be identical with oil of copaiba.

Santal-wood contains also a resinous principle, and a tannin which is colored green by ferric salts.

Adulterations.—Oil of santal is said to be adulterated with oil of copaiba and oil of cedar-wood; the former is sparingly soluble in alcohol sp. gr. .85. For detecting the latter Durand (1878) recommends agitating 1 Gm. of the oil with 1 Gm. of concentrated cuprammonium solution and 4 Gm. of water; after 24 hours' rest pure oil of santal gives a white opaque soap, while that with oil of cedar-wood is greenish.

Medical Action and Uses.—About 1865 oil of sandal-wood was introduced as a substitute for copaiba in the treatment of *gonorrhœa*. In some cases it was found to produce nausea or disturbance of the stomach, and the odor it communicated to the urine was described as sickening. Its smell upon the hands and breath was also said to be extremely persistent. But the more frequent statement was that it had a far less disagreeable smell than copaiba, and was generally preferred to it. In some cases it agreed with patients who could not tolerate copaiba. The general result, however, appears to be that while it possesses no decided superiority over that medicine, it is fully equal to it in efficiency. Like copaiba, it must be given for some time after the urethral discharge has ceased. Like that medicine also, it is very serviceable in chronic *diarrhœa*, especially of the mucous variety, and in chronic bronchitis.

Oil of sandal-wood may be given in *doses* of from 10 to 20 drops (Gm. 0.60–1.30) three times a day, according to the degree of inflammation present. It has been administered in capsules, or in mixtures such as the following: $\mathcal{R}$. Oil of sandal-wood $\text{f}\overline{\text{ss}}$; dilute alcohol $\text{f}\overline{\text{ijss}}$; oil of cinnamon $\text{m}\overline{\text{xxv}}$.— $\mathcal{M}$. $\mathcal{S}$.—1 or 2 teaspoonfuls two or three times a day. It may also be given mixed with powdered liquorice in wafers.

OLEUM SASSAFRAS, U. S.—OIL OF SASSAFRAS.*Essence de sassafras*, Fr.; *Sassafrasöl*, G.The volatile oil distilled from the wood of *Sassafras officinale*, *Nees*.*Nat. Ord.*—Lauraceæ.

Preparation.—Oil of sassafras is distilled in Maryland and various other parts of the United States, mostly in the neighborhood of those places where a supply of the root may be obtained without requiring much transportation. The stills used are made of copper or iron, and usually connected with a lead condenser. The roots, together with the adhering bark, are cut into chips, about 10 bushels of which constitute a charge, and yield on an average about 4 pounds of the oil, the distillation requiring about 12 hours (Procter, 1866). If the root is dug up shortly after the tree has been cut, it appears to yield a colorless or yellow oil, but if the stumps are permitted to remain in the ground for some time they acquire a red color and yield a brown-red oil.

Properties.—As stated, oil of sassafras is either colorless or more frequently of various shades of yellow or brown-red, a difference which does not affect its quality. When carefully rectified it may be obtained colorless, but on exposure again becomes colored. It has the odor of sassafras in a high degree, a warm aromatic taste, a neutral reaction, and a slightly dextrogyre rotatory power. Its specific gravity is usually about 1.090, and increases somewhat by age. It dissolves small quantities of water, becoming lighter thereby. It is freely soluble in alcohol, dissolves in 4 or 5 parts of 80 per cent. alcohol, acquires with cold nitric acid a dark-red color, being finally converted into a red resin, and is violently acted on by bromine, but dissolves iodine quietly.

Composition.—According to Grimaux and Ruotte (1869), potassa solution extracts from oil of sassafras a body which appears to be a phenol, has the odor of eugenol, and assumes a bright-green color with ferric chloride. By fractional distillation a hydrocarbon, *safrene*, $C_{10}H_{16}$, is obtained, which boils between 155° and 157° C. (311° and 314.6° F.), and is dextrogyre. The oxygenated portion, *safrol*, $C_{10}H_{10}O_2$, constitutes nine-tenths of the oil, is without action on polarized light, distils between 230° and 235° C. (446° and 455° F.), remains liquid at -20° C. (-4° F.), and yields with bromine crystals of $C_{10}H_3Br_3O_2$. On cooling the oil in a freezing mixture Saint-Evre (1843) obtained crystallized *sassafras-camphor*, $C_{10}H_{10}O_2$, which remained solid at 5° C. (41° F.), and after being fused congealed again at 7.5° C. (45.5° F.).

Off. Prep.—Trochisci cubebæ, U. S.

Medical Action and Uses.—The action and uses of this oil do not differ materially from those of numerous other essential oils. It is alleged, however, to prevent the usual effects of tobacco when mixed with it and smoked, and the narcotic action of hyoscyamus when associated with that drug. The *dose* is from 2 to 10 drops (Gm. 0.10–0.60).

OLEUM SESAMI, U. S.—OIL OF SESAMUM.*Benne oil*, *Gingili oil*, *Teel oil*, E.; *Huile de sésame*, Fr.; *Sesamöl*, G.

The fixed oil expressed from the seeds of *Sesamum indicum*, *Linne*. Bentley and Trimen, *Med. Plants*, 198.

Nat. Ord.—Pedaliaceæ.

Origin.—Benne is an annual herb which is indigenous to India, but is now not found in the wild state; it is largely cultivated in most tropical countries and in the warmer portions of the temperate zone. It grows from 2 to 5 feet (0.6–1.5 M.) high, and has an erect, branching, bluntly quadrangular, and hairy stem, alternate or sub-opposite leaves, and short-stalked axillary flowers, with large white bell-shaped five-lobed and somewhat two-lipped corollas. The fruit is capsular, two-valved, four-celled, quadrangular and linear-oblong in shape, and contains numerous seeds, which are small, flattened, oval or ovate, smooth and shining, vary in color between whitish, yellow, reddish-brown, and blackish, have a sweetish oily taste, and contain a straight embryo with a short radicle and large plano-convex oily cotyledons. *Sesamum orientale*, *Linne*, is now regarded as being identical with this species.

SESAMUM, U. S. 1870.—Benne, Sesame-leaves, E.; Feuilles de sesamé, Fr.; Sesamblätter, G.—The leaves are mostly employed in the fresh state. They are from 3 to 5 inches (75–125 Mm.) long, long-petiolate, ovate or lance-oblong in outline, narrowed or rounded or somewhat heart-shaped at the base, more or less pointed above, entire on the margin or irregularly toothed, and the lower ones frequently cut into three-toothed lobes

or distinct leaflets. The leaves are prominently veined on the lower surface, are smoothish or somewhat pubescent, and have a mucilaginous taste. Their principal constituent is mucilage, which is precipitated from its aqueous solution by alcohol.

Preparation.—Oil of benne is obtained by subjecting benne-seeds to pressure; the yield is in the neighborhood of 50 per cent. of the weight of the seeds. About 14,000 gallons of this oil were imported into the United States in 1876, and 126,271 gallons in 1883.

Properties.—Benne oil has a yellow color, usually of a deeper hue than expressed almond oil, is thinner at ordinary temperatures than most other fixed oils, is nearly inodorous, and has a bland and agreeable peculiar taste, and the specific gravity 0.923 at 15° C. (59° F.). Near the freezing-point of water it becomes opaque, and congeals usually at about -5° C. (23° F.), while the oil extracted by solvents congeals at about 5° C. (41° F.), forming a yellowish-white mass; when heated to between 150° and 200° C. (302° and 392° F.) it is decolorized. At 300° C. (572° F.) it assumes a brown color, and at 335° C. (635° F.) it commences to boil. It is a non-drying oil, and on exposure to air does not readily turn rancid. Concentrated sulphuric acid converts it into a brown-red gelatinous mass; nitric acid specific gravity 1.18 colors it gradually orange-yellow, and when of greater strength, red; with a mixture of nitric and sulphuric acid it is transiently colored green, afterward red and brown-red; in contact with nitrous acid it becomes reddish and brown-red, and gradually forms a semi-solid mass.

Composition.—Flückiger (*Pharmacographia*) found benne oil prepared by himself to contain 76 per cent. of olein; the acids of the solidifying portion appear to be stearic, palmitic, and myristic acids. A small quantity of a peculiar, probably resinous, substance may be extracted from the oil by agitation with glacial acetic acid or with alcohol; the acetic solution acquires a greenish-yellow, the alcoholic solution a blue afterward greenish-yellow, color on the addition of a cold mixture of equal weights of sulphuric and nitric acids. (See also p. 1033.)

Allied Oils.—The following four oils are obtained from seeds of the natural order Leguminosæ:

KERUNG OIL is thickish, yellow, of the specific gravity .945, and begins to become turbid near 7° C. (44.5° F.). It comes from an East Indian tree, *Pongamia glabra*, Ventenat, s. *Dalbergia arborea*, Roxburgh, the odorless root and leaves of which are also used medicinally. The seeds are gray and kidney-shaped.

GROUND-NUT OIL, PEANUT OIL.—Huile de pistache de terre, Fr.; Erdnussöl, G.—It is prepared from *Arachis hypogæa*, Linné (Bentley and Trimen, *Med. Plants*, 75), an annual herb indigenous to tropical America and now cultivated throughout the tropics; it is known in Brazil as *amendoim* or *mandobim*. The seeds contain about 45 per cent. of oil. This is pale-yellow, thin, has the density .920, and a peculiar nutty flavor, becomes turbid at about 3° C. (37.4° F.), and congeals near -5° C. (23° F.). Nitrous acid causes the oil to congeal to a whitish mass; nitric acid colors it reddish, and sulphuric acid grayish-yellow, then green-brown. It consists of the glycerides of palmitic, arachic, and hypogæic acids. The latter is $C_{16}H_{30}O_2$, and crystallizes in needles which melt near 35° C. (95° F.). Arachic acid, $C_{20}H_{40}O_2$, melts at 75° C. (167° F.). Under the name of *katchung oil* this oil is largely used in India in the place of olive oil.

SOY OIL is prepared from *Soja hispida*, Moench, s. *Dolichos Soja*, Linné. The plant is indigenous to Japan, and largely cultivated in Southern Asia for its brownish or whitish ovate-reniform seeds, which are used as food, and for preparing a sauce called *soy*; when fresh they contain 14 to 16 per cent. of moisture and from 16 to 18 per cent. of a bland yellowish oil.

NICKER-SEED OIL, from *Cesalpinia* (*Guilandina*, Linné) *Bonducella*, Roxburgh. The seeds of this tropical climber, which are also known as *bonduc nuts*, are somewhat compressed, sub-globular, or oblong, about $\frac{3}{8}$ inch (15 Mm.) broad, bluish or ashy gray, slightly ridged, and have a bitter taste. The expressed oil is used for embrocations. The seeds are used in India as a tonic and anti-periodic; they contain a white bitter principle soluble in ether and alcohol and slightly soluble in water (*Pharmacographia*). The bark of bonduc-root is likewise employed as a tonic.

BEN OIL, BEHEN OIL, is expressed from the seeds of *Moringa pterygosperma*, Gaertner (Mor. oleifera, Lamarck, *Guilandina Moringa*, Linné), and one or two allied East Indian trees of the nat. ord. Moringaceæ. The bark of the root has an odor and taste resembling horseradish. The seeds, known as *ben nuts*, are triangular-globose, pitted, and have elongated membranous wings on the angles; the seeds of *Moringa aptera*, Gaertner, are without wings; both are acrid, bitter, and emetic. They yield about 30 per cent. of fixed oil, which is yellowish, inodor-

FIG. 200.

Sesamum indicum, Linné: a, flowering branch; b, section of seed.

ous, bland, or if expressed at an elevated temperature somewhat bitter, acrid, and purgative. It retains its neutral reaction for a long time. It solidifies at about 0°C . (32°F .), but below 7°C . (44.6°F .) it deposits solid fats: the portion remaining liquid is used for extracting delicate perfumes from flowers. Oil of ben consists of the glycerides of moringic, oleic, myristic, palmitic, stearic, and behenic acids. *Moringic acid*, $\text{C}_{15}\text{H}_{28}\text{O}_2$, is liquid, and crystallizes at 0°C . (32°F .). *Behenic acid*, $\text{C}_{22}\text{H}_{44}\text{O}_2$, is crystalline, melts at 76°C . (168.8°F .), and solidifies at 70°C . (158°F .).

The slowly-drying bland or slightly-pungent oil expressed from the seeds of *Camelina sativa*, Crantz, s. *Myagrum sativum*, Linné (Leindotter, G.), is sometimes called *German sesame oil*.

Medical History and Uses.—Sesamum was anciently ranked among the most nutritious grains, and as tending especially to fatten, but it was also considered difficult of digestion. Hippocrates recommended consumptives to use bread made of it instead of wheat, and in pulmonary catarrhs prescribed an emulsion prepared with sesame, almond, and melon-seeds. To this day it serves to make bread in the East. Its oil was anciently used, and in India continues to be employed, for the same purposes as olive oil, but it has always been regarded as less agreeable and as less digestible. Externally, the bruised or ground seeds were applied in maturative poultices, and a decoction prepared with them was held to be emmenagogue and abortive. No mention is made by ancient writers of the mucilage of the young leaves. The seeds of sesame are used by the negroes of South Carolina in making broths, and are also eaten by them parched. The oil, which is very bland, is applied to the same purposes as olive oil. The mucilage is generally prepared from the fresh young leaves by infusing them in cold water. It is justly esteemed as a demulcent drink in *cholera infantum*, *dysentery*, and other disorders of the bowels.

Pongamia glabra furnishes the *kurung oil* which is employed in Hindostan in the treatment of various *skin diseases*. Pityriasis versicolor is mentioned as one of those in which it is efficient (*Amer. Jour. Phar.*, May, 1883, p. 267).

OLEUM SINAPIS VOLATILE, U. S.—VOLATILE OIL OF MUSTARD.

Oleum sinapis, Br., P. G.; *Oleum sinapis æthereum*.—Oil of mustard, E.; *Essence de moutarde*, Fr.; *Ätherisches Senföl*, G.

The volatile oil distilled from the seeds of *Sinapis* (*Brassica*, Koch) *nigra*, Linné.

Nat. Ord.—Cruciferae, Siliculosae.

Preparation.—Black mustard-seeds are ground, deprived of most of their fixed oil by pressure, macerated with water at the common temperature, and then distilled. A small quantity of ground white mustard-seed is usually added to supply any possible deficiency of myrosin and ensure the decomposition of all the myronic acid. Since oil of mustard is soluble in water, the aqueous portion of the distillate is used in macerating a fresh portion of mustard. The yield is usually about $\frac{1}{4}$ per cent., but occasionally as high as 1 per cent. Direks (1883) obtained the following yield: black mustard-seed cake, 1.39 per cent.; rape-seed, .018 to .037; rape-seed cake, .020 to .109; yellow mustard-seed cake, .018; turnip-seed, .038; seed of *Sinapis arvensis*, Linné, .006. According to A. W. Hofmann (1882) the oil is best prepared artificially by boiling sulpho-urea with concentrated phosphoric acid.

Properties.—The crude oil has a yellow color; after rectification it is colorless or nearly so. It is neutral to test-paper, has the specific gravity 1.017 (1.016–1.022 *P. G.*, 1.017–1.021 *U. S.*), has no effect on polarized light, boils at 148°C . (298.4°F .), is somewhat soluble in water, freely so in alcohol and ether, and has a very pungent and acrid odor and taste. The oil dissolves completely in 3 parts and more of cold concentrated sulphuric acid without coloration, the mixture retaining a light-yellow color and remaining perfectly transparent; sulphurous acid gas is given off, the liquid becomes thicker, sometimes crystalline, and the piercing odor of mustard oil disappears; in the presence of other volatile oils a brown or red color is produced. Ammonia converts the oil into *thiosinamin* or *allylsulpho-urea*, $\text{C}_3\text{H}_5\cdot\text{NH}\cdot\text{NH}_2\cdot\text{CS}=\text{C}_6\text{H}_5\cdot\text{N}_2\text{S}$, which crystallizes in colorless rhombic prisms having a bitter taste, melting at 70°C . (158°F .), and easily soluble in water, alcohol, and ether. This reaction was recommended by Flückiger (1880) as a quantitative test for the oil (see below).

Composition.—Oil of mustard is *sulphocyanide of allyl*, $\text{C}_3\text{H}_5\cdot\text{CNS}$. Sometimes it contains also allyl cyanide and carbon disulphide, the latter, according to A. Hofmann, not exceeding .56 per cent., while Johanson (1881) found from .76 to 2 per cent.; both these compounds boil at a lower temperature. The oil is artificially prepared by decomposing allyl bromide or iodide by means of an alcoholic solution of potassium sulpho-

cyanide. Using an allyl iodide obtained from glycerin and phosphorus iodide, Gerlich (1875) obtained a mustard oil which consisted of *isopropyl sulphocyanide*, $C_3H_7.CNS$, the density of which is 0.974. Mylius (1877) found in the artificial oil of commerce, besides 92.2 per cent. of allyl-mustard oil, some hydrocyanic acid, carbon disulphide, and polysulphides.

Tests.—The oil should not begin to boil below $148^{\circ} C.$ (carbon disulphide boils at 48° , alcohol at 78° , allyl cyanide at $118^{\circ} C.$), and the first fraction of the distillate should have the same density as the oil. A mixture of 3 Gm. of oil of mustard, 3 Gm. of alcohol, and 6 Gm. of ammonia, heated to 50° ($122^{\circ} F.$), gradually becomes clear, and on careful evaporation in a water-bath should leave between 3.25 and 3.50 Gm. of thiosinamin, having a brownish color, a leek-like but not acrid odor, a bitterish not persistent taste, and being soluble in 2 parts of warm water.—*P. G.*

Pharmaceutical Uses.—*SPIRITUS SINAPIS, P. G.*—Spirit of mustard, *E.*; Senfspiritus, *G.*—is a solution of 1 part of oil of mustard in 49 parts of alcohol.

Off. Prep.—Liniment. sinapis comp., *U. S., Br.*

Medical Action and Uses.—Volatile oil of mustard is a powerful and almost caustic irritant, which, for fear of accident, should never be prescribed internally. It is said that it may sometimes be applied as an external counter-irritant upon parts to which a blistering plaster cannot readily be adapted, but there are none upon which cantharidal collodion cannot as readily be painted as this oil. As a rubefacient it may be used dissolved in olive oil or alcohol in the proportion of about 5 drops to the fluidrachm (Gm. 0.30 in Gm. 4).

OLEUM SUCCINI, *U. S.*—OIL OF AMBER.

Huile volatile de succin, Fr.; Bernsteinöl, G.

The volatile oil obtained by the destructive distillation of amber and purified by rectification.

Origin.—*SUCCINUM, AMBRA FLAVA.*—Amber, *E.*; Succin, Ambre jaune, *Fr.*; Bernstein, Agtstein, *G.*—This fossil resin is the exudation from a number of extinct coniferous trees of the sub-orders *Abietæ* and *Cupresseæ*, the principal source of the Baltic amber being *Pinites succinifer*, *Goeppert*, s. *Pityoxylon succiniferum, Kraus*. It is principally obtained on the southern and south-eastern coast of the Baltic, where it is cast ashore or dug out of beds. It has also been found in the interior of Europe and in Siberia, Greenland, and North America. It is hard, somewhat brittle, whitish, yellow, or red-brown, transparent, translucent, or opaque, breaks with a conchoidal fracture, and frequently encloses vegetable fragments and insects. It is fragrant when heated, melts at about $287.5^{\circ} C.$ ($550^{\circ} F.$), dissolves in chloroform, but is insoluble in water, and only partly soluble in alcohol, ether, and volatile oils. Its density varies between 1.05 and 1.10. The annual production of amber in Prussia is estimated at 100,000 kilos. From 4000 to 7000 pounds of oil of amber are annually imported by the United States.

Preparation.—The oil is obtained by the dry distillation of amber, succinic acid being formed at the same time (see page 95). The crude oil is mixed with six times its volume of water, and distilled as long as oil is found in the distillate. The yield is usually stated to be from 60 to 70 per cent. of the crude oil; but Ebert (1865), who prepared the crude oil, obtained from 29 troyounces of amber 21 fluidounces of oil specific gravity 0.985, and on rectifying this with water only $2\frac{1}{2}$ fluidounces, or about 12 per cent. of rectified oil specific gravity 0.903, while the density of the residue had increased to 1.019. Marsson (1850) obtained from amber 6 per cent. of rectified oil, 3.5 per cent. of succinic acid, and 58.3 of residuary resin (amber colophony). Döpping (1847) observed that the crude oil, after having been treated with potassa solution, dilute sulphuric acid, caustic potassa, and calcium chloride in succession, distilled between 140° and $170^{\circ} C.$ (284° and $338^{\circ} F.$) and left a dark-brown residue. On again treating the distillate with burned lime, and repeating the distillation, the liquid had a higher boiling-point (up to $190^{\circ} C.$, $374^{\circ} F.$) and was colorless.

Properties.—Crude oil of amber is a thick brown liquid of a strong empyreumatic and fetid odor, and variable specific gravity approaching the density of water; Marsson found it to be .922. Very similar products are obtained from copal, dammar, and other resins. In this state it is rarely employed in medicine, but is used in preparing

OLEUM SUCCINI RECTIFICATUM, Rectified oil of amber. This is thin, colorless or yellowish, becomes darker and thicker on exposure, has a spec. grav. of about .920, but varies in density between 0.88 and 0.99, and in the boiling-point as stated above. It has a pun-

gent, empyreumatic, and somewhat balsamic odor, which is more pleasant than that of the crude oil, and a warm, acrid taste. It has a neutral or faint acid reaction, dissolves, according to Anthon (1835), in 2 parts of absolute alcohol, but requires at about 35° C. (95° F.) 30 parts of alcohol spec. grav. .855 for complete solution. Ebert found it soluble in 4 parts of alcohol spec. grav. .817, and in 17 parts of alcohol spec. grav. .835. It is readily soluble in ether, fixed and volatile oils, dissolves iodine, and, when heated, sulphur and caoutchouc. It absorbs some hydrochloric acid gas without forming a crystalline compound, and in contact with cold fuming nitric acid acquires a red afterward dark red-brown color, and is converted into a brown resinous mass having a peculiar musk-like odor, and formerly known and medicinally employed under the name of *artificial musk*. It was discovered by Marggraf (1759), and may also be obtained from oil of amber and ordinary or diluted nitric acid on the application of heat.

Composition.—In its purest state oil of amber is a mixture of several oils having the composition of oil of turpentine, $C_{10}H_{16}$.

Adulterations.—Oil of amber is not unfrequently adulterated with oil of turpentine and with coal oil; the former is recognized by the brisk reaction with iodine, and by the formation of terpin when left in contact with alcohol and nitric acid; the latter by the decreased solubility in alcohol.

Medical Action and Uses.—Oil of amber is a powerful irritant of the skin. When taken internally it is said to be stimulant and anti-spasmodic. It has been so given in various *mucous profluxa* of the lungs and urinary organs, in *retrocedent gout* and *rheumatism*, *eruptive fevers*, *hysteria*, *whooping cough*, and *amenorrhœa*. Externally, it may be employed in stimulating liniments for *rheumatism* and *paralysis* and rubbed upon the spine in the *convulsive disorders* of children. It has been applied as a stimulant discutient to *hemorrhoidal tumors*. The dose is from 5 to 10 drops (Gm. 0.30–0.60), and on account of its acrid and offensive taste the oil should be enclosed in gelatin capsules.

OLEUM TEREBINTHINÆ, U. S., Br., P. G.—OIL OF TURPENTINE.

Essence de térébenthine, Fr.; *Terpentinöl*, G.

The volatile oil distilled from turpentine. (See TEREBINTHINA.)

Preparation.—Oil of turpentine is obtained by distilling the oleoresinous exudation of various species of *Pinus*. The crude turpentine is put into a large still, heat is applied, and a little water added from time to time to the contents of the still. The distillation is continued as long as oil passes over, when the resinous mass is run off through a stop-cock placed at the bottom of the still, is passed through several strainers, and then constitutes *rosin*. (See RESINA.) On condensing the distillate the oil of turpentine separates from the water and is dipped into barrels, in which it enters commerce.

Properties.—Oil of turpentine is a colorless, thin, volatile oil, the density of which varies between 0.855 and 0.87. When recently rectified it boils at about 150° C. (302° F.), but the temperature usually rises as the distillation progresses, and old oil does not generally commence to boil below 155° or 160° C. (311° or 320° F.). As procured from different sources, oil of turpentine shows great differences in its optical behavior, and on fractional distillation with or without water oils are obtained differing in the degree of their influence upon polarized light. American and German oil of turpentine are dextrogyre, while the French oil has a levogyre action. Odor and taste are peculiar, strongly terebinthinate, differing to some degree according to the source from which the oil has been obtained. When recently distilled, particularly after rectification with water, the oil has a neutral reaction and its odor is rather mild, but after exposure to air it becomes stronger, more unpleasant, and pungent; the oil then contains ozone, and gradually acquires a yellowish color and thicker consistence; at the same time resin and formic and acetic acids are produced, and, in the presence of moisture, also a hydrate of the oil. The aqueous solution of such oxidized oil has been used under the name of *sanitas* as an antiseptic; on evaporating it Kingzett (1880) obtained a dark-colored adhesive mass, $C_{10}H_{15}O_2$, which with sulphuric acid gave a dark-red color. Oil of turpentine dissolves in $\frac{1}{2}$ or $\frac{2}{3}$ part of alcohol sp. gr. .816, in $1\frac{1}{2}$ or 2 parts of alcohol sp. gr. .820, in 4 or 5 parts of alcohol sp. gr. .830, and in from 8 to 12 parts of alcohol sp. gr. .845; the solubility of oil of different origin and age varies more or less, and occasionally oil of turpentine has been observed which even with strong alcohol would not yield a perfectly clear solution. Bromine and powdered iodine act violently upon oil of turpentine; nitric acid oxidizes it, the violence of the action and the final products being influenced by the strength of the acid. Gaseous hydrochloric acid unites with oil of turpentine, forming two compounds: one, having

the composition $C_{10}H_{16}HCl$, is known as *artificial camphor*, is crystallizable, and has the odor and taste of ordinary camphor, but is less pungent and somewhat terebinthinate. Three compounds with water are known; one, which is called *turpentine camphor* or *terpin*, has the composition $C_{10}H_{20}O_2$, and is obtained by leaving the oil in contact with alcohol and nitric acid.

Purification.—Only rectified oil of turpentine should be used internally. The partially resinified oil is best purified by rectification with water, or it may be repeatedly agitated with small portions of alcohol, which dissolves the resin, and afterward with water. The following is the formula of the German Pharmacopœia:

OLEUM TEREBINTHINÆ RECTIFICATUM.—Rectified oil of turpentine, *E.*; Essence de térébenthine rectifiée, *Fr.*; Gereinigtes Terpentinöl, *G.*—Agitate oil of turpentine 4 parts with lime-water 24 parts, and distil until 3 parts of oil have passed over; separate the clear oil from the water. Its solution in alcohol should not change the color of moist litmus-paper.

Composition.—When perfectly pure, oil of turpentine is free from oxygen and has the composition $C_{10}H_{16}$. On being distilled in the presence of sulphuric acid it is converted into several isomeric or polymeric oils, among which are *terebene* and *colophene*, the latter boiling at $310^{\circ} C.$ ($590^{\circ} F.$) and showing a blue fluorescence; it is also obtained on the dry distillation of rosin. By acting with sodium on turpentine hydrochlorate Letts (1879) obtained *turpenyl*, $C_{10}H_{17}$, a solid white volatile compound, and *diturpenyl*, $C_{20}H_{34}$, which is liquid and has a higher boiling-point.

Off. Prep.—Confectio terebinthinæ. Enema terebinth., *Br.*; Linim. cantharidis, *U. S.*; Linim. terebinth., Linim. terebinth. acetikum, Unguent. terebinthinæ, *Br.*

Allied Products.—TEREBENE, $C_{10}H_{16}$. It is a derivative of oil of turpentine, produced by the action of heat and of concentrated sulphuric acid or phosphoric anhydride. It is a colorless volatile oil, without influence on polarized light, has a rather agreeable thyme-like odor, the density .864 at $8^{\circ} C.$ ($46.4^{\circ} F.$), and the boiling-point $156^{\circ} C.$ ($312.8^{\circ} F.$), and acquires with iodine a dark-green, opaque appearance. It combines with hydrochloric acid gas, forming two liquid oils, one of which is heavier than water.

ABIETENE, $C_{11}H_{18}$. This is the volatile oil obtained from the terebinthinate exudation of *Pinus Sabiniæ*, *Douglas*, the *nut pine* or *digger pine* of California. According to Wenzell (1872), the crude oil is colorless, and commences to boil at $101^{\circ} C.$, the thermometer gradually rising to $115^{\circ} C.$ ($239^{\circ} F.$). Pure abietene boils at $101^{\circ} C.$, has a strong penetrating orange-like odor, is highly inflammable, very volatile, of the spec. grav. .694 at $16.5^{\circ} C.$, soluble in 5 parts by measure of 95 per cent. alcohol, dissolves freely iodine and bromine, and yields with chlorine a substitution-compound boiling at $260^{\circ} C.$ Thorpe (1879) found it to have the composition of *heptane*, C_7H_{16} , to boil at $98.42^{\circ} C.$, and to be slightly dextrogyre.

The volatile oil of *Pinus ponderosa*, *Douglas*, of California, which was examined by Sadtler (1879), seems to have the same composition.

Physiological Action.—Numerous experiments upon animals prove that oil of turpentine, however applied, is rapidly absorbed, and produces, according to the quantity employed, more or less of its characteristic effects; *e. g.* stimulation of the nervous system when relatively small doses are used, and paralyzing effects when large quantities are administered. The urine is increased and may be rendered bloody, the animals lose their muscular force and co-ordination, the breathing is laborious, and the action of the heart quickened. Death takes place by exhaustion and asphyxia. Binz has shown that large doses of it prevent or control the spasms excited by brucine. Its local operation is that of an irritant, causing pain, redness, and even vesication. In man the prolonged inhalation of its vapors produces vertigo, impaired vision, pain in the loins, strangury, and bloody urine, and, if very concentrated, a state of collapse. In females menorrhagia and dysmenorrhœa are sometimes added. Workmen when first exposed to its emanations suffer from headache, unsteady gait, irritability, smarting of the eyes, and lachrymation, impaired vision (particularly by artificial light), coryza, cough, granular pharyngitis, vomiting, and indigestion. Gradually, however, these symptoms subside and a tolerance of its action is established (*Bull. de thérap.*, xvi. 508). The internal administration of large doses of the oil has produced heat in the stomach, vertigo, confusion of mind, extreme thirst, strangury, and a frequent discharge of urine exhaling an odor of violets. It is secreted with the milk. The bowels are not disturbed. Sometimes it causes itching and diaphoresis. Excessive or poisonous doses occasion graver symptoms. Thus, when 6 ounces were taken by a woman her body was found in a state of opisthotonos, the pupils were dilated, and the brain, lungs, stomach, and heart were gorged with blood. Yet a child aged fourteen months recovered after swallowing 4 ounces of the oil. It is recorded that the air of a cellar where turpentine was stored,

and in which a boy was nearly asphyxiated, was found to be nearly deprived of its oxygen. Many instances of its narcotic action are on record. (Compare Begbie, *Works*, p. 283.)

Medical Uses.—Oil of turpentine has been used in almost every form of *hæmorrhage*, but most successfully when the bleeding was passive. The special affections include *epistaxis*, *hæmatemesis*, *hæmaturia*, *menorrhagia*, *post-partum hæmorrhage*, *purpura*, and the multiple hæmorrhages occurring under the influence of the *hæmorrhagic diathesis*. Even in external and traumatic hæmorrhages it has proved efficient. Its efficacy justifies the opinion of John Hunter, who termed it “the best, if not the only true, styptic.” A cure of *aneurism* has even been attributed to its internal administration (*Times and Gaz.*, Nov. 1883, p. 543).

In *puerperal fever* this medicine once enjoyed a high repute, which it has in a great measure lost at the present time. For the varying estimates of its value a reason may probably be found in the indiscriminate manner of its employment. When it was prescribed in cases marked by a typhoid state in which excessive tympanites existed, there is no reasonable ground for doubting that it often successfully combated the nervous and cardiac depression of the disease, and, by lessening the distension of the abdomen, diminished the mechanical hindrances to hæmatosis. For the latter purpose it was applied as an epithem to the abdomen, as well as administered internally. This judgment appears to be justified by its recognized effects in other febrile affections of a typhoid type. In *typhus*, for example, it is of great utility both internally and externally—not only for its power of arousing the sluggish functions generally, but especially for combating the pulmonary congestion which is the gravest of the usual incidents of the disease. In *typhoid fever*, besides the general influences already mentioned, it is not only one of the most efficient remedies for intestinal tympanites, as in the cases referred to, but it also favorably controls the bronchial catarrh, and, in the advanced stages, probably exerts a local stimulant action upon the intestinal ulcers and checks the tendency to hæmorrhage from them. So, too, in *yellow fever* of a low type it may operate not only by its general stimulation, but also by its direct action upon the stomach, tending to control the hæmorrhage which is so grave a symptom in that disease. Its possible action in promoting the urinary secretion in this fever should not be overlooked. In *tympanites*, from whatever cause arising, it may become a valuable auxiliary in the treatment, whether administered by the mouth or rectum or applied to the skin of the abdomen. When given internally for the relief of this symptom it should generally be associated with a purgative, and especially with castor oil. It is most efficient in the treatment of *tænia*, and indeed in that of other *intestinal worms*, when a full dose of it is shortly followed by one of castor oil. A disadvantage of this treatment is, however, that as large doses of the oil are required they are apt to give rise to colic, if not to strangury.

Oil of turpentine has been supposed to dissolve *biliary concretions*, and in some cases it has, when associated with sulphuric ether, appeared to favor their discharge. It seems more probable that it should tend to prevent the formation of gall-stones than to dissolve them when once formed. Its diuretic virtues have caused it to be occasionally used to promote the expulsion of *urinary concretions*, and for this purpose it is said to have been efficacious in the form of baths of the vapor of oil of turpentine (Brémond). Impregnating the urine, it becomes a suitable remedy for *catarrh of the urinary passages* and for debility or *paralysis of the bladder*; and, very probably, in females this stimulation has served to cure *amenorrhœa* and to excite *uterine contractions* during labor. For these purposes, however, the oil is best administered by the rectum.

Although the *modus operandi* of this medicine in *sciatica* is totally unknown, its curative power is none the less certain. It has stood the test of a century's experience. Probably no other remedy is comparable with it in chronic examples of this painful and crippling affection. Some difference of opinion exists concerning the proper dose which should be given, some prescribing $\frac{1}{2}$ ounce of it at bedtime for several successive nights, and others a dose of 30 drops three times a day. The latter is to be preferred at first. It may be gradually increased if necessary. The cases which are benefited by this treatment are more apt to occur in feeble than in robust persons, and are the effect of a prolonged rather than an abrupt action of cold and dampness. It has also been used in *facial neuralgia*, but apparently with inferior results. Its utility in *syphilitic iritis* is well established: it has generally been employed as a substitute for mercury in cases for which this medicine was ill adapted.

In all forms of *chronic bronchitis* oil of turpentine has, like other terebinthines, been largely used, formerly by internal administration, and more recently by inhalation. It is especially useful in both ways in cases of *fetid bronchitis* and *gangrene of the lung*, in both,

doubtless, by stimulating the tissues to a more healthy action rather than by any disinfectant virtue. The superiority of oil of turpentine in the latter affection is certainly due to its stimulant virtues. An atomized solution of 15 drops of oil of turpentine in sufficient water is recommended to be inhaled for about 10 minutes every hour, day and night, in the treatment of *diphtheria* (Edel). Bosse claims to have treated this disease very successfully by oil of turpentine given internally in doses of 2 or 3 drachms a day (*Times and Gaz.*, Jan. 1881, p. 101). Satlow states that the first effect of the oil is to remove the fœtor, and then to render the exudation looser, softer, and thinner, and cause it to be thrown off, leaving no trace behind it. The full action of the remedy occupies 3 or 4 days. Of forty-three cases treated by Satlow, only one died, and that was of a paralytic sequel of the disease. He advises that only freshly-prepared oil be employed, and that doses to the extent of a teaspoonful daily should be given to children under two years of age, and of a dessertspoonful to those between that age and five years, and to adults a tablespoonful, and that each dose should be followed by a draught of milk (*Centralbl. f. d. ges. Therapie*, i. 447). It is worthy of remark, first, that the use of this mode of treatment was discovered through a child affected with diphtheria having accidentally swallowed a tablespoonful of oil of turpentine; and, second, that the most plausible explanation of its utility is, that it not only acts directly upon the membrane, but also as a stimulant to the whole system, as it does in adynamic states generally. It has naturally been referred to the power of oil of turpentine to destroy disease-germs, but the explanation is as inadequate as it is unnecessary. The vapors of this oil are also reported to be very efficient in *whooping cough*. The accidental discovery of the power of oil of turpentine to prevent *phosphorus-poisoning* has saved many lives. The immediate administration of the antidote is of course desirable, not only to check the local action of the phosphorus, but also to prevent its absorption in a dangerous form. About 12 hours has been assigned as the limit within which the oil is efficacious. It is alleged that oil of turpentine which has become oxygenated by long exposure to the air is the most efficient, but results do not entirely agree upon this point. It must not be prescribed in an oily or albuminous vehicle, such as white of egg, milk, soup, etc., and neither mucilaginous nor alcoholic drinks should be allowed, but only water. If possible the oil should be given pure, floated on water or in capsules. If it cannot be retained by the stomach, it may be thrown into the rectum, and its absorption by the skin from liniments and epithems, and by the lungs from an atomized preparation or simply from the air of the chamber saturated with the fume of the oil, may be employed as supplementary means. The dose of oil of turpentine in the cases now considered is about 10 drops (Gm. 0.60) every hour.

Oil of turpentine has long been employed *externally* as a stimulant, rubefacient, and counter-irritant in *neuralgia* and in *acute and chronic rheumatism*. It is generally mixed with olive oil, chloroform, camphor, narcotic extracts, etc. Baths of the vapor of the oil are the most efficient means of applying it, or baths of hot watery vapor (104° to 113° F.) with which a fine spray of oil of turpentine is mingled. Warm water baths in which has been dissolved a mixture of 8 ounces of turpentine and 2 pounds of washing soda have also been used with good effect. The oil is of singular virtue in relieving *tympanites* and *colic* in various diseases, but especially when the intestinal distension is owing chiefly to atony of the bowels, as in typhoid fever. It is best applied, mixed with olive oil, to the skin, which should then be covered with flannel dipped in hot water and wrung nearly dry. In the treatment of *burns* this oil is most efficient. The affected part should first be bathed with the oil, and then covered with soft lint saturated with liniment of turpentine or ointment of turpentine, so as thoroughly to exclude the air. Turpentine epithems are also of marked utility in inflammations of the respiratory organs, including *laryngitis*, *bronchitis*, *pneumonia*, and *pleurisy*. They probably act both as revulsives and through the absorption of the oil. They have also been found efficient in the treatment of *phlegmasia alba dolens*. Traumatic *erysipelas* has been treated advantageously by the ointment just mentioned, and also by simple lotions of oil of turpentine. The same method is equally applicable in cases of *frost-bite* and of superficial *gangrene*. An emulsion containing equal parts of oil of turpentine and tincture of camphor is said to be an efficient dressing for *carbuncles*. Indeed, there are few ulcers of an indolent character that are not benefited by this oil, applied either alone or in an ointment or cerate, as in the simple or compound resin cerate. Ulcers resulting from *mercurial salivation* tend to heal after being touched by the pure oil or washed with an emulsion containing it. It has been used successfully in the treatment of *scabies* and in *ringworm of the scalp*, in the one case destroying the *Acarus scabiei*, and in the other the *Microphyton tonsurans*. Foulis states that the fœtor

of putrefying substances will not adhere to the hands if they are anointed with oil of turpentine (*Edinb. Med. Jour.*, xxvi. 133).

The dose of oil of turpentine as a stimulant is from 5 to 20 or 30 drops (Gm. 0.30–2) three times a day. Such doses are conveniently administered in gelatin capsules. As an anthelmintic from 2 or 4 fluidrachms (Gm. 8–16) may be given at intervals of half an hour until three or four doses are taken. These doses are usually prescribed in an emulsion, with the addition of oil of cinnamon, capcut, or rosemary to diminish nausea. Besides the rubefacient preparations above mentioned, a very efficient one may be made with equal weights of oil of turpentine, acetic acid, and liniment of camphor.

TEREBENE has been employed with striking success as a substitute for carbolic acid in the antiseptic dressing of *wounds, ulcers, burns*, etc. It thoroughly deodorizes the secretions and protects the surface to which it is applied from the contact of the air. It is supposed, like carbolic acid, to destroy morbid germs, since it deprives vaccine virus of its activity. It has been applied pure, and also in the proportion of 1 part to 6 of olive oil.

OLEUM THEOBROMÆ, U. S.—OIL OF THEOBROMA.

Oleum theobromatis, Br.; *Oleum concretum e semine Theobromæ cacao*, F. Cod.; *Oleum (Butyrum) cacao*, P. G.—*Butter of cacao*, E.; *Beurre de cacao*, Fr.; *Kakaobutter*, G.

The fixed oil expressed from the seed of *Theobroma Cacao*, *Linne*.

Nat. Ord.—Sterculiaceæ, Buettneriæ.

Preparation.—In the manufacture of chocolate a portion of the cacao-seeds are deprived of their fat by removing the shells, heating the kernels to about 70° C. (158° F.), and pressing them between hot iron plates; the expressed fat is usually run into rectangular moulds and allowed to congeal. The yield from the different varieties of cacao is from 35 to 45 per cent.

Properties.—Cacao butter is a yellowish fat, gradually turning white by age. It is sufficiently hard at ordinary temperatures to be broken into smaller pieces, but softens by the warmth of the hand and melts when taken in the mouth. It has an agreeable odor and a bland chocolate-like taste, dissolves in ether, acetic ether, and by the aid of heat in strong alcohol, separating again from the latter solution on cooling, with the exception of a small portion which remains dissolved. Its specific gravity is 0.96 to 0.98, but is given by some authors as low as 0.900. It melts between 30° and 35° C. (U. S. P., P. G.), forming a pale-yellow, transparent liquid which congeals at 20.5° C. (69° F.), the temperature rising to about 26.5° C. (79.7° F.). The fusing-point of cacao butter obtained from different commercial varieties of seeds has been determined by Trojanowski (1875) and Lamhofer (1877), and found to vary between 30° C. (86° F.) and 33° C. (91.4° F.). Pelouze and Boudet observed it in one instance as low as 29° C. (84.2° F.).

Composition.—Cacao butter is easily saponified, and yields glycerin, oleic, stearic, and a little palmitic acid (Stenhouse, Specht, and Gossman). Kingzett (1877) pointed out the existence in this fat of an acid having the composition $C_{61}H_{125}O_2$, for which he proposed the name of *theobromic acid*. This acid could not be detected by Vander Beke (1880) and C. Traub (1883); the latter, in addition to the acids mentioned above, determined also the presence of lauric and arachic acids, and regards the firm consistence and low melting-point to be due to the proportions in which these glycerides are combined.

Adulterations.—When mixed with other solid fats the fusing-point and specific gravity do not afford reliable tests for determining such admixtures. The presence of tallow may be detected by burning the oil with a wick for a short time, and then extinguishing the flame, when a peculiar tallow-like odor will be observed. For the detection of adulterations Björkland (1864) proposed to dissolve 2 Gm. of the fat in 4 Gm. of ether at 17° C. (62.6° F.), and to immerse the test-tube containing the solution in water of 0° C. (32° F.); if pure, cacao butter will separate granules in not less than 3 minutes, but usually in 5 or 8 minutes; if adulterated with tallow or suet, a turbidity will appear at once or within 2½ minutes, according to the quantity of the adulterant, of which 5 per cent. may thus be detected. When the congealed mixture is exposed to a temperature of about 14.5° C. (58° F.) it will gradually become clear again if the cacao butter was pure, but not if it was adulterated. Trojanowski and Lamhofer proved the value of this test, which has been adopted by the U. S. P. According to Lamhofer, petroleum benzin may be substituted for the ether with nearly identical results, except that the pure oil separates rather more slowly and is always granular, while other fats render the entire liquid cloudy.

"The solution of 1 part of oil of theobroma in 2 parts of ether should remain clear if kept for a day at a temperature of 12° to 15° C. (53.6° to 59° F.)."—*P. G.* This is a modification of the test proposed by Ramsperger (1876), who states also that aniline shows adulterations with tallow and wax almost as well as ether does.

Off. Prep.—Cacao butter is an ingredient of all official suppositories, except three admitted by the "Additions to the British Pharmacopœia."

Allied Fats.—More or less odorous fats are expressed from the seeds of several species of *Bassia* (nat. ord. Sapotaceæ). *Bassia longifolia*, *Linneé*, yields the greenish *elloopa* or *illoopa* oil. *Bassia butyracea*, *Roxburgh*, gives the tallow-like *fulva* butter. The *mahwah* butter melts at about 45° C. (113° F.), is greenish or yellowish, and comes from *Bassia latifolia*, *Roxburgh*. These fats come from India. The *shea* butter, *gadam* butter, or *bambuk* butter is obtained from *Bassia* (*Butyrospermum*, *Kotschy*) *Parkii*, *De Candolle*, of tropical Africa. It is pale-greenish or grayish, has a cacao-like odor and mild taste, and melts at about 28° C. (82.4° F.). The fleshy mahwah-flowers are used as food and for distilling a spirit; when dry they are said to contain 50 per cent. of sugar.

MAFURA TALLOW has also a cacao-like odor and a mild taste, but it is of a yellowish color and melts at 42° C. (107.6° F.). It is obtained by boiling the seeds of *Trichilia emetica*, *Vahl*, s. *Mafureira oleifera*, *Bertero* (nat. ord. Meliaceæ), of tropical East Africa.

Medical Action and Uses.—Oil of theobroma has been used internally, in doses of from 15 to 30 grains (Gm. 1-2), as a nutrient and emollient remedy in cases of chronic affections of the *lungs* and *bowels*, and externally as a dressing for excoriated surfaces, *wounds*, etc. Its mildness renders it superior to lard for the latter purposes, and it is more emollient than spermaceti. It is the most eligible material for making suppositories. Its slight tendency to become oxidized fits it to protect surgical and other steel instruments from being corroded by exposure to the air.

OLEUM THYMI, U. S., P. G.—OIL OF THYME.

Essence de thym, Fr.; *Thymianöl*, G.

The volatile oil distilled from *Thymus vulgaris*, *Linneé*.

Nat. Ord.—*Labiata*æ.

Preparation.—The flowering herb is distilled with water or steam. The yield varies between $\frac{1}{4}$ and 1 per cent. The oil is largely produced in France, and enters commerce either in the crude state as *huile rouge de thym* (*red oil of thyme*), or rectified as *huile blanche de thym* (*white oil of thyme*). During the year 1876-77 the United States imported 32,707 pounds of the former and 863 pounds of the latter kind; in 1882, 50,914 and 16,486 pounds were imported. The red oil is frequently sold as *oil of origanum*.

Properties.—Crude oil of thyme is of a deep reddish-brown color; the rectified oil is colorless or yellowish, and is the kind directed by the pharmacopœias. It has a strong aromatic odor and a pungent, warm, and afterward cooling taste, dissolves in one-half its weight of alcohol, and varies in density between 0.886 and 0.905. It does not fulminate with iodine.

Composition.—The more volatile portion of oil of thyme consists of two hydrocarbons—*cymene*, $C_{10}H_{14}$, and *thymene*, $C_{10}H_{16}$. The former is also a constituent of oil of cumin (see p. 524). The latter boils between 160° and 165° C. (320° and 329° F.), is levogyre, and yields with hydrochloric acid gas a liquid compound. The stearepten is *thymol*, $C_{10}H_{14}O$, which is probably formed by oxidation; at least, *Lallemand* (1854) reports having received considerable quantities of thymol by passing air through the mixed hydrocarbons for several months. By agitating the commercial oil with soda solution, *Gerrard* (1878) obtained only variable quantities of an oily liquid, but no solid compound, and on exposure to a low temperature no thymol could be obtained; he concludes from this that the thymol is probably frequently extracted from the oil. A similar experience was reported by *J. L. Lemberger* (1882), who obtained from the rectified oil less than 1 per cent., while two samples of red oil yielded 16.67 and 38.75 per cent. of crude thymol.

Tests.—The presence of thymol, according to *Hager* (1882), is conveniently ascertained by spreading half a drop of it, by means of a small cork, upon a glass slide, so as to occupy 4 or 5 square Cm. The thymol begins to separate within 3 or 4 minutes in the central portion of this liquid, in numerous minute bodies recognizable with the naked eye; subsequently they appear also toward the margin, but less numerous. Under the microscope they are at first amorphous, but after an hour or two are easily recognized as crystals. "The solution of oil of thyme in alcohol should not be colored yellowish-brown on the addition of a drop of test solution of ferric chloride."—*P. G.*

Allied Oil.—The volatile oil of *Thymus Serpyllum*, *Linne*, according to E. Buri (1879), contains two phenols which do not congeal at -10° C. (14° F.), and of which one imparts a yellowish-green color to ferric chloride, and yields a sulphonic acid, the salts of which, like the thymol sulphonates, produce with ferric salts an intense blue color. Jahns (1880) reported also the presence of a little thymol and carvacrol.

Physiological Action.—*On Animals:* Experiment has proved that oil of thyme, added to certain fermentable liquids in the proportion of 1 part per 1000, arrests saccharine and powerfully retards lactic fermentation, and checks the various processes of decomposition, even when used in relatively small quantities. Nevertheless, according to Marey, it has a very feeble action as a "germicide." It was speedily fatal when injected into the blood-vessels of dogs or rabbits in an emulsion containing the oil in the proportion of from $\frac{1}{2000}$ to $\frac{1}{1000}$ of the vehicle. From three to twenty times this dose was administered subcutaneously and by the mouth without serious consequences. An emulsion containing from 2 to 5 per cent. of the oil injected into the abdominal cavity caused narcosis and death from respiratory paralysis. In such experiments the temperature of the animals declined from 2° to 6° C. Their blood was dark and fluid, but the proportion of its red corpuscles was not diminished. The urine contained albumen and hyaline casts (Küssner).

On Man: It is comparatively harmless when administered internally, not disturbing digestion, although it arrests gastric fermentation. It is ten times less poisonous than carbolic acid, and hence may be used even in equal quantities with a very inferior risk. Some persons find its taste and smell as repulsive as those of carbolic acid, but others claim for it an agreeable aromatic odor and flavor. When taken internally by sensitive persons it causes ringing in the ears, and even deep somnolence, and collapse.

The following record of experiments will illustrate these differences, showing that they depend very much upon the dose of the medicine: Küssner took about 15 grains (Gm. 1) of thymol in the course of 24 hours in the form of pills, each of which contained $1\frac{1}{2}$ grains (Gm. 0.10) of the oil. The medicine was continued for 4 days. No change was observed in the respiration, pulse, temperature, or urine, but a slight burning sensation was felt in the stomach which continued for nearly a fortnight after the medicine had been suspended. Balz, on the other hand, who gave thymol internally in doses of "30 grains a day or less," states that in a few instances nausea and vomiting were caused; there was copious sweating, with ringing in the ears, deafness, constriction of the forehead, reduction of temperature, and frequently diarrhoea. Violent delirium occurred several times, and in one case of typhoid fever unconsciousness and alarming collapse.

Uses.—The applications of thymol in medicine and *surgery* are identical with those of carbolic acid, to which it appears to be in no degree inferior for all the purposes to which the latter is applied. It has over this acid the great advantage of possessing an agreeable instead of a very offensive odor, and of not being an irritant or corrosive, and therefore of not causing pain. An objection has been made to it that in summer it tends to attract flies to the injured parts. Among surgeons who have expressed a favorable judgment of its antiseptic qualities is Mr. Spencer Wells, who in a series of *ovariotomy* operations gave it the preference over carbolic acid. He used a solution of 1 : 1000 for spray, irrigation, sponges, instruments, and all other antiseptic purposes. It has been employed to correct the *fetor* of suppurating *burns* and *gangrenous wounds* and *ulcers*. Indeed, it has been found to be an excellent anodyne for recent burns in a solution of 1 : 1000 of water. Where sloughs exist it causes them to separate more rapidly than usual, leaving more healthy granulations and a better cicatrix than after carbolic acid. A solution of 1 : 3000 was found an efficient lotion in a case of violent *stomatitis* and in seven cases of *diphtheria*, in which it was injected into the nostrils and throat. A similar solution atomized is of great benefit in *fetid bronchitis*. Its agreeable taste and smell adapt it especially to the last-named purposes. In obstetrical practice when the *lochia* are offensive, and in cases of fetid urine or vaginal *leucorrhœa*, and even when the discharge is due to *cancer of the uterus, vagina, or bladder*, not only is the fetor neutralized, but the inflamed and ulcerated tissues are favorably modified. It is a very efficient and agreeable *deodorizer* for the hands of surgeons and obstetricians. In lesions of the vagina and other accessible parts a lotion should be used several times a day, and cotton saturated with thymolized glycerin may be left in contact with the diseased structure. For these different purposes the solution should vary in strength from 1 : 1000 to 1 : 4000 (Seyferth).

Injected into dead bodies, it preserves them from decomposition; applied pure to *warts*,

it causes them to shrivel and disappear. In *skin diseases* it has been found useful in the same cases for which tar has so long proved to be the best topical remedy—that is to say, in *psoriasis* and chronic *eczema*, but especially in the former—and it has the advantage over tar of not staining the bed- and body-clothing. It is recommended to apply it in an ointment consisting of 1 ounce of soft paraffin and from 5 to 30 grains (Gm. 0.30–2) of thymol, or in a lotion consisting of thymol 5 grains (Gm. 0.30), rectified spirit and glycerin each 1 ounce, water to make 8 ounces. In “ringworm” Morris advises as a lotion, thymol 5ss; chloroform 3ij; olive oil 5vj (*Practitioner*, xxvi. 362).

Thymol has not been much administered internally except by inhalation, but it has been thought to act advantageously in doses of from 3 to 5 drops (Gm. 0.15–0.25) of a 1 per cent. solution in cases of *vesical catarrh* and of *infantile diarrhœa*.

As a substitute for the antiseptic surgical dressing prepared with carbolic acid a solution is recommended as follows: Thymol 1 Gm., alcohol 10, glycerin 30, water 1000 (Gm. This solution has no corrosive action on instruments immersed in it; it causes, however, a lively sensation of burning, accompanied with redness of the skin, but not with anæsthesia, and it does not produce desquamation of the epidermis. Neither does it, like carbolic acid, give rise to constitutional symptoms, nor occasion as much discharge from wounds as carbolic acid does. As a substitute for carbolic acid in the antiseptic method of dressing wounds, its effects are reported to be excellent. After forty-one out of fifty-nine operations the secretion was serous in only eight and purulent in two; in the remainder there was absolutely no secretion. Many of these operations involved large surfaces or were for diseased joints, etc. According to Ranke, the results obtained with thymol (antiseptically considered) are as good as those with carbolic acid, while the former presents these advantages: that the secretion of wounds treated by it is much less, and their rate of healing much quicker. Moreover, it produces no bad effects upon the system at large, and does not irritate the parts to which it is applied in solution (*Medical Times and Gazette*, March, 1878).

OLEUM TIGLII, U. S.—CROTON OIL.

Oleum crotonis, Br., P. G.—*Huile de croton*, *Huile de graines de tilly*, Fr.; *Crotonöl*, G.

The fixed oil expressed from the seeds of *Croton Tiglium*, Linné, s. *Tiglium officinale*, Klotzsch. Woodville, vol. v.; Bentley and Trimen, *Med. Plants*, 239.

Nat. Ord.—Euphorbiaceæ.

Origin.—This species of croton is common in the wild state as well as cultivated throughout Hindostan and some of the East Indian and Philippine islands, and has been introduced into Japan and other countries. It is about 15 or 20 feet (4.5–6 M.) high, has alternate petiolate, acutely-ovate, serrulate leaves, and terminal racemes of unisexual flowers. The fruit is a tricoecous capsule, nearly $\frac{3}{4}$ inch (18 Mm.) long, each cell containing a single seed.

SEMEN (GRANA) TIGLII, SEMEN CROTONIS.—Croton-seeds, *E.*; Graines de tilly, Petits pignons d'Inde, Fr.; Granatill, Purgirkörner, G.

The seeds are about $\frac{1}{2}$ inch (12 Mm.) long, oblong, flattened upon the ventral surface, and marked longitudinally by the slightly elevated raphe. The dorsal surface is rounded. Externally the seed is of a gray-brown color, mostly more or less mottled, or of a nearly uniform blackish color where the outer coat has been removed. The testa is brittle, and encloses an oily albumen of the shape of the seed and the thin foliaceous embryo. The seed is without odor, and has an oily afterward very acrid taste.

Preparation.—The fixed oil is obtained in India and in Great Britain by subjecting the seeds to pressure. The yield is between 50 and 60, or, according to other statements, between 30 and 40, per cent; the former amount probably refers to the kernels, the latter to the seeds, which are stated to yield from 33 to 36 per cent. of their weight of integuments. 5100 pounds of croton oil were imported into the United States in 1878, and in 1883 only 308 pounds.

Properties.—Croton oil from India is of a pale-yellow color; that made in England is of a more or less deep reddish-brown hue, the darker color being probably due to the greater age of the seed and to the higher temperature at which the oil is expressed. It has a slight, peculiar, somewhat rancid odor, and a taste which is at first mild, but afterward acrid and burning. Its reaction to test-paper is distinctly acid, and its consistence rather viscid. It is somewhat fluorescent, dissolves freely in ether, chloroform, carbon disulphide, and fixed and volatile oils, and varies in its behavior to alcohol, according to Warrington (1865) being more soluble in that menstruum when old and partly oxidized;

fresh croton oil requires about 60 parts of alcohol for solution. II. Senier (1878) ascertained that alcohol dissolves from freshly-expressed croton oil 20 per cent., and from

FIG. 201.

Croton-seed: lateral and ventral view, and longitudinal section, showing embryo.

such over three years old 60 per cent., and in 1883 showed that the portion insoluble in alcohol contains the purgative principle, while the vesicating principle is soluble in alcohol. The oil has a specific gravity of about .942, which increases with age to about .955. At a low temperature it separates white granules of fatty acid and congeals at about -16°C . (3.2°F). Exposed to air, it becomes more viscid, perhaps from the separation of fatty acids, and not from the presence of a drying oil, although, like the latter it is not solidified when in contact with nitrous acid.

Composition.—The fats present in croton oil are glycerides of stearic, palmitic, myristic, and lauric acids, and of several volatile acids of the same series, like acetic, butyric, and valerianic acid; also the volatile *tiglinic acid*, $\text{C}_5\text{H}_8\text{O}_2$, which was recognized by Geuther and Frölich (1870), but had previously been observed by Schlippe (1858), who considered it to be identical with angelic acid. However, it melts at 64°C . (147°F), boils at 198.5°C . (389.3°F), and is identical with Frankland and Duppá's methylcrotonic acid. In the fraction boiling above the temperature named, capronic, cmanthyllic, or similar acids are probably present. They did not succeed in obtaining from croton oil an acid having the composition of Schlippe's *crotonic acid*, $\text{C}_4\text{H}_6\text{O}_2$. E. Schmitt (1879) corroborated these statements, and found among the volatile acids also formic acid. Schlippe's *crotonal*, $\text{C}_{18}\text{H}_{32}\text{O}_4$, has likewise not been obtained by other chemists; it was stated to be a yellowish viscid mass of a faint odor, and to be the rubefacient principle of croton oil. The drastic rubefacient properties, according to Buchheim (1873), reside in *crotonoleic acid*, which is present in the free state and as glyceride, and which seems to be related to ricinoleic acid, since, like the latter, it yields with nitric acid cmanthic acid, and on the distillation of its sodium salt gives cmanthol. But H. Senier has shown (1883) that the oil may retain its purgative action and may be deprived of vesicating properties (see above); the latter do not reside in the free acids present, nor in any basic constituent, but exist in a fat which is not readily saponifiable, and yields an acid of low melting-point and forming a lead salt soluble in ether.

Tests.—The process of Schlippe for preparing crotonol afforded us (1860) the means of detecting croton oil in other oils. The suspected oil is agitated with a solution of soda or potassa in dilute alcohol; the alcoholic liquid is separated, neutralized with hydrochloric acid, and a little of the oily layer separating is applied upon the arm, when in a few hours redness and the peculiar pustular eruption will appear. Should the quantity be small, the liquid is acidulated, agitated with ether, the ether evaporated, and the residue applied. Senier's observations explain the rationale of this process. The *Br. P.* requires croton oil to be entirely soluble in alcohol.

Allied Oils.—(See *CYCLES*, page 532.) The oil obtained by bisulphide of carbon from the seeds of *Euphorbia Lathyris*, *Linne*, has been recommended by Zander (1878) as a cheaper substitute for croton oil.

Off. Prep.—*Linimentum crotonis*, *Br.*

History.—Our knowledge of this medicine was derived from the Orientals through the Arabians, it having been used from time immemorial in Hindostan as a purgative and external irritant. It was introduced into Europe in 1820.

Physiological Action.—*On Animals:* The seeds, reduced to a paste and administered to dogs, produce painful purging, and after death evidences of violent inflammation of the mucous membrane of the stomach and intestine are discovered. In Java they are employed for killing fish. The oil given to dogs acts rapidly as an emeto-cathartic. When injected into a vein by one experimenter, 5 drops caused vomiting and purging, and death in 2 hours. The stomach and intestine were inflamed. The same experiment performed by others indicated an action of the oil in depressing the heart and the nervous system, but gave no evidence of irritation of the alimentary canal before or after death.

On Man: A croton-seed, when chewed, has a sweet and oily taste, followed by a bitter and acrid savor and salivation; nausea, eructation, flatulent distension of the abdomen, colic, and diarrhœa follow. A single seed is reported in one case to have proved fatal. The oil, in the dose of 1 drop, occasions more or less of an acrid and burning sensation in the fauces and œsophagus, a sense of warmth in the stomach, nausea, and sometimes vomiting. In an hour or two some gurgling or slight colic is perceived in the bowels, followed somewhat suddenly by a watery stool with tenesmus, and heat about the anus.

Within 24 hours eight or ten more stools follow, and there is but little general disturbance of the economy, except considerable weakness. Sometimes, instead of producing evacuations, the oil causes epigastric uneasiness and oppression, palpitation of the heart, headache, feverishness, perspiration, and sleep. It would appear that the acrid principle of the oil is not the sole cause of its cathartic operation, for even after being thoroughly washed with alcohol and rendered mild to the taste, as well as incapable of pustulating the skin, it is still strongly purgative. When given in enema in the dose of 3 or 4 drops, croton oil operates purgatively.

In excessive doses this oil may act as a violent and fatal poison, producing severe pain and general collapse, without loss of consciousness. After death no lesion of the stomach or intestines may be found. There are, on the other hand, cases in which recovery has followed excessive doses. For example, a girl six years old having swallowed about 46 grains of croton oil mixed with milk and coffee, and when the stomach was empty, suffered acute gastric pain and violent and profuse vomiting. The emesis probably saved her life. In another instance a woman 2 days after confinement took "over 2 teaspoonfuls of croton oil." No vomiting ensued, but violent purgation and collapse. Recovery took place, but the woman shed her finger- and toe-nails (*Richmond and Louisville Med. Jour.*, xiii. p. 651). In the case of an habitual drunkard who swallowed "a little less than 2 drachms of croton oil in a glass of whiskey" there was active vomiting, but no purgation, and some hours later the man was found dead. On examination the whole visceral peritoneum was of an intense dark-red color and the gastro-intestinal mucous membrane was of a like hue and almost disorganized (*Amer. Jour. of Med. Sci.*, Apr. 1874, p. 416). A woman in the seventh month of pregnancy took about 2 drachms of croton oil in the course of 2 hours. She too was collapsed after violent purging (without vomiting), and fell into labor; her child was born without assistance, and the woman recovered (*Phila. Med. Times*, xi. 370).

Externally, croton oil rubbed upon the skin occasionally produces purgation. Its ordinary effects are, however, local. In general, it brings out, after a few hours, an eruption of minute red pimples, which are always more numerous in proportion to the vascularity and delicacy of the skin, and are gradually converted into pustules, generally of an acuminated or rounded shape, but some are flattened and umbilicated; many are confluent. A red areola surrounds each of them, and they cause severe burning and itching. They augment for three or four days, and then remain stationary. Some break and others wither away. If numerous, they may form thick and extensive crusts. These are thrown off between the sixth and the twelfth day, and leave no cicatrix behind them. The endermic inoculation of the oil causes small but painful abscesses.

Uses.—In obstinate constipation of the bowels, and when there exists no contraindication arising from inflammation or structural alteration, croton oil is an appropriate purgative. But the observance of these conditions is very important. The oil is most appropriate when bulky doses are objectionable, and when the patient resists the administration of more usual cathartics. Of the former sort are cases of intestinal obstruction from accumulated feces produced by simple torpor of the bowels, diseases of the nervous centres, the poison of lead, etc. Of the latter are the frequent instances of a refusal to take medicine among children and insane persons, but the oil should rarely be given to children. It is customary to administer it to the insane in milk broth—a most vicious and inhuman practice, since it arouses suspicion or an aversion to articles upon which the patients' lives may depend. In *bad colic* it has, to a great extent, superseded other purgatives. It should be given in the dose of 1 drop (Gm. 0.06) daily or twice a day, and need not interfere with the simultaneous use of narcotics internally and externally. Like other active purgatives, it has been employed to expel *tæniæ*, and it is even said to have done so when mixed with olive oil and rubbed upon the abdomen; but many surer remedies for these parasites exist. In like manner, it has been given successfully as a drastic purgative in different forms of *dropsy*, but it is unnecessarily harsh. Its irritant substitutive action has been invoked in *dysentery*, but safer and less harsh remedies are to be preferred. In *apoplexy* it is customary to employ it for its depletory revulsive action and for the convenience of its administration during the stupor of the attack. If the attack is one of congestive apoplexy, denoted by turgor of the face, laboring heart and pulse, etc., purgation is generally indicated, but in an opposite condition it is contraindicated.

Externally, croton oil has been used to relieve cerebral symptoms following the suppression of a cutaneous eruption and other causes; and in the various forms of *meningitis* it is the most efficient mode of counter-irritation of the scalp. It is less painful than

tartar-emetic pustulation, and more permanent in its action than cantharides. It is an efficient counter-irritant in spinal *neuralgia*, but is objectionable on account of the difficulty of restricting its action to a definite area. It has been more successful in *sciatica* than in any other form of neuralgia. For this affection it has also been recommended internally, but upon less substantial grounds. It has been applied locally in chronic articular *rheumatism*, and is undoubtedly one of the best of the topical remedies for the disease. Its moderate but steady counter-irritation renders it peculiarly valuable in cases of *chronic bronchitis* and *chronic laryngitis*.

Tinea tonsurans, or ringworm of the scalp, has been treated successfully by croton oil, which is applied pure until the characteristic eruption appears, when a poultice is used to soften and remove the crusts of the original disease and those produced by the oil. It is recommended, when a large portion of the scalp is involved, that a small portion only should be treated at a time, on account of the irritation and fever which usually are excited. The conditions favorable to the success of this treatment are, however, far from definite.

Administration.—Croton oil may be given in emulsion or mixed with some other oil or in pill. Of these forms the last is to be preferred. The *dose* is from $\frac{1}{4}$ drop to 2 drops (Gm. 0.016–0.13). The following is a safe and convenient prescription: Add to 2 drops (Gm. 0.12) of croton oil enough alcohol to dissolve them, and then bread-crumbs in sufficient quantity. Make from four to eight pills, and direct one to be taken every hour or two. Externally, the oil may be applied by means of a feather, brush, or other convenient instrument, and friction made with a rag until the skin becomes dry. It may be used pure or mixed with castor oil, olive oil, soap liniment, alcohol, or ether; or a piece of muslin somewhat smaller than one of adhesive plaster may be attached to the latter, and moistened with the oil before being applied to the skin. A mixture of 1 part of croton oil with 7 of oil of turpentine is more rapid in its action than the oil alone.

As antidotes to the *poisonous* effects of this oil, milk, olive oil, mucilage, gelatin soup, etc. may be given to envelop the acrid substance, and if it cause a tendency to collapse, opium and alcoholic liquids and warm stimulating baths should be employed.

OLEUM VALERIANÆ, U. S.—OIL OF VALERIAN.

Essence de valériane, Fr.; *Baldrianöl*, G.

The volatile oil distilled from the root of *Valeriana officinalis*, *Linné*.

Nat. Ord.—Valerianaceæ.

Preparation.—The volatile oil is obtained by distilling the crushed root with water or steam. The yield varies between $\frac{1}{2}$ and 2 per cent., and is largest from valerian grown in dry localities. 5 pounds of oil of valerian were imported into the United States in 1876, and 167 pounds in 1878.

Properties.—When recently distilled from fresh root the oil of valerian is of a greenish or yellowish color, limpid, of a mild odor, and of a neutral reaction. On exposure to air it becomes deeper yellow and brown, viscid, and acquires a strong odor and an acid reaction. Old roots yield at once a dark, acid, and strongly odorous oil. Its taste is aromatic, somewhat camphoraceous, not burning; its density is near 0.94. It is readily soluble in alcohol, does not fulminate with iodine, and becomes purplish-black with ethereal solution of bromine, dark-red with sulphuric acid, purplish-red with hydrochloric acid gas, and blue with nitric acid.

Composition.—The latest investigation is by G. Bruylants (1878), who ascertained some new facts. The hydrocarbon, $C_{10}H_{16}$, was named *borneene* by Gerhardt (1841) and *valerene* by Pierlot (1859). The *valerol* of the latter differed from Gerhardt's valerol, $C_6H_{10}O$, which he believed to become oxidized in contact with air to *valerianic acid*, carbonic acid being given off at the same time. Bruylants explains the generation of valerianic acid in old oil of valerian from the decomposition of $C_{10}H_{17}C_5H_9O_2$, which is the valerianic ether of borneol; besides this one, it contains the corresponding ethers of formic and acetic acids, the alcohol *borneol*, $C_{10}H_{18}O$, and its ether, $(C_{10}H_{17})_2O$. Gerhardt assumed the production of borneol from the hydration of borneene. (See OLEUM CAMPHORÆ, page 367.)

Medical Action and Uses.—In experiments upon animals with poisonous doses of this oil it appeared to blunt the reflex excitability after having primarily stimulated it, and to produce a similar effect when the same function was previously excited by strychnia. It has been used with advantage in *hysteria*, *chorea*, and even in *epilepsy*;

but it is most efficient in the first-named disease, and in the various functional nervous derangements which, without constituting hysteria, are nevertheless hysterical. It may be prescribed in doses of 1 drop (Gm. 0.06) and upward in pill, emulsion, or alcoholic solution.

OLIBANUM.—FRANKINCENSE.

Gummi resina olibanum, Thus.—Oliban, *Encens*, Fr.; *Weihrauch*, G.

From *Boswellia Carterii*, *Birdwood*, and other species of *Boswellia*. *Trans. Linn. Soc.*, xxvii. t. 29, 30, 31; Bentley and Trimen, *Med. Plants*, 58.

Nat. Ord.—Burseraceæ.

Origin.—The genus *Boswellia* is confined to India, Southern Arabia, and Eastern Africa. It comprises trees with imparipinnate leaves, serrate leaflets, small, racemose, decandrous flowers, and three-celled drupaceous capsules containing three seeds. The different species are still imperfectly known. *B. Carterii* may possibly be a polymorphous species, or several forms at present regarded as mere varieties may be distinct species, which grow only in two limited districts in South-eastern Arabia and in the Somali country of Eastern Africa. *B. papyrifera*, *Richard*, indigenous to Nubia and Abyssinia, yields a similar product, which, however, is not collected. *B. thurifera*, *Colebrook* (*B. serrata* and *B. glabra*, *Roseburgh*), affords a soft odorous resin which is used in India as incense. The fragrant resin of *B. Frereana*, *Birdwood*, of the Somali country, is used in the East as a masticatory.

Collection.—The collection of olibanum in the Somali country was described by Cruttenden (1846), and in Arabia by Carter (1847), who had visited these countries three years previously. Deep incisions are made from which a milk-white exudation flows, which gradually hardens, and is then collected. Olibanum enters commerce by way of Bombay. Over 80,000 pounds were imported into the United States in 1882.

Description.—Olibanum consists of roundish, oblong, or irregular-shaped separate tears. These vary in diameter between $\frac{1}{8}$ and $\frac{1}{2}$ inch (3–12 Mm.) or more, and are nearly colorless, pale-yellowish, or of a reddish hue, and covered with a whitish powder, resulting from the attrition of the pieces. When broken they exhibit a flat scarcely conchoidal fracture and a waxy lustre. Olibanum has a balsamic somewhat terebinthinate odor, softens between the teeth, and has a balsamic and slightly bitter taste. Triturated with water, it yields a white emulsion; alcohol dissolves the greater part of it. When heated it becomes soft and burns, diffusing an aromatic odor.

Olibanum of inferior quality is more deeply colored, often opaque, and more or less mixed with fragments of bark and other impurities.

Constituents.—By distillation with water a volatile oil is obtained varying in quantity from 4 (Stenhouse, 1840) to 7 per cent. Kurbatow (1871) found it to consist of *olibene*, $C_{10}H_{16}$, and an oxygenated portion boiling above $175^{\circ} C.$ ($347^{\circ} F.$). Olibene is the chief constituent of the oil, boils at about $157^{\circ} C.$ ($314.6^{\circ} F.$), has a turpentine-like odor, and yields with hydrochloric acid gas a crystalline compound. The resin amounts to 56 (Braconnot, 1808), or as much as 72, per cent. (Kurbatow), and, according to Ilasiwetz (1867), has the composition $C_{20}H_{30}O_3$. The gummy matter contained in olibanum was found by Hekmeijer (1858) to agree in behavior with gum-arabic.

Pharmaceutical Uses.—Olibanum is a constituent of most *fumigating powders*, for which there are a large number of formulas in existence; they contain also benzoin, storax, mastic, amber, cascarilla, orris-root, santal-wood, or other odoriferous drugs, which are reduced to a coarse powder, and when used thrown upon a heated surface. *Fumigating pastilles* are made of a similar composition, and should contain about 40 per cent. of ligneous material or charcoal and from 5 to 8 per cent. of potassium nitrate; the finely-powdered ingredients are well mixed, formed into a mass with mucilage of tragacanth, and then moulded into the desired shape.

Medical Action and Uses.—Although no longer officinal in either the United States or the British Pharmacopœia, olibanum is one of the most ancient, as it once was one of the most valued, of medicines. It was the frankincense of which so much is said in the Old Testament, and which was used by the Egyptians in embalming; it is spoken of in the Hippocratic writings as an expectorant in bronchial catarrh and in infantile asthma, as useful in expelling the lochia and promoting menstruation, as an ingredient of injections for leucorrhœa, and of ointments for various ulcers, including those caused by burns. Later it was applied in ointments to *chillblains*, *cutaneous eruptions*, and *inflammations of the eyes*. More recently it was an ingredient of various stimulating plasters,

and its fragrant fumes were used to conceal *unpleasant smells*. The *dose* is stated to be from 30 to 60 grains (Gm. 2-4) given in emulsion.

OPIUM, *U. S.*, *Br.*, *P. G.*—OPIUM.

Meconium, Succus thebaicus.—Opium, *E.*, *Fr.*, *G.*

The concrete milky exudation obtained in Asia Minor from the unripe capsules of *Papaver somniferum*, *Linné*, by incision and spontaneous evaporation. Bentley and Trimen, *Med. Plants*, 18.

Official Forms of Opium.—OPIUM PULVIS, *U. S.*—Powdered opium, *E.*; Poudre d'opium, *Fr.*; Opiumpulver, *G.*—Opium dried at a temperature not exceeding 85° C. (185° F.), (60° C. = 140° F. *P. G.*), and reduced to a moderately fine (No. 50) powder. Powdered opium, for pharmaceutical or medicinal uses, should contain not less than 12 nor more than 16 per cent. (not less than 10 per cent. *P. G.*) of morphine when assayed by the process given under OPIUM. Any powdered opium of a higher percentage may be brought within these limits by admixture with powdered opium of a lower percentage in proper proportions.—*U. S.*

OPIUM, *U. S.*, *Br.*, *F. Cod.*, *P. G.* Opium in its normal moist condition should yield not less than 9 per cent. (after drying, 9.5 to 10.5 per cent. *Br.*) of morphine.—*U. S.*

OPIUM DENARCOTISATUM, *U. S.*, OPIUM DENARCOTINATUM.—Denarcotized opium, *E.*; Opium denarcotiné, *Fr.*; Denarcotinirtes Opium, *G.*—Denarcotized opium, when assayed by the process mentioned below, should yield 14 per cent. of morphine.—*U. S.*

Origin and Production.—The poppy-capsule, which is described elsewhere (see PAPAVER), contains under the epidermis a large number of laticiferous vessels which are variously branched and interlaced, and in the unripe state of the fruit are filled with a white milk-juice, which escapes when an incision is made. For its successful cultivation the poppy requires a deep, rich, and well-manured soil, and considerable attention until the plant has sufficiently matured to permit of the collection of the milk-juice. A few days after the petals have fallen the green capsule is scarified, with the precaution of not cutting entirely through the capsular integuments, as the juice would then flow into the capsule and be lost. In Asia Minor and Egypt one or two incisions are made transversely near the middle of the capsule, so as to run spirally around it. In India three or four vertical incisions are made from the base to the apex and on different sides of the capsule, the instrument used for the purpose, called *mshtur*, being a three- or four-bladed knife protected by means of twine, so as to prevent the blades from penetrating too deeply. The scarifications being made in the afternoon, the milk-juice is ready for collection the next morning, when its color will have changed from white to brown. The juice is then carefully scraped off with a knife, which is moistened from time to time with water, or in Asia Minor by drawing it through the mouth; in Persia oil is used to prevent the juice from adhering to the scraper.

In Asia Minor the juice is transferred to a poppy-leaf and formed into cakes varying greatly in size—from a few ounces to 2 pounds or more in weight. These soft cakes are subsequently often mixed together for the purpose of obtaining larger cakes, which are surrounded by one or two wilted poppy-leaves, afterward packed with a considerable quantity of the dry fruits of a species of *Rumex*, thus preventing the cakes from adhering to one another, and then transported to Smyrna or Constantinople, whence the European and American markets are chiefly supplied.

In *Egypt* opium is collected and prepared for the market in a manner similar to that just described. The production in that country at one time considerably declined, but has increased since Gastinel Bey (1865) proved that opium equal in quality to that of Asia Minor could be gathered by bestowing sufficient care upon the cultivation of the plant.

The juice gathered in *India* is usually quite soft in consequence of dew, and after collection separates a dark-colored fluid called *passawa*, which, together with the washings of vessels and some opium, is evaporated to a thick liquid called *lewa*, and this is employed in agglutinating the poppy-petals together, so as to form an envelope, and, after drying, a rather hard shell for the protection of the opium. The opium, which is moulded into spherical balls, requires much attention until it has been sufficiently dried for preservation. Each ball weighs a little over 4 pounds; forty of these are packed in separate compartments in a case, and are mostly exported to China. In the commerce of India this is known as *provision opium*; for home consumption the juice is evaporated by the heat of the sun and formed into square or sometimes circular cakes, which are wrapped in oiled paper.

Persian opium is formed into cylindrical sticks about 6 inches long, each of which is wrapped in paper, or into cones or small balls about 1½ inches in diameter, the wrapper of which is sometimes marked with Chinese characters. Since 1856, *Persian* opium has been sent to Constantinople, and there worked over so as to resemble that of *Asia Minor*. At the present time it is frequently seen in European commerce, and it is imported in considerable quantity into the United States to be used in the manufacture of morphine. It often comes in cakes weighing 1 or 1½ pounds, which are oily and always packed in *poppy trash*—i. e. the dried stalks and capsules ground into coarse powder.

China produces a large quantity of opium, all of which is consumed in that country: in addition it consumes notable quantities imported from *Persia*, as well as by far the largest portion of the opium which is exported from *India*. The samples which we have seen were flattish-globular in shape and wrapped in white paper; one specimen was oily, though less so than *Persian* opium, and another, to judge from its black-brown color, was prepared by the aid of artificial heat, though free from empyreuma.

In *Japan* the milk-juice is obtained by the longitudinal scarification of the poppy-capsules, and the opium is formed into flat cakes which are wrapped in paper.

Numerous experiments have been made in *Europe*, and opium of excellent quality has been obtained as far north as *Sweden*; but European opium is not an article of commerce, and its production appears to very limited. It is stated that Auberger calls the opium raised by him in France *affium*, and that it is formed from the agglomeration of tears exuded from the incisions and entirely free from foreign admixture.

In *Algeria* opium has been produced since 1828—in limited quantities, however, and insufficient to be of any commercial importance. Rohlf's (1866) found an extensive culture of opium in the oasis of Tuat in the northern part of the great African desert.

Opium has also been raised experimentally in *Victoria, Australia*, and was stated by Mr. Bosisto (1876) to be of good quality.

About the year 1812 opium of fair quality was produced in the *United States*, chiefly, if not exclusively, in *New England*. After the close of the war the cultivation had to be abandoned—as it appears, mainly because the product became unsalable in consequence of extensive adulterations; more recently, however, opium-culture again attracted attention, more particularly during the late Civil War, when the drug was successfully produced in *Virginia*, *Tennessee*, and *South Carolina*. Prof. Porcher (*Resources of the Southern Fields and Forests*, p. 26) states that in the climate of *South Carolina* and *Georgia* the poppy should be planted in September; the plants are not killed during the winter; they thrive in the early spring, and the capsules are ready for incision in May. Several attempts made to obtain the poppy by planting in April and May failed, the seeds not coming up. A "garden square" yielded him 330 grains of very dry opium of excellent quality.

In *Asia Minor* the poppy-seed is sown at intervals from November to March. By following this course failure from frosts or other causes is guarded against, and the maturing of the poppy-heads is extended over a certain length of time. Since by the circular incisions made there all or nearly all the laticiferous vessels are cut, a second scarification is generally unprofitable, while an additional quantity of milky juice is usually obtained on repeating the vertical incisions after a day or two.

The variety of *poppy* cultivated in *Asia Minor* is the black, which has usually purple flowers and black, though occasionally white, seeds. This variety is that also which, in the experience of Auberger in France and of Behr and Biltz in Germany, yields opium richer in morphine than that produced from the white-flowering and white-seeded poppy. The latter is, however, by some persons considered more advantageous for collection, and appears to be the only kind cultivated in *Egypt*, *Persia*, *India*, *China*, and *Japan*.

The importation of opium by the United States has of late years been steadily increasing; it amounted to 135,305 pounds in 1867, and rose to 385,060 pounds in 1881. Of opium prepared for smoking, 12,603 pounds entered the United States in 1870, and 298,153 pounds in 1883.

Description.—Opium is in subglobular, usually more or less flattened, irregular cakes, which are externally of a chestnut-brown or somewhat darker color, and bear on the surface the impressions of the veins of the poppy-leaf in which they had been enveloped; fragments of the leaf and some fruits of a *Rumex* are generally adhering to the surface. The whole mass is usually plastic, but on keeping a harder external crust is formed, while the interior portion retains its moist condition for a long time. When broken, some tears are usually observed in the interior, together with fragments of vegetable tissue which have been detached in scraping off the milk-juice. The cakes weigh from about 4 ounces to 2 pounds. The odor of opium is heavy and narcotic, its taste

disagreeable and bitter. Examined under the microscope, some needle-shaped crystals are observed, but most of it consists of an amorphous or granular mass, aside from the vegetable tissue present. The crystals are best observed after the dry opium has been well moistened with benzol.

Smyna, Turkey, or Constantinople opium is the only variety recognized by the different pharmacopœias and met with in American commerce. It has been stated above that Persian opium is often imported for the manufacture of the alkaloids. It is oily from the manner in which it has been collected. Its other distinctive characters and those of East Indian opium have already been briefly described. Both varieties contain usually a larger number of crystals than Turkey opium, and these crystals may not unfrequently be seen with the naked eye or by the aid of a lens.

Adulterations.—The principal admixtures observed by us in Turkey opium were pebbles, shot, and lead balls introduced into the interior of the cakes. When present these admixtures generally amount to several ounces, but are only occasionally seen. Of greater importance appears to be the introduction of excessive quantities of vegetable tissue during the collection of the juice, but it is impossible to estimate its quantity or state its allowable limits. Coarse adulterations, such as the aqueous extract of the poppy-plant and of the herb *Glaucium luteum*—which, according to Landerer, is sometimes made in Turkey—are rarely, if ever, seen in the imported opium, and are readily detected by the darker color and the hygroscopic nature of the product, and by the uninterrupted streak which it leaves on being drawn over paper, while good opium makes an interrupted mark. Such partly factitious opium, or fraudulent substitution of an extract having a narcotic odor, for opium said to have been of American origin, was noticed by Procter (1869) and Ebert (1873). Various kinds of resinous, saccharine, mucilaginous, and amylaceous substances, ashes, clay, gypsum, litharge, and sand, have been employed for like purposes, and occasionally opium has been met with in the market which contained so little morphine and other alkaloids as to lead to the inference that these principles had been extracted. Another impurity is an excessive amount of moisture. Squibb (1860) estimated the average loss in drying to be 19.5 or 20 per cent., and in drying and powdering 20 to 21 per cent. From a record of nearly 12,000 pounds of opium, nearly the whole of which was directly obtained from importers, we find the average loss to have been 21.2 per cent.: in some exceptional cases as high as 28 or as low as 15 per cent. Bengal provision opium contains 30 per cent. of moisture.

Examination.—Hager suggested the following course for determining the presence of adulterations: The sample is dried and powdered, and 25 grains of the powder are triturated with $\frac{1}{2}$ ounce of boiling water; the formation of a stiff paste or mucilaginous liquid would indicate the presence of starch, flour, gum, or salep. 2 ounces of water are added, and the liquid filtered; the filtrate should be of a wine-yellow color, indicating the absence of liquorice or other aqueous extracts, which would impart to the filtrate a brown color; the liquid should likewise have an acid reaction, otherwise the admixture of chalk, litharge, or ashes may be inferred. On evaporating the filtrate to 1 ounce, ferrocyanide of potassium or the addition of twice its bulk of alcohol should not cause any precipitate; the former test would indicate the presence of salts of heavy metals; the latter an adulteration with gum or certain salts. The insoluble residue of opium left on the filter after washing and drying should weigh between 10 and 11½ grains; should it weigh more, sand, clay, or other insoluble substances may be present, and in case it weighs less, sugar, gum, or other soluble impurities are indicated. On agitating powdered opium with chloroform the mineral impurities and starch settle to the bottom, and the latter acquires a blue color on the addition of a little iodine. Mineral impurities are likewise indicated by the amount of ash left, which for genuine powdered opium is about 6 per cent., varying, however, between 4 and 8 per cent. The U. S. Pharmacopœia directs the estimation of the extract prepared with cold water from 100 parts of opium previously dried at 105° C. (221° F.); when evaporated to dryness the extract should weigh between 55 and 60 parts.

Constituents.—Opium is entirely free from starch and tannin. Among the principles ordinarily found in plants the following have been observed in opium: An odorous principle soluble in ether, benzol, and petroleum benzin; glucose, gum, pectin, a compound resembling caoutchouc, wax, fat, a small amount of resin, coloring matter, and that indefinite substance usually designated as extractive. The mineral constituents average 6 per cent., and 55 or 60 per cent. of dry opium is soluble in water, but the pure milk-juice, entirely free from vegetable tissue, yields a larger percentage to water.

The most important as well as the most interesting constituents of opium, however, are

the alkaloids; in fact, the first vegetable alkaloid discovered was obtained from opium. In 1816, after a patient investigation extending over 11 years, Sertürner, apothecary at Eimbeck in Northern Germany, announced the discovery of *morphium*. He recognized this principle as a salifiable base, in some respects related to ammonia. A crystalline powder, probably morphine or containing it, was obtained by Ludwig as early as 1688, and was named *magisterium opii*; and in 1803, Derosne obtained this principle by precipitating the aqueous infusion of opium with ammonia, but regarded it as identical with his *salt of opium* (narcotine), which crystallized from the concentrated infusion. Seguin (1804) had likewise observed it. Since Sertürner's discovery a large number of alkaloids have been isolated from opium, which, arranged in the order in which their isolation was announced, are as follows:

1. NARCOTINE, $C_{22}H_{23}NO_7$, was discovered by Derosne (1803), but its basic nature was first shown by Robiquet (1817). It may be extracted with ether from the precipitate produced by ammonia in the aqueous infusion of opium, and from the insoluble residue of the latter by exhausting it with hot acetic acid. It crystallizes in colorless shining rhombic prisms or white needles, which are tasteless and dissolve at about $15^{\circ} C.$ ($59^{\circ} F.$) in 100 parts of 85 per cent. alcohol, 33 parts of absolute ether, 2.7 parts of chloroform, 310 parts of amyl alcohol, or in 22 parts of benzol. The alkaloid requires 7000 parts of boiling water for solution, is insoluble in cold dilute acetic acid, is a weak base, and yields mostly uncrystallizable salts, which have a bitter taste and an acid reaction. Chloroform dissolves the alkaloid from the aqueous solutions of its salts (Dragendorff). Its solution in cold sulphuric acid is colorless, but turns slowly to yellow, orange, and red; it gives a blood-red color with a mixture of sulphuric and nitric acids. The alkaloid melts at $176^{\circ} C.$ ($349^{\circ} F.$). When boiled for a long time with water or heated with nitric acid, it is decomposed into *meconin*, $C_{10}H_{10}O_4$, and *cotarnine*, $C_{12}H_{13}NO_3$, which is a stronger base, soluble in ammonia, fusible in boiling water, and, on being boiled with very dilute nitric acid, is converted into *cotarnic* and *apophyllic acids*, the latter containing nitrogen. On heating narcotine with binoxide of manganese and dilute sulphuric acid, cotarnine is obtained, and in addition thereto *opianic acid*, $C_{10}H_{10}O_5$, which crystallizes in needles and fuses at $140^{\circ} C.$ ($284^{\circ} F.$). When heated with hydrochloric or hydriodic acid, it parts with one, two, or three methyl groups (CH_3), and yields new bases. Wright and Beckett (1876) showed that it may be converted into *vanillin*. According to Wegscheider (1883), opianic acid, heated above its melting-point, yields an anhydride, $C_{20}H_{20}O_{10}$, which by moderate fusion with potassa is converted into meconin and *hemipianic acid*, $C_{10}H_{10}O_6$, and on treating the latter under pressure with HCl , isovanillic and protocathechuic acids are obtained.

2. MORPHINE, $C_{17}H_{19}NO_3$, discovered by Sertürner (1816), is described in another place (see page 990); also its derivative, *apomorphine* (page 220). On heating its hydrochlorate with silver nitrate to $60^{\circ} C.$ ($140^{\circ} F.$), *oxymorphine* or *pseudo-morphine* is formed (see below). In the presence of ammonia and air morphine is oxidized to *oxydimorphine*, $C_{34}H_{36}N_2O_6$, which is also obtained from morphine by the action of potassium permanganate, potassium ferriyanide, or nitrites (Broeckmann and Polstorff, 1880).

3. CODEINE, $C_{18}H_{21}NO_3$, was discovered by Robiquet (1832), and by Grimaux (1881) prepared from morphine by heating it with methyl iodide and soda; it is therefore *methyl-morphine*. (For description see page 481.) A number of interesting derivatives have been prepared from this alkaloid, which, however, with the exception of apomorphine, have not been medicinally employed. The melting-point of codeine is $155^{\circ} C.$ ($311^{\circ} F.$), as given by the German Pharmacopœia, not $150^{\circ} C.$, as determined by Robiquet (Hesse, 1883).

4. NARCEINE, or *narcia*, $C_{23}H_{29}NO_9$, discovered by Pelletier (1832), is in long quadrangular prisms or white silky needles, which have a slight bitter taste, melt at $145.2^{\circ} C.$ ($291.6^{\circ} F.$), are insoluble in ether, and are sparingly soluble in cold alcohol and water. Fröhde's reagent renders it brown-green, yellow, afterward reddish. Erdmann's test produces a deep-yellow, brown-yellow, and finally a deep-orange color. Iodine not used in excess produces a blue color, nitric acid a rapidly-fading yellow color. The blue color obtained by Pelletier on the addition to narceine of strong hydrochloric acid and a small portion of water is not observed with the pure alkaloid, according to Winckler, Anderson, and others. Narceine is a weak base, and yields crystallizable salts which are mostly not freely soluble in water or are decomposed by water, the hydrochlorate yielding a highly basic salt (Wright and Beckett, 1876).

5. PSEUDOMORPHINE, also called *phormine* and oxydimorphine, $C_{34}H_{36}N_2O_6$, was discovered by Pelletier and Thiboumery (1835), and is probably present in opium after

exposure to ammoniacal vapors. It is a derivative of morphine, and is readily formed by warming an aqueous solution of morphine nitrite to 60° C. (140° F.) and crystallizing from ammonia-water. Hesse (1883) gives to the alkaloid the formula $C_{17}H_{17}NO_3$, and states that it absorbs water on exposure. It is a fine crystalline powder, is insoluble in water, alcohol, ether, and chloroform; dissolves in acetic acid; yields with hydrochloric acid a salt sparingly soluble in cold water; and is colored red by nitric acid and blue by ferric chloride, in which behavior it resembles morphine.

6. THEBAINE, or *paramorphine*, $C_{19}H_{21}NO_3$, was discovered by Thiboumery (1835). It forms silvery scales or hard prisms; is soluble in ether, more freely soluble in alcohol, amyl alcohol, benzol, and chloroform, but nearly insoluble in water and alkalis. It is colored blood-red, afterward yellow, by sulphuric acid, yellow by nitric acid, orange-red by Erdmann's test, orange-yellow and finally colorless by Fröhde's reagent, and red-brown by chlorine-water and ammonia. The salts of thebaine crystallize readily. Diluted acids readily alter the alkaloid, yielding two amorphous isomeric bases, *thebaine* and *thebaine*, which are sparingly soluble in hot alcohol and insoluble in other simple solvents (Hesse).

7. PAPAVERINE, $C_{21}H_{21}NO_4$, discovered by Merck (1848), forms colorless needles or prisms, which are slightly soluble in cold ether and alcohol, but readily soluble in hot alcohol, amyl alcohol, chloroform, and benzol. It melts at 147° C. (296.6° F.). Nearly all its salts are sparingly soluble in cold water and dilute acids, and its solutions part with the alkaloid on being agitated with chloroform. Warm sulphuric acid colors it deep-purple or violet-blue. Fröhde's reagent renders it bright violet-blue, then blue, yellowish, and finally colorless.

8. RHÆADINE, $C_{21}H_{21}NO_6$, discovered by O. Hesse (1865), is in white tasteless prisms which are nearly insoluble in ether, alcohol, benzol, chloroform, water, and ammonia, and which yield with dilute acids tasteless and colorless solutions, acquiring an intense purple color on the addition of strong hydrochloric or sulphuric acid. Besides the coloring matter, an isomeric bitter, colorless base, *rhæagenine*, is formed in this reaction. The color produced by acids with Merck's *porphyrocin* (1837) depends on the presence of some rhæadine.

9. CRYPTOPINE, $C_{21}H_{23}NO_5$, was discovered by T. and H. Smith (1867). It crystallizes in minute prisms, is sparingly soluble in water, ether, benzol, and cold alcohol, dissolves in potassa and chloroform, and forms bitter salts, which have a pungently cooling taste, and when dissolved in hot water usually produce a jelly-like mass, which is gradually changed to crystals. Sulphuric acid colors it yellow, soon turning violet-color, but in the presence of minute traces of ferric salt or of chlorine a dark violet-blue color is at once produced, which on warming turns dingy green.

10. OXYNARCOTINE, $C_{22}H_{23}NO_6$, was isolated from the mother-liquors of narcine by Wright and Beckett (1876). It dissolves in alkaline liquids, but is nearly insoluble in benzol, chloroform, and hot alcohol and water. Like narcine and narcotine, it yields *hemipinic acid*.

11. GNOSCOPINE, $C_{31}H_{36}N_2O_{11}$, was found by T. and H. Smith (1878) in the mother-liquors of narcine. It forms thin needles of a woolly appearance, melts with decomposition at 233° C., is soluble in chloroform and carbon disulphide, slightly soluble in benzol, and is insoluble in petroleum and in fusel oil. Sulphuric acid dissolves it with a yellowish color, becoming carmine-red with a trace of nitric acid.

The following alkaloids were discovered by O. Hesse (1870 and 1871), and may be prepared from the mother-liquors left in the preparation of morphine by Gregory's method:

12. LANTHOPINE, $C_{23}H_{23}NO_4$, is crystalline, tasteless, sparingly soluble in acetic acid, alcohol, ether, and benzol; is readily soluble in chloroform; is colored orange-red by nitric and pale-violet by sulphuric acid, the latter color changing to dark-brown on heating.

13. MECONIDINE, $C_{21}H_{23}NO_4$, is amorphous, colorless or yellowish, tasteless, easily soluble in alcohol, ether, benzol, chloroform, and acetone. It yields very bitter unstable salts, and is dissolved by sulphuric acid with an olive-green, and by nitric acid with an orange-red, color.

14. LAUDANINE, $C_{20}H_{25}NO_4$, crystallizes in hexagonal prisms, melts at 166° (331° F.), is sparingly soluble in ether and cold alcohol, soluble in benzol, chloroform, and alkalis; in ferric chloride with an emerald-green, in nitric acid with an orange-red, and in sulphuric acid containing iron with a rose-red, color, the latter changing to violet on heating. The hydriodate is sparingly soluble in cold water; the hydrochlorate is nearly insoluble in solution of sodium chloride.

15. CODAMINE, $C_{20}H_{25}NO_4$, crystallizes from ether in large six-sided colorless prisms; is easily soluble in chloroform, benzol, ether, alcohol, and boiling water; forms amorphous bitter salts, and dissolves in nitric acid with a dark-green, and in sulphuric acid containing iron with a blue, color, changing to green and dark-violet on warming.

16. DEUTEROPINE, $C_{20}H_{21}NO_5$, homologous with cryptopine, requires further investigation.

17. LAUDANOSINE, $C_{21}H_{27}NO_4$, is soluble in alcohol, chloroform, ether, and warm benzol; the crystals fuse at 89° C. (192.2° F.). It neutralizes acids, and yields with hydriodic acid a sparingly soluble salt. Pure sulphuric acid colors rose-red, in presence of ferric salt brown-red, on warming green and deep violet.

18. PROTOPINE, $C_{20}H_{19}NO_5$, resembles cryptopine, and is with difficulty soluble in ether, alcohol, and benzol, more readily soluble in chloroform. The solutions of its salts do not gelatinize and have a bitter taste. The solutions in sulphuric acid turn yellow, red, and purple; in presence of ferric salt they are deep-violet.

19. HYDROCOTARNINE, $C_{10}H_{15}NO_5$, crystallizes in large colorless prisms, fuses at 55° C. (131° F.); volatilizes, partly unchanged, at 100° C. (212° F.); is easily soluble in benzol, ether, and alcohol, and forms readily soluble salts. It is formed from narcotine, besides meconin, by the action of nascent hydrogen.

From many of the above alkaloids derivatives have been obtained which are highly interesting in a scientific point of view, and which prove that at least between some of them there exists evidently a close relation. It is not unlikely that some of those enumerated above are the decomposition-products of others. This may most likely be affirmed to be true of Wittstein's *metamorphine* (1860), which was obtained in preparing morphine by Mohr's process (page 991), but has not been observed since. It liberated iodine from iodic acid, was colored red by nitric acid, but was not affected by ferric chloride. Hinterberger's *opiumine* was proved by Hesse to be impure narcotine.

The *proportion* in which the alkaloidal constituents of opium are present in the drug is, without doubt, largely influenced by the climate, the nature of the soil, and the treatment to which the milk-juice is exposed in obtaining the opium. Most of the pharmacopœias require dried opium to contain not less than 10 per cent. of morphine; good Smyrna opium frequently contains between 12 and 15 per cent. of it, but cakes taken from the same case are apt to vary considerably. Egyptian opium usually contains a smaller amount of morphine, varying from 6 to 12 per cent. Persian opium varies to a still greater extent, but much of that found in commerce is equal to the ordinary qualities of Turkey opium. East Indian opium, as a rule, is weak in morphine. It is sometimes as low as 2.5 per cent., more frequently perhaps between 3.5 and 5 per cent., but occasionally as high as 8 or 9 per cent. Most of the opium made in Europe has been of good and even of excellent quality. French opium yielded 14.4 to 22.8 (Guibourt), German opium 16.5 to 20, and from white poppy 6.8 per cent. (Biltz) of morphine. Opium made in Algiers from red poppy yielded 10.4 to 17.8 per cent., and from white poppy 1.5 to 8.5 per cent. of morphine. Several morphimetric assays of opium grown in the United States have been recorded; the lowest percentage of morphine, 4, was observed by Grahame; Procter obtained from other samples 7.4 and 9.15, Flint 9.34, and Wayne 10.2 per cent.

The other alkaloids have been observed in the following proportions:

Narcotine, 1.3 to 10.9 per cent.	Codeine, 0.2 to 0.4 per cent.
Pseudomorphine, 0.02 per cent.	Thebaine, 0.15 (to 1.0) per cent.
Narceine, 0.02 to 0.1 (0.7) per cent.	Papaverine, 1.0 per cent.
Rhœadine, minute.	Cryptopine, minute.
Lanthopine, 0.005 per cent.	Laudanine, 0.005 per cent.
Codamine, 0.003 per cent.	

MECONIC ACID (ACIDUM MECONICUM, *Br.*), $C_7H_4O_7$, discovered by Sertürner, is obtained by precipitating the concentrated infusion of opium with calcium chloride, and treating the calcium meconate repeatedly with warm diluted hydrochloric acid. It crystallizes in micaceous scales or rhombic prisms containing $3H_2O$, dissolves in 4 parts of boiling water, and is also soluble in alcohol. Opium yields 3 to 4 per cent. of it. It is a tribasic acid, and imparts to ferric salts a deep-red color, which does not disappear on the addition of dilute hydrochloric acid (difference from formic and acetic acids) or by the chlorides of gold or of mercury (difference from sulphocyanides). When boiled with water, or more rapidly when boiled with dilute hydrochloric acid, meconic acid is decomposed into carbonic acid gas and crystallizable *comenic acid*, $C_6H_4O_5$, which on being heated yields a

sublimate of *pyrocemic acid*, $C_6H_4O_6$. The two derivative acids likewise redden ferric salts, the last less deeply than the former.

T. and H. Smith (1862) exhibited *thelolactic acid* as one of the constituents of opium. This acid has the composition and physical properties of lactic acid, and, according to Buchanan (1870), is identical with the latter. It is present to the extent of about 1½ per cent., and is probably the decomposition-product of another constituent of poppy-juice. The same may also be said of the free acetic and traces of butyric acid announced by David Brown in 1876.

MECONIN is obtained from narcotine (see above), exists also in opium, and forms colorless shining prisms, which are inodorous, bitter, soluble in alcohol, ether, and slightly soluble in water. It was discovered by Dublanc (1832), and is also known as *opiacyl*. It melts in water at 77° C., and in the air at 110° C. (230° F.), and when evaporated with slightly diluted sulphuric acid gives a green color.

MECONOTOSIN, $C_8H_{10}O_6$, was obtained by T. and H. Smith (1878) from the mother-liquors left on the isolation of meconin, from which it separates in an impure state as brown leaf-like crystalline masses. When pure it is colorless, is freely soluble in alcohol, ether, and hot water, fuses at 88° C. (190.4° F.), and on evaporation with dilute sulphuric acid yields a red color, changing to purple.

Morphiometry.—In view of the variable quality of opium and of its liability to adulteration, the determination of the amount of morphine in it is frequently necessary, and must not be neglected if uniformity of strength of the pharmaceutical opium preparations is desired. The U. S. and British Pharmacopœias have adopted the method of Thiboumery and Mohr, and give the following directions:

"Opium, in any condition to be valued, 7 Gm.; lime, freshly slaked, 3 Gm.; chloride of ammonium 3 Gm.; alcohol, stronger ether, distilled water, each a sufficient quantity. Triturate together the opium, lime, and 20 Cem. of distilled water in a mortar until a uniform mixture results; then add 50 Cem. of distilled water, and stir occasionally during half an hour. Filter the mixture through a plaited filter 3 to 3½ inches (75 to 90 Mm.) in diameter into a wide-mouthed bottle or stoppered flask (having the capacity of about 120 Cem., and marked at exactly 50 Cem.), until the filtrate reaches this mark. To the filtered liquid (representing 5 Gm. of opium) add 5 Cem. of alcohol and 25 Cem. of stronger ether, and shake the mixture; then add the chloride of ammonium, shake well and frequently during half an hour, and set it aside for 12 hours. Counterbalance two small filters; place one within the other in a small funnel, and decant the ethereal layer as completely as practicable upon the filter. Add 10 Cem. of stronger ether to the contents of the bottle and rotate it; again decant the ethereal layer upon the filter, and afterward wash the latter with 5 Cem. of stronger ether, added slowly and in portions. Now let the filter dry in the air, and pour upon it the liquid in the bottle in portions, in such a way as to transfer the greater portion of the crystals to the filter. Wash the bottle, and transfer the remaining crystals to the filter, with several small portions of distilled water, using not much more than 10 Cem. in all, and distributing the portions evenly upon the filter. Allow the filter to drain, and dry it, first by pressing it between sheets of bibulous paper, and afterward at a temperature between 55° and 60° C. (131° to 140° F.). Weigh the crystals in the inner filter, counterbalancing by the outer filter. The weight of the crystals in Gm., multiplied by 20, equals the percentage of morphine in the opium taken."—U. S. The present *Br. P.* has adopted the same process.

"Take of opium 100 grains; slaked lime 100 grains; distilled water 4 ounces. Break down the opium, and steep it in an ounce of the water for 24 hours, stirring the mixture frequently. Transfer it to a displacement apparatus, and pour on the remainder of the water in successive portions, so as to exhaust the opium by percolation. To the infusion thus obtained, placed in a flask, add the lime, boil for 10 minutes, place the undissolved matter on a filter, and wash it with an ounce of boiling water. Acidulate the filtered fluid slightly with diluted hydrochloric acid, evaporate it to the bulk of half an ounce, and let it cool. Neutralize cautiously with solution of ammonia, carefully avoiding an excess; remove by filtration the brown matter which separates, wash it with an ounce of hot water, mix the washings with the filtrate, concentrate the whole to the bulk of half an ounce, and add now solution of ammonia in slight excess. After 24 hours collect the precipitated morphine on a weighed filter, wash it with cold water, and dry it at 212° F. It ought to weigh at least from 6 to 8 grains."—*Br.*, 1867.

Mayer (1863) recommended a similar method, but substituted baryta for lime, and, instead of weighing the morphine, estimated it by his test solution.

Prollius (1877) devised a process which is also recommended by Flückiger (*Pharma-*

cographia, 2d ed., p. 63): A tincture is made from 10 Gm. of opium and sufficient alcohol spec. grav. .950 to obtain 100 Gm. of filtrate; add to this 50 Gm. of ether and 2 Gm. of ammonia-water spec. grav. .960; collect the crystals of morphine after a day or two, and dry them at 100° C. (212° F.).

The following is a modification of this process: "Agitate 8 Gm. of powdered opium with 80 Gm. of water, and after half a day filter. Mix 42.5 Gm. (equal to one-half of the total) liquid with 12 Gm. alcohol, 10 Gm. ether, and 1 Gm. ammonia-water, and set aside for 12 hours in a closed vessel at a temperature of 10° to 15° C. (50°–59° F.); then transfer to a well-dried and tared filter of 80 Mm. (about 3¼ inches) diameter, wash the morphine crystals twice with a mixture composed of 2 Gm. each of alcohol sp. gr. .894, water, and ether, and dry them upon the filter at 100° C. (212° F.); their weight should not be less than 0.4 Gm. (= 10 per cent.)."—*P. G.*

Numerous other processes and modifications have been recommended. The principal difficulties encountered in most of them are (1) the large quantity of water required for extracting the morphine, frequently rendering the concentration of the solution necessary, which should always be accomplished at a moderate heat; and (2) the impurities which are always precipitated with the morphine, and which consist of coloring matter with or without narcotine; the latter may be removed by ether, but in decolorizing the precipitate, either by alcohol or with the aid of animal charcoal, there ensues inevitable loss.

Pharmaceutical Preparations.—*OPIMUM DENARCOTISATUM*, Denarcotized opium. Powdered opium, containing 14 per cent. of morphine, 100 parts (1 oz. av.); stronger ether 1000 parts (10 oz. av. or 13½ fluidounces); sugar of milk, in fine powder, a sufficient quantity; to make 100 parts. Macerate the powdered opium with 500 parts of stronger ether in a well-closed flask for 24 hours, agitating from time to time. Pour off the clear ethereal solution, and repeat the maceration with 2 other portions of the ether, each of 250 parts, first for 12 hours, and the last time for 2 hours. Collect the residue in a weighed dish, dry it, first by a very gentle heat, and finally at a temperature not above 85° C. (185° F.), and mix it thoroughly, by trituration, with enough sugar of milk to make the product weigh 100 parts (1 oz. av.). Instead of taking 100 parts of powdered opium, containing 14 per cent. of morphine, a proportionately smaller quantity of powdered opium of any higher percentage of morphine may be taken. The proper quantity, in parts by weight, for the above formula is ascertained by dividing 1400 by the percentage of morphine in the powdered opium selected.—*U. S.*

LIQUOR MORPHINÆ BIMECONATIS, *Br.*, Solution of bimeconate of morphine.—Dissolve morphine hydrochlorate 9 grains in 2 or 3 drachms of warm distilled water; add solution of ammonia sufficient to precipitate the morphine; cool, filter, wash the precipitate well with distilled water; drain; mix with sufficient water to produce 1½ oz.; then add rectified spirit ½ fluidounce and meconic acid 6 grains; dissolve.—*Br.*

This is a colorless or nearly colorless liquid, in which potassa produces a white precipitate soluble in excess, nitric acid an orange-red color, and ferric chloride a blood-red color, which is not changed by diluted hydrochloric acid. The solution contains about 1½ per cent. of morphine bimeconate ($C_{17}H_{19}NO_3 \cdot C_7H_5O_7$), and is of about the same morphine strength as tincture of opium. Procter (1867) precipitated, from an infusion of 5 troyounces of dry opium, the meconic acid by lead acetate and the morphine by ammonia, decomposed the lead precipitate by H_2S , dissolved in this liquid the morphine, diluted with water to 3 pints, and added alcohol 1 pint. This process yields a reddish brown solution.

AQUA OPII, Opium-water. From a mixture of 1 part of bruised opium and 10 parts of water distil 5 parts. It is colorless and has a slight narcotic odor.

Off. Prep.—Containing opium, extract or tincture of opium: *Acetum opii*, *U. S.*; *Emplast. opii*, *U. S.*, *Br.*; *Enema opii*, *Br.*; *Extract. opii*, *U. Physiological Action.—*On Animals*: In the lower animals opium affects the spinal marrow more than the brain, and the latter organ in proportion to the rank of the animal among organized beings. Experiments upon frogs prove that opium throws these animals into tetanic spasms, however it may be introduced and whether the brain is detached or not. The same effects are produced in lizards. Birds will bear enormous doses of opium in comparison with those which may be given to man; but its effects are

by no means uniform, for in individual cases the narcotic exceeds the tetanizing or paralyzing influence of the drug. Not infrequently a pigeon, for example, will survive the ingestion of 20 grains of opium—a dose far exceeding that which would be fatal to the strongest man—yet the same bird will, under the influence of the hypodermic injection of a relatively small dose of morphine, succumb, and usually with a predominance of spinal phenomena. A similar illustration is presented by herbivorous quadrupeds: for while even 30 grains of opium produce no effect when introduced into a rabbit's stomach, sleep and contracted pupils are produced by throwing laudanum into the pleural cavity or a solution of morphine into the connective tissue. Unless we suppose that the active constituents of opium are decomposed in the stomach of these animals, such opposite results appear to be quite inexplicable.

On Man: In doses varying from a $\frac{1}{4}$ grain to 1 grain, opium produces usually a soothing and luxurious calm of mind and body, followed, in the course of 40 or 50 minutes, by a disposition to sleep; or, if sleep does not take place, the body and mind enjoy a sense of repose from external impressions, while the mind is filled with dreamy and generally pleasant ideas. The pulse at first is quickened, but gradually becomes slower, the mouth grows dry, and the skin moist. Excited consciousness is followed by sleep, which is natural in its phenomena, and from which one awakes refreshed. Larger doses, as from 1 to 3 grains, occasion turgor and redness of the face, heat and fulness of the head, flashes of light before the eyes, and contraction of the pupils. The mind is excited, even to delirium; the pulse is full, tense, and frequent; the skin is hot and dry, and often there is vomiting. Depression follows, with a slow and sometimes irregular pulse; dulness oppresses all the functions of relation, and the mind is torpid; the muscles lose their co-ordinating action, and the gait is sluggish and staggering. Deep sleep, or rather coma, succeeds; the breathing is stertorous, the skin pale and damp, and the hands and feet cold. The return to consciousness is attended with depression of mind and body, headache, thirst, nausea, and constipation. In narcotism by opium, when an excessive dose has been taken, no stage of excitement occurs; giddiness is speedily followed by insensibility and immobility, the respiration is slow and stertorous, and then scarcely perceptible; deglutition is suspended; the pupils are extremely contracted; the face is pale and cadaverous; the muscles of the limbs are relaxed. Vomiting sometimes occurs, but more usually in fatal cases coma continues until death, which is sometimes preceded by convulsions. After death from opium-poisoning the convolutions of the brain are flattened, the vessels of the cerebro-spinal axis are gorged with black blood, and the capillaries of the brain on section give out minute drops of the same fluid. A serous liquid is usually found in the ventricles and beneath the cerebral surface of the arachnoid. The lungs, heart, liver, and spleen are in most cases distended with dark and fluid blood. It is worthy of notice that some persons who have recovered from the immediate effects of a poisonous dose of opium have afterward died of congestion or consolidation of the lung, doubtless induced by the narcotic effects of the poison (Shapleigh).

To render more intelligible the operation of opium, it is necessary to point out the details of its action upon several of the organs. Contraction of the pupil is attributed, on the one hand, to its sedative action upon the sympathetic nervous system, in consequence of which the capillary blood-vessels of the iris become dilated and distended, and the pupil consequently contracted; on the other hand, it is ascribed to a stimulation of the oculo-motor centres. The former opinion seems the more probable of the two. Opium affects the digestive function by blunting the gastric sensation to which we give the name of hunger, and diminishing the demand for food by checking all the tissue-changes which create that demand. At the same time it increases thirst, probably by rendering the gastric mucous membrane dry, as well as by accumulating solid effete matters in the blood. In the same manner it impedes digestion and retards absorption. The vomiting which it sometimes occasions, even when administered by the rectum or when morphine is given hypodermically, appears to be of cerebral origin. Opium tends to constipate the bowels by benumbing their muscles, as well as by diminishing their proper secretions and those of the liver and pancreas. When the drug is habitually used these effects become less marked. As already mentioned, the primary effect of a medicinal dose of opium is to render the pulse fuller and more frequent, but as the soporific operation is developed the pulse becomes slower without losing its fullness. The ultimate narcotic effects upon the pulse are to render it small, weak, and irregular. That these phenomena arise through the action of opium upon that portion of the nervous system which regulates the movements of the heart and arteries must be taken for

granted; but the attempts made to explain it by defining the special nervous centres upon which it depends, and its mode of action, are more ingenious than satisfactory. The same remark is measurably applicable to the action of opium upon the respiration. Respiratory movements are rendered progressively slower, until in complete narcotism they become scarcely perceptible. Hence the blood is but partially oxygenated, and, being unfit for returning to the heart, it stagnates in the lungs. Hence, too, the blood of those who perish in opium-narcosis is intensely black, and death occurs by gradual asphyxia. Hence, moreover, the most direct remedy for this condition is the introduction of oxygen into the lungs. Upon the kidneys, as upon all other glands, the action of opium is to check secretion, and at the same time to prevent the discharge of what is secreted by paralyzing the bladder. Its power of lessening renal secretion is strikingly exhibited in diabetes and hydruria. While diminishing glandular and mucous secretions, opium greatly augments the perspiration, so that a conspicuous symptom among its toxic effects is profuse sweating, and it may be used as one of the surest and most perfect of all diaphoretic medicines. It is very apt to excite itching of the skin, and often produces an erythematous eruption.

The attempts to explain the operation of opium have not been much more satisfactory than in the case of other really efficient medicines. Its local anæsthetic action, and that which its internal use manifests when less than soporific doses are administered, are absolutely unintelligible. Its hypnotic action, it can scarcely be doubted, depends in part upon the same anæsthetic virtue exercised upon the brain-tissue. In part, also, it seems to be explicable by the power, several times above referred to, which opium exerts in contracting the capillary blood-vessels, and thereby diminishing the supply of the natural stimulant of the organ, arterial blood. This view is rendered more probable by the consideration that belladonna, which prevents sleep, dilates the capillary blood-vessels as much as opium contracts them. It is further supported by the fact that poisonous doses of opium, producing not sleep but narcotism, dilate the capillaries by paralyzing them. Yet, after all, nothing known of the action of opium can dispense with that innate quality of the drug, our ignorance of whose nature used to be concealed under the delusive phrase "vis dormitiva."

It must be constantly borne in mind that the action of opium, like that of all agents which especially influence the nervous system, is greatly modified by numerous causes besides its mere dose. Thus it acts with extreme energy in the very young, because their nervous systems are highly susceptible; and ordinary doses are unsafe in the old, because, their eliminating functions being feeble, the medicine remains in their blood. For the former reason, probably, females are, as a rule, more readily affected than males by opium. All nervous, susceptible persons feel its influence speedily, and often in an abnormal manner, being unduly excited by ordinary doses. On the other hand, as in the case of alcohol, there are persons who can take with impunity doses of opium which to others would be distressing or even fatal. There are those, also, in whom the habit of using opiates has created a relative insensibility to the action of medicinal doses. In other cases extreme pain, like that of tetanus or biliary and nephritic colic, may neutralize the narcotic operation of the largest medicinal doses.

In a work like the present a detailed account of the morbid effects produced by the habitual use of opium would be out of place. They have been briefly summarized under MORPHINA, and need not be repeated here. An elaborate discussion of the subject is contained in a work of one of the present authors (*Therapeutics and Materia Medica*), where the opium habit is illustrated by many examples, and its influence on health and life considered. To the cases there cited, and which prove that the slavery of this habit may be as prolonged as it is terrible, may here be added one of more recent publication. It is that of a former officer in the English army, who at the alleged age of one hundred and eleven was still living in New York. "He had been an opium habituate for seventy years," and at one time his daily consumption of the drug was 90 grains (Mattison, *New York Med. Record*, xii. 239). His extreme longevity makes any detail of its morbid effects superfluous. Indeed, the chief disorders it produced consisted of obstinate constipation when the dose of opium was very large, and diarrhœa when it was suspended or greatly diminished. (Respecting the opium habit, the following are a few of the articles that may be consulted: Mattison, *Phila. Jour. of Phar.*, Apr. 1879, p. 209, and *N. Y. Med. Record*, xxiii. 621; Kane, *Med. Record*, Nov. 1881, p. 511; Francis, *Lond. Med. Times and Gaz.*, Jan. 1882, pp. 87, 116; Myers, *Ibid.*, June, 1882, p. 672; Moore, *Edinb. Med. Jour.*, xxviii. 958.)

The several constituents of opium which have been isolated by chemical analysis man-

ifest various modes of action, which differ more or less widely from that of opium itself. While *morphine*, as we have shown elsewhere, very nearly represents the crude drug, and codeine, meconine, papaverine, cryptopine, and narceine share with it a certain soporific virtue, the remaining elements, narcotine, thebaine, etc., are almost if not entirely destitute of this quality. The following statements represent the ambiguous condition of existing knowledge on these subjects:

Narcotine was first introduced as an anti-periodic, and, although freely given, was not suspected of possessing narcotic properties. Experiments upon animals prove it to be eminently a tetanizing agent, and productive at the same time of great depression; yet some observers report its possession of a slight narcotic power. According to others, this power is distinctly manifested in man by doses of from 10 to 20 or 30 grains (Gm. 0.60–2), yet it is certain that it has been administered as a tonic and anti-periodic in 30-grain (Gm. 2) doses without producing any narcotic effects. The conclusion almost necessarily is, that the alkaloid was not pure in the former case, but contaminated with morphine. *Papaverine* is, on the one hand, alleged to be hypnotic, even the "prime hypnotic element of opium," an arterial and nervous sedative; and, on the other, it is by turns pronounced inert, tetanizing, relaxing, and a heightener of reflex action. Physiological experimenters have demonstrated that *thebaine* is eminently a convulsifying agent, the "most potent of all the poisonous constituents of opium." In man it is anodyne and soporific in the hypodermic dose of $1\frac{1}{2}$ grains (Gm. 0.10), and is nearly equivalent to $\frac{1}{4}$ grain of a salt of morphia, while it does not occasion headache and nausea. *Cryptopine* appears to be closely analogous in its action to thebaine, tetanizing some of the lower animals, convulsing others. In man it acts like morphine, but without the unpleasant consequences due to the latter alkaloid. It is stated to be about one-fourth as strong as morphine. *Meconine*, when administered even in large doses hypodermically to large animals, and by the mouth to man, appears to be quite inert; but hypodermically, in doses of from $\frac{1}{2}$ grain to $1\frac{1}{2}$ grains (Gm. 0.03–0.10), it produces in man a moderately hypnotic effect. The action of *codeine*, which is now official, is discussed elsewhere. *Narceine* was once proclaimed to possess all of the virtues, without any of the defects, of morphine, and as being operative in an equal dose. The usual contraindications of physiological experiment and therapeutical observation have only left the fact to survive that it is soporific for cold-blooded animals, and for man a feeble though pure hypnotic in the dose of 5 grains and upward, but, being at the same time rare and costly, it is practically useless as a medicine. The peculiar action of *apomorphine* has been fully described elsewhere (p. 222); it may suffice in this place to say that it is an emetic and general depressant. According to Ott, *chlorocodide* is a tetanizing agent; *apocodine* produces vomiting, coma, and death; *cotarnine* is soporific, and paralyzes the motor nerves; *hydrocotarnine* is narcotic and convulsant; *laudanosine* and *laudanine* are tetanic agents. In 1878, Bardet undertook a course of experiments to determine, if possible, the relative value of the principal constituents of opium, and reached the following conclusions: Codeine in small doses is null, in large doses a fruitless and distressing agent; narceine has either no real existence or is totally inert as a narcotic; and morphine "is the sole useful and narcotic alkaloid of opium" (*Bull. de therap.*, c. 78).

In 1883, Von Schroeder pursued this investigation much more thoroughly and minutely (*Archiv. f. exp. Pathol.*, etc., xvii. 96). Space is wanting to describe in detail even his results, but they proved that morphine is the only true narcotic element of opium, and that codeine, papaverine, narcotine, and thebaine are mainly tetanizing agents and but slightly narcotic. Narceine he held to be wholly inoperative. Thus the most recent results as substantially agree as the early ones were at variance with one another.

Medical Uses.—The different modes of action of opium, according to its dose, upon the two great vivifying elements of the animal economy, its stimulant and sedative operations upon the nervous and circulatory systems, and its directly anæsthetic influence in all doses, render it the most useful of all medicines, as well as the most multifarious in its applications. It relieves pain, allays agitation, delirium, and spasm, restrains tissue-change, secretion, and hæmorrhage, and both directly and indirectly supports the powers of the system. By the possession of these manifold virtues it becomes the most fitting associate of numerous other medicines, the operation of which it moderates, exalts, or directs.

Fever. It is an old precept, which all judicious experience has confirmed, that opium ought not to be prescribed at the onset nor at the climax of a continued fever, but during the augment to appease its violence, and during the decline to support the strength and calm the nervous symptoms which denote exhaustion. In *typhus* its greatest usefulness

is not when the strongest tendency to stupor exists, but when muttering delirium, jactitation, tremor, and spasm denote exhausted nervous power; but even then it must be used in such doses only as revive, and not in such as tend to oppress, the brain. In the rarer cases of this disease presenting violent delirium, a furious aspect, suffusion of the eyes, constant raving and muttering, and perfect sleeplessness, moderate doses of a liquid preparation of opium, associated with tartar emetic, according to a former practice, or with veratrum viride or digitalis, as more recently employed, will often render the patient tranquil and induce refreshing sleep. These remarks are equally applicable to all forms of disease when the *typhoid state*, characterized by the above phenomena, is present, and especially to *typhoid fever*, and to *small-pox* as it occurs in adults. But opiates in the diseases of children, and especially in their eruptive fevers, are seldom useful, and often involve serious risk. Another object of employing opium in the exanthematous fevers is to hasten the development of the eruption when it is tardy and imperfect. Under such circumstances the medicine should be given in small and repeated doses, and associated with external heat and rubefacients and internal diffusible stimulants. Before the introduction of cinchona, opium was generally used to abort the paroxysms of *periodical fevers*, which it did by creating a vascular excitement opposed to the formation of the chill, and inducing artificially a diaphoresis which also prevented that stage of the attack. In the same manner it is often now associated with quinine, whose specific operation it favors. Another mode of using opium in intermittent fever is to administer it in so large a dose as to hold the nervous system in a state of immobility, and so prevent the formation of the paroxysm.

Inflammation is less directly under the control of opium than idiopathic fever, yet its judicious employment, by lessening pain, tends to prevent an aggravation of the disorder and to allow the natural recuperative powers their full operation. In chronic inflammations, also, attended with constitutional irritation and hectic fever, opium exerts a salutary restraining influence. After severe operations it tends to prevent the irritative fever which the shock of pain and loss of blood, and the consequent reaction, are apt to excite. As a rule, the dose required is large and sedative. In *hæmorrhage*, even of the active sort, opium is sometimes of service by diminishing the agitation upon which its continuance depends, and especially by allaying the excitability of the nervous system of the heart; but its greater utility is in cases of passive hæmorrhage accompanied by a similar excitability. Possibly, also, it may directly contract the capillaries. In *senile gangrene* it is generally employed, probably on account of its analgesic and stimulant operation.

All forms of *pain* are palliated by opiates, but the more independent pain is of material lesions, as in pure *neuralgia*, the more efficient are these remedies, unless, perhaps, when the narcotic operation suspends the action of the physical cause of pain. All forms of *spasmodic pain*, of the bowels, bladder, uterus, gall, and urinary ducts, etc., are lessened by suspending the spasm in which the pain arises. Pain due to movements of the affected part is directly palliated by opium, and indirectly by promoting rest. In nearly all painful disorders the dose of opium must be proportioned to the degree of pain. The tolerance of large doses of the drug during severe pain, and also in prolonged spasmodic attacks like tetanus, is a remarkable fact. Opium is seldom appropriate for pain within the head; it may dangerously mask this symptom in other cases where pain is the chief indication of the disease. Of the latter, strangulated *hernia* is an example.

Sleeplessness is relieved by the direct action of opium, and also indirectly, in so far as opium removes the cause that prevents sleep, whether it be pain, mental excitement, or exhaustion, etc.; but very often it fails of its effect, although given in large doses, in such excessive excitement as occurs in *mania a potu*, acute *insanity*, *meningeal inflammation* in some of its forms, etc. Moreover, if long continued, its utility as a hypnotic is more than counterbalanced by the derangement of digestion, secretion, etc. which it induces, particularly as its original effects can only be maintained by largely increased doses of the drug. In *puerperal insanity* it is more beneficial than in other forms of mental disorder, particularly when morphine is used hypodermically. The treatment of *delirium tremens* by large doses of opium, which at one time prevailed, was most unfavorable in its results; and if the drug is used at all in this disorder, its doses should be small and repeated, so as to produce a primary stimulant and not a narcotic operation. We have observed with intense regret a tendency to revive the practice of administering large doses of opiates in this disease. In one case 5 grains of morphine were given subcutaneously in 2 doses, and in another no less than 8 grains within 4 hours (*Med. Times and Gaz.*, March 11 and 18, 1876). The mortality of delirium tremens under the opium

treatment, as formerly practised, was enormous, and is remembered by the present writer as one of the most painful features of his hospital life. Since that time, with an expectant and rational treatment, he has rarely had occasion to witness a death from this disease. In *epidemic cerebro-spinal meningitis* opium is probably the most efficient of all the remedies that have been employed. But its utility is most conspicuous in those cases of the disease in which spasm (*i. e.* spinal irritation) predominates over septic phenomena, and when it is administered steadily from the commencement of the attack. *Sanstrolce* marked by nervous symptoms, such as convulsions, twitchings, delirium, and general excitement, is greatly benefited by the hypodermic injection of morphine. This medicine may be used as a palliative in *epilepsy*, *hysteria*, *clampsia*, and *spasm of the glottis*; and although it is contraindicated in obstruction of the kidneys, as in Bright's disease, it is nevertheless of great value in *uræmic convulsions*, especially in the form of hypodermic injections.

In obstinate cases of *chorea* the sustained use of opium has sometimes been followed by a great reduction of the spasmodic movements, and even by cure. Hardly any remedy has effected as much good in *traumatic tetanus* as opium, even when given by the mouth, although a large portion of the drug is wasted by this mode of administration. The liquid preparations are preferable, and superior to these again is the hypodermic injection of morphine. Neither method should exclude the due employment at the same time of other remedies, and especially of counter-irritation of the spine and the use of alcohol. In this disease larger doses of opiates are required than in any other. In the somewhat analogous affection produced by *strychnine-poisoning* subcutaneous injections of morphine have proved curative. The use of opiates in *neuralgia* is most efficient when the salts of morphine are injected hypodermically, as is elsewhere at greater length described. (See MORPHINE.) This statement applies to internal as well as external neuralgia.

In diseases of the respiratory organs *pain* and *cough* are the symptoms which especially call for the use of opiate preparations, which relieve the former directly as well as diminish the violent movements accompanying the latter symptom. So far as the pain caused by coughing depends upon pleural inflammation or upon the action of muscles affected with rheumatism, opium affords certain relief, while it palliates also the painful sensations accompanying acute bronchitis. But as coughing is largely a conservative act, tending to prevent the accumulation of secretions in the bronchia, opium must not be employed in such doses as tend to prevent this salutary operation; hence it must be cautiously used, if at all, when the bronchia are filled with their secretions. In the forming stage of *pulmonary catarrh* or *bronchitis*, when the air-tubes are dry and irritable and coughing painful, opium, especially with ipecacuanha, as in Dover's powder, will sometimes mitigate, or even terminate, the attack by promoting the pulmonary and cutaneous secretions. Opium has been used in the form of morphine, hypodermically, with reported advantage in arresting the development of *autumnal catarrh*. In *pneumonia* and *pleurisy* its use should be restricted to moderating cough and pain; and the same may be said of chronic *phthisis*. In the latter, if habitually used, it is very apt to impair digestion and hasten the patient's decline, but is nevertheless almost indispensable when the cough is harassing. It may sometimes be given in an atomized solution more efficiently than when otherwise administered. In *asthma* hypodermic injections of morphine are efficient palliatives. In the various affections of the heart, of which *angina pectoris* is a more or less frequent symptom, opium, but still more morphine, is an invaluable palliative, and that without too closely regarding the special lesion upon which the pain and the disordered action of the heart depend. Of heart lesions which accompany such attacks those of the mitral valve are the most frequent. For the relief by opium of all symptoms depending upon a positive or relative debility of the heart the medicine must be given so as to stimulate; that is to say, in small and repeated doses.

Among diseases of the digestive organs the symptoms most appropriately treated by opium are *vomiting*, *pain*, and *diarrhoea*. All forms of vomiting are more or less under its control, as that of *sea-sickness*, of *pregnancy*, of *reflex irritation* generally, and of diseases affecting the stomach itself. In the last opium is often given in the form of an old or hard pill, but the hypodermic injection of morphine is usually more efficient. *Simple ulcer* of the stomach as a cause of vomiting is sometimes treated with opium and its preparations, but they are unnecessary when the diet is properly regulated and bismuth or lime-water is employed. In pure *gastralgia* these medicines are often extremely valuable as palliatives, but other means are required to cure the disease through the removal of its cause. When used, they should be administered 10 or 15 minutes before meals, and also when a paroxysm is imminent.

Of the use of opiates in *diarrhœa*, it may be remarked that the less this symptom depends upon material lesions or upon irritating crude ingesta, the more efficient are opium and its preparations as remedies. Indeed, they only hasten somewhat the natural cure by moderating the peristaltic action and diminishing the secretions of the intestine. Otherwise, they act only as aids to absorbents and astringents, such as chalk, tannin, etc. In *dysentery* opium is of less value for its curative properties than as a palliative of the tormina and tenesmus which belong to the active forms of this disease; but even these symptoms are more successfully relieved by the evacuant method, either alone or in alternation with the administration of opium by the mouth and by the rectum in enemata or suppositories. When once the violence of the disease is subdued, moderate doses of opium greatly hasten its termination. In the chronic form of dysentery the main reliance must be upon diet, especially upon a milk diet, but opium with astringents is the best medicinal remedy. In *lientery* opium, with or without astringents, is almost indispensable. It is by far the best remedy in *cholera morbus*. No evacuant medicines need be first administered. A grain of opium should be given every half hour in severe cases, the patient refraining from the use of liquids as much as possible. Enemata of laudanum should also be employed, or the treatment may be confided to the hypodermic use of morphine. Care should be taken not to exceed the needful quantity of the drug administered, on account of the depression which is apt to follow the use of large doses. In *epidemic cholera*, depending as it does upon a specific poison, opium cannot be as confidently relied upon; indeed, the records of its use in this disease are extremely discouraging. But in the forming stage, or that of premonitory diarrhœa when that stage exists, opium with chalk and vegetable astringents is invaluable. The tender age and great susceptibility to the influence of opium of the ordinary subjects of *cholera infantum* render opium an unsafe remedy for that affection, notwithstanding the apparently clear indications for its use in the nature of the disease. If used at all, it should be in the form of Dover's powder alone or along with gray powder or calomel.

The symptom *colic*, as a form of pain, is of course amenable to a treatment by opiates, but it is a symptom connected with very numerous and dissimilar conditions. In the ordinary form, due to flatulent dyspepsia of the bowel, opium with diffusible or carminative stimulants affords prompt relief. In *painter's colic*, which is attended with intestinal contraction and spasm, opium is the best remedy, especially in alternation with purgatives. *Biliary* and *nephritic colic* are most efficiently treated by opium; and when pain arises from any of the various acute forms of intestinal displacement (*invagination, hernia*), the moderate but sustained use of opiates is infinitely preferable to the too common method of attempting to force an evacuation by means of purgatives. In all of these cases the hypodermic use of morphine is preferable to opium internally. (Compare Post, *New York Med. Record*, xxi. 431.) Of the several forms of *peritonitis*, those only which are due to traumatic causes, such as external violence and perforation or irritation of the peritoneum by diseases of the organs which it covers, are favorably influenced by opium; but in these it is indispensable, for by its means alone can that repose of the abdominal organs be secured which is necessary to control the degree and extent of the inflammation. In *puerperal peritonitis*, although it has been employed in heroic doses and emphatically praised, it has not been generally recognized as appropriate.

Among diseases of the genito-urinary organs opium is an efficient palliative in *nephritic colic*, already referred to, and in all the spasmodic affections of the *ureters*, *bladder*, and *urethra*, such as arise during calculous disorders and inflammation of these several parts. Thus it is a usual remedy for *chordee*, although generally associated with camphor. In all of these cases it is best administered by the rectum. It should never be used in *Bright's disease*. Opium is superior to any other single medicine in diminishing the quantity and the saccharine quality of the urine in *diabetes* when administered in full and progressively increasing doses until a partial tolerance of the drug is induced. At the same time it lessens the thirst and hunger, renders the skin softer, and the mind less despondent. Its most efficient coadjutors are exercise and appropriate food. (See case, *Boston Med. and Surg. Jour.*, Sept. 1881, p. 277.) It is an efficient palliative of the *grinding pains* which precede actual labor, and for those uterine contractions which so often lead to *abortion* or premature labor. Hypodermic morphine injections are more efficient than opium in such cases. The same means are frequently employed in *dysmenorrhœa*. In these various affections, and in all others within the pelvis for which opium is appropriate, suppositories containing this drug or its derivatives, and enemata with laudanum, are especially indicated. In constitutional *syphilis* opium has been erroneously represented as a means of cure. It only allays constitutional irritability and procures

rest from nocturnal pains. In the primary forms of the disease it is useful as a dressing for irritable sores.

Muscular rheumatism may generally be relieved by opium, used so as to produce free diaphoresis, and especially in the form of Dover's powder. It is much more efficient in the forming stage of the attack than later. In *articular rheumatism* it has sometimes been used as an exclusive treatment, but with very unfavorable results, in that it augments the frequency and the gravity of the cardiac complications. It is, however, valuable as an anodyne and soporific, thereby husbanding the patient's strength while the disease is removed by eliminative medicines. In the same manner it is useful in *gout*, and particularly its liquid preparations. When this disease becomes *retrocedent*, and especially when it attacks the stomach, opiates associated with diffusible stimulants are the most reliable remedies. Wine of opium or laudanum should then be administered in doses of from 40 to 60 drops (Gm. 2-3) every hour by the mouth or rectum, or morphine may be employed hypodermically.

The use of opium in poisoning by BELLADONNA, ATROPINA, STRYCHNINA, and PHYS-OSTIGMA will be found described under those several titles.

As a *local remedy* opium has already been noticed in connection with various painful affections; the uses of morphine in this respect are even more numerous. But the liquid preparations of opium in liniments, epithems, poultices, etc. as topical anodynes are more habitually employed. A watery solution is used as a dressing for irritable *ulcers*; the wine of opium is an admirable anodyne and stimulant in granular *conjunctivitis* and *ulcers of the cornea*; in *earache* laudanum and sweet oil are applied on cotton to the auditory canal; in *toothache* a small piece of opium may be introduced into the hollow of a carious tooth, or, still better, a solution of morphine in chloroform, saturating a plug of cotton, may be similarly applied, or in rheumatic toothache the gums may be bathed with laudanum. In *paronychia* and numerous other forms of painful local inflammation the anodyne operation of opium and its preparations lessens the inflammation by assuaging the pain.

The rational and habitual method of treating *poisoning by opium* consists in emptying the stomach of whatever portion it still contains of the poison, and in keeping the nervous system stimulated and the respiratory apparatus active, and so preventing or diminishing narcotism until the poison is eliminated from the system. For the first purpose emetics are indicated; *e. g.* large draughts of warm salt and water, mustard-water, or water containing ipecacuanha, sulphate of zinc, or sulphate of copper. Tartar emetic should never be prescribed, unless other evacuants fail. It has been successfully employed by the rectum and also by the veins. Vomiting should be favored by tickling the fauces. If these means are not promptly and completely efficient, the stomach-pump should be resorted to. When solid opium has been taken—which, however, is rarely the case—the stomach-pump is of secondary importance. To counteract narcotism, stimulants of the general nervous system and of the respiratory apparatus are employed, both internally and externally. One of the best, as well as the most accessible, is a strong infusion of coffee, given without sugar or cream, but with a small proportion of brandy or whiskey. A strong infusion of green tea is nearly as efficient. The mydriatics (belladonna and stramonium) have been employed as direct antidotes. Their value is estimated in the articles devoted to those medicines. A single illustration of the efficacy of the former may be mentioned here: A man had taken 2½ ounces of laudanum, none of which was rejected or removed, and no remedies were applied until 2 hours had elapsed. Then ¼ grain of atropine was given hypodermically in 4 hours and in six doses. The man recovered (Bryant, *Med. Record*, xviii. 648). Of external means for stimulating the nervous system, one of the best is to cause the patient to walk, as long as he is able, supported between two assistants, while his attention is kept aroused by conversation or by flagellating the back with a whip of fine cords or a bundle of birch-twigs. Unless the impression made is sharp it is almost useless. Hence the electrical brush answers remarkably well for this purpose. Cold, or alternate hot and cold, affusions, made to the upper part of the body, produce a powerful impression and excite the respiratory act. The partial restoration of consciousness by these means is sometimes accompanied by a renewal of the susceptibility of the stomach, and the emetics it may contain excite vomiting. Ammonia may be held to the nostrils occasionally, and mustard applied over the epigastrium and heart; but the irritation produced by these agents makes it necessary to watch their action. Artificial respiration, although inferior to the other means described, has occasionally been used with success. In infants the natural resiliency of the ribs renders this agency especially useful.

The cure of *opium-eating* consists either in gradually diminishing the quantity of the drug consumed, and the substitution for it of aromatic and stimulant tonics, such as ginger, black pepper, columbo, quassia, etc., or in the abrupt cessation of the practice. Both methods count a few successful cases, but the latter, while the more efficient, is the more arduous. In certain inveterate cases it is claimed that a cure has been effected by prescribing 40 minims of dilute phosphoric acid and 80 minims of tincture of lupulin an hour before meals in a wine-glassful of water. At night sleep may be promoted by tincture of cannabis and Hoffmann's anodyne. The exhausted digestive function should be allowed to revive under simple food, such as milk and rich broths, in small quantities at a time. Exercise and bathing should be insisted upon, and zinc, quinine, and iron may be cautiously administered.

Administration.—The average *dose* of opium for an adult is 1 grain (Gm. 0.06). This is usually an objectionable form of its administration when the medicine must be repeated. In that case a liquid preparation should always be preferred. When a gradual operation is intended an old opium pill is the best, since its slow solution prolongs its action and extends its local influence over a larger surface. It is also much less apt than freshly-made opium pills to occasion nausea. The after-effects of opium are supposed to be mitigated by bromide of potassium in a full dose administered along with the opiate. This apparent operation is rather due to the fact that with a full dose of the bromide a smaller one of opium is necessary. Owing to the extreme susceptibility of children to opium, it should rarely be prescribed for them in the solid form. Suppositories of opium for the rectum and vagina are very useful in local disorders of the pelvic organs, and the rectal forms may also be used when for any reason the drug cannot be administered by the mouth. But they are less prompt in action than enemata of liquid opiates.

Denarcotized opium is supposed to be free from narcotine, and, according to some, from thebaine also, and therefore that it is less apt than opium to excite those distressing nervous symptoms which the whole drug sometimes occasions. Its *dose* is the same as that of opium.

Opium-smoking has been recommended by Thudicum as one of the most effectual remedies for commencing *coryza*, *hay fever*, *bronchitis*, obstinate *coughs*, various *neuralgia*, and *hyperæsthesiæ* generally. The watery extract is alone suitable for the purpose. (For the mode of using opium in this manner see Kerr, *Med. News*, xliii. 402.)

OPOPANAX.—OPOPANAX.

A gum-resin obtained from *Opopanax Chironium*, *Koch*, s. *Pastinaca Opopanax*, *Linneé*. *Nat. Ord.*—Umbelliferæ, Orthospermæ.

Origin.—The opopanax-plant is a perennial herb, with a long, thick, and fleshy root, a tall stem, large pinnately decomposed leaves, yellow flowers, and dorsally flattened fruit containing many oil-tubes. It is indigenous to Southern Europe. On wounding the root or lower part of the stem a yellowish milk-juice exudes, which after hardening constitutes opopanax.

Description.—The best quality of opopanax is in irregular angular or subglobular pieces from the size of a pea to that of a walnut, red-brown or yellowish-brown, friable, breaking with a flat somewhat waxy fracture, and frequently with vegetable fragments adhering. It has a strong, unpleasant odor, a balsamic bitter taste, yields with water a yellowish emulsion, and when heated softens and exhales a rather alliaceous odor. An inferior quality comes in larger irregular masses, which contain many impurities and are of a less bitter taste.

Composition.—According to Pelletier, opopanax contains 42 per cent. resin, 33.4 per cent. gum, besides volatile oil, a little wax, starch, etc.

Allied Gum-Resins.—SAGAPENUM, obtained from a Persian species of *Ferula*, is met with in yellowish-brown somewhat translucent small tears, and is frequently agglutinated to larger pieces, of a bitter acid taste and a faint alliaceous odor, which becomes prominent on heating. Cake sagapenum is soft, adhesive, brown, nearly free from tears, mixed with foreign matters. A mixture of galbanum and asafetida is sometimes sold in place of sagapenum. Pelletier and Brandes found in sagapenum 50 to 54 per cent. of resin, 32 per cent. gum, with small quantities of volatile oil, bassorin, etc.

GUMMIFERINA HEDERÆ, *Ivy gum*, is in the Levant and Southern Europe obtained from the common ivy, *Hedera Helix*, *Linneé* (nat. ord. Araliaceæ). It is in irregular yellowish or reddish-brown pieces, translucent on the edges, with a garnet-red color, of a slightly bitter and some-

what acrid taste, and when heated of an agreeable balsamic odor. Pelletier found in a sample nearly 70 per cent. of wood-fibre.

Medical Action and Uses.—Opopanax ("the all-healing juice") is one of the numerous gum-resins, including galbanum and ammoniac, which were anciently most esteemed. Galen speaks of it and of the root-bark of the plant as stimulating and cleansing when applied to ulcers, and of the seeds as diuretic. Dioscorides describes its internal uses in fever and ague, pleurisy, cough, dysury, and amenorrhœa, and its topical applications in sprains, headache, gout, toothache, and carbuncle. Arabian writers advise it in nervous exhaustion, for promoting the expulsion of the dead fœtus, for paralysis, and for inflammation of the eyes. In modern times it has been used, like ammoniac, for chronic bronchitis with profuse secretion, and externally in stimulating plasters, but is now very seldom employed. The dose may be stated at from 20 to 30 grains (Gm. 1.30–2).

Sagapenum was anciently used for the purposes to which asafetida and galbanum were also applied—i. e. to the cure of chronic bronchitis and other chronic catarrhs, menstrual disorders, hysteria, etc. The gum of *Hedera helix* was held to be acrid and astringent, and was employed topically for the relief of local pains and the moderation of profluvia, the healing of ulcers, etc. Griffiths states that some species of *Silphium* afford a fragrant bitter gum which is stimulant and aromatic; and Porcher refers to *S. laciniatum*, s. *gummiferum*, as having been used for asthma in horses, and to *S. perfoliatum* as tonic, diaphoretic, etc. In France a species of *Silphium* has been credited with the cure of phthisis, but doubtless the disease which it benefited was chronic bronchitis.

ORIGANUM, U. S.—ORIGANUM.

Origan, Marjolaine sauvage, Fr.; Dosten, Wilder Majoran (Meiran), G.

Origanum vulgare, Linné. Bentley and Trimen, Med. Plants, 204.

Nat. Ord.—Labiatae, Satureieae.

Origin and Description.—*Origanum*, or *wild marjoram*, is a perennial herb growing in dry soil throughout a large portion of Asia, Europe, and Northern Africa. It has been introduced into the United States, where in some places it is now quite common. The stem is about 2 feet (60 Cm.) high, quadrangular, often purplish, branched above. The leaves are opposite, petiolate, roundish ovate, obtuse, entire, or slightly toothed, hairy on the veins beneath, and pellucid punctate. The flowers are terminal on the branches, forming a corymbose panicle, have a purple, ovate bell-shaped and five-toothed calyx, a purplish somewhat two-lipped corolla, and four didynamous exerted stamens. The herb has a strong aromatic, marjoram-like odor and a warm aromatic and bitterish taste.

Constituents.—The herb contains volatile oil, a little tannin, bitter principle, etc.

OLEUM ORIGANI. U. S. 1870.—Oil of *origanum*, *E.*; *Essence d'origan, Fr.*; *Dostenöl, G.*—Raybaud obtained only 0.024 to 0.03 per cent. from the fresh plant, and Redet 2 per cent. from the recently-dried herb. Red oil of thyme (see **OLEUM THYMI**) is often sold in its place. It is pale-yellow and limpid, becoming thicker and brown-yellow on exposure, has a strong aromatic odor, and a warm, pungent, and slightly bitter taste. Its specific gravity varies between 0.87 and 0.91. It yields a turbid solution with 12 parts of alcohol specific gravity 0.85, fulminates when brought into contact with powdered iodine, acquires with sulphuric acid a dark blood-red color, and a deep-brown one with potassium bichromate and sulphuric acid (Zeller). The oil consists of a liquid and a solid portion, which have not been fully investigated. Kane (1838) ascribed to it the composition $(C_{10}H_{16})_5O$. According to Jahns (1881), it is left-rotating, and contains 0.1 per cent. of phenols.

Allied Plants.—**ORIGANUM MAJORANA**, *Linné*, s. *Majorana hortensis, Manch*; *Herba majoranæ*.—Sweet marjoram, *E.*; *Marjolaine, Fr.*; *Meiran, G.*—It is an annual herb, frequently cultivated for culinary purposes, and is indigenous to Western Asia and South-eastern Europe. The leaves are spatulate or oval, very obtuse, entire, gray-green, soft-hairy, and pellucid punctate. The flowers are aggregated in small heads and have a small whitish corolla. The plant is agreeably and pungently aromatic.

The volatile oil (*oleum majoranæ*) is thin, yellowish, of the specific gravity 0.89, boils above 163° C., is readily soluble in alcohol, has the aromatic odor of the herb, and, according to Beilstein and E. Wiegand (1882), contains a terpene boiling at 178° C. (352.4° F.) and forming a liquid compound with HCl; the fraction boiling between 200° and 220° C. (392° and 428° F.) has the composition $C_{15}H_{26}O$, and is not affected by metallic sodium.

An ointment of marjoram, *Unguentum majoranæ*, is occasionally employed; it is prepared by

softening 2 parts of the cut herb with 1 part of alcohol, then digesting with 10 parts of lard until the alcohol has evaporated, straining, and cooling.

ORIG. CRETICUM, *Linne*, indigenous to Southern Europe, has hairy ovate or nearly cordate and somewhat five-nerved, pungently aromatic leaves, and whitish flowers. In Europe the volatile oil is distilled from it, and is used like allied oils. The volatile oil of Orig. hirtum, *Link*, which is often sold in place of it, consists, according to Jahns (1879), of 50 to 60 per cent. of *carvacrol* and of several terpenes, besides a volatile acid and a small quantity of a phenol which becomes violet-colored with ferric chloride.

ORIG. DICTAMNUS, *Linne*, is found in the Levant, has woolly-tomentose, obtusely quadrangular branches, roundish-ovate tomentose leaves, partly purple-colored bracts, and a dark-purplish corolla. It is pungently aromatic.

Medical Action and Uses.—*Wild marjoram* has been applied in fomentations and poultices for the relief of local pains in the same manner as numerous other plants containing an aromatic volatile oil. *Sweet marjoram* is chiefly used as a condiment in cooking, to diminish, by its excitant qualities, the indigestibility of pork, goose, and other fatty food. It is sometimes employed in warm infusion to promote the eruption in exanthematous fevers, allay *colic*, *dysmenorrhœal pains*, etc., and the fresh bruised herb is applied as a cataplasm to assuage local pains. The infusion may be made with an ounce of the herb to a pint of water (Gm. 30 to Gm. 500). Oil of *origanum* is applied locally as an anæsthetic to relieve the pain of *carious teeth*, *neuralgia*, etc. It forms an efficient ingredient of liniments for *muscular rheumatism*, *contusions*, etc. It may be prescribed internally in doses of from 5 to 10 drops (Gm. 0.30–0.60).

OS.—BONE.

Os, Fr.; *Knochen*, G.

Description.—Bones form the skeleton of the vertebrate animals, and consist of a dense organic tissue which is filled with a calcareous deposit. They are white, externally smooth, insoluble in water, partly soluble in acids, leaving a gelatinous mass behind, and when heated are partly decomposed, an empyreumatic animal odor being given off and a porous charcoal left. (See CARBO ANIMALIS, p. 383.) On continuing the heat in contact with air, the organic matter is entirely consumed and a white earthy residue remains.

Composition.—The organic portion of bones, which is left undissolved on treatment with hydrochloric acid, has been called *ossein*, and on continued boiling with water is converted into gelatin (see page 724). The inorganic portion varies in different bones of the same individual, in the bones of different species, and in different layers of the same bone; it is smaller in the inner layers, amounting sometimes to 40 per cent., and in the outer layers it may reach 67 per cent. The ash contains phosphate (usually about 57 per cent. of the bones) and carbonate (about 5 to 10 per cent.) of calcium, phosphate of magnesium (1.1 to 2.7 per cent.), fluoride of calcium (nearly 1 per cent.), and traces of silica, iron, manganese, and probably also sodium chloride. *Æby* (1874) considers the principal inorganic constituents of bones to be united to a chemical compound having the formula $3(\text{Ca}_3\text{2PO}_4) \cdot \text{CaCO}_3$, probably united with water and mixed with calcium carbonate. *Tröy*, including the fossil kind, has the composition $6(\text{Ca}_3\text{2PO}_4) \cdot \text{Ca}_2\text{HO} \cdot \text{CaCO}_3 \cdot 4\text{H}_2\text{O}$. When old bones free from organic matter are dried at 200° C. (392° F.), the residue on being moistened with water becomes warm and increases to its original weight again. Above 250° C. (482° F.) more water and carbonic acid are given off.

When ground bones are treated with about 50 per cent. of their weight of sulphuric acid a mixture is obtained which is largely used as manure under the name of *superphosphate of lime*, containing, besides the organic matter of the bones, about 50 per cent. of calcium sulphate, 22 or 23 per cent. of acid calcium phosphate, and small quantities of magnesium compounds. On exposing such a mixture in thin layers to a current of crude illuminating gas the latter is deprived of ammonia, which combines with the superphosphate to the extent of about 10 per cent., forming phosphate and sulphate of ammonium. The product of this *dry ammonia process* for gas purification is considered to be more valuable as a fertilizer than the superphosphate of lime.

Pharmaceutical Uses.—OS USTUM, *Br*. Bone-ash is the inorganic residue left on burning bones to whiteness, and consists principally of phosphate of calcium, with about 10 per cent. of carbonate of calcium and a little calcium fluoride and magnesium phosphate. It is used in the manufacture of glacial phosphoric acid and in preparing Calc. phosphas and Sod. phosphas, *U. S.*, *Br*.

OXALIS.—WOOD-SORREL.

Alléluia, Surelle, Pain de coucou, Fr.; Sauerklee, Hasenklee, G.

Nat. Ord.—Geraniaceæ, Oxalidææ.

Description.—The following species indigenous to North America and Europe have been used:

O. ACETOSELLA, Linné. The plant has a thin, thread-like rhizome, which near the ascending apex is furnished with a number of crowded reddish fleshy scales and fine brown radicles. The leaves rise upon petioles about $2\frac{1}{2}$ inches (38 Mm.) long, and have three triangular-obcordate entire leaflets $\frac{1}{2}$ inch (12 Mm.) long. The scapes are longer than the petioles, and bear a single white, red-veined flower with ten alternately short stamens. The capsule is five-angled and five-celled, each cell containing two seeds.

O. STRICTA, Linné. This is an annual herb with a stem 6 to 12 inches (15 to 30 Cm.) high, producing subterranean shoots which survive the winter. The leaves are petiolate, with three obcordate leaflets, and the flowers yellow, forming a small umbel on peduncles longer than the petioles.

Several species, mostly acaulescent and bulbous, and bearing white, purple, or yellow flowers, are seen in cultivation. All are inodorous or nearly so, and have a pleasant acidulous taste.

Constituents.—Besides the principles common to most herbs, these plants contain acid potassium oxalate (see p. 79).

Medical Action and Uses.—Wood-sorrel and yellow wood-sorrel depend for their medicinal virtues upon the oxalate of potassium they contain. They have been long considered anti-scorbutic, diuretic, and sedative in febrile conditions. In the last case an infusion of the plant forms an agreeable acidulous drink. Sorrel may be eaten as a salad mixed with lettuce, water-cress, etc. In *scorbutus, purpura*, and some cases of *venal intermittent fever* it is reported to have been curative. In Europe it is commonly eaten as a dressing for insipid meats, such as veal and sweetbread, and it is stated that its habitual use in this way has led to the formation of urinary calculi of oxalate of lime. Externally, the bruised leaves are sometimes applied to cleanse and stimulate foul *ulcers*.

OXYGENIUM.—OXYGEN.

Oxygène, Fr.; Oxygen, Sauerstoff, G.

Symbol O. Atomicity bivalent. Atomic weight 16.

Oxygen was discovered by Priestley (1774) and Scheele (1775). It constitutes about one-fifth of the volume of atmospheric air, the remainder being nitrogen, with a small proportion of carbonic acid gas. Eight-ninths of the weight of water and one-half the weight of many minerals consist of oxygen, and it is estimated that at least one-third the weight of the solid crust of the earth is made up of this element, which is the most abundant of all.

Preparation.—Oxygen may be obtained by exposing binoxide of manganese, oxide of mercury, or some other metallic oxide to a strong heat, but it is most conveniently prepared by heating a mixture of 4 or 5 parts of chlorate of potassium with 1 part of binoxide of manganese. At a low red heat the chlorate is completely decomposed into oxygen and potassium chloride, which remains mixed with the manganese; the latter, not being altered, may be recovered by dissolving the potassium chloride in water; $KClO_3$ yields $KCl + O_3$. Care should be taken that black sulphide of antimony be not used in place of binoxide of manganese, and that the mixture be free from organic compounds, since a violent explosion would take place on the application of heat.

Properties.—Oxygen is a colorless and inodorous gas having the density 1.1056 as compared with air; 1 liter of it at $0^\circ C.$ ($32^\circ F.$) and a barometric pressure of 0.76 meter weighs 1.43 Gm. L. Cailletet and R. Pictet (December, 1877) succeeded in reducing it to the liquid state, when it has the density 1.0. It is slightly soluble in water and alcohol, and combines with all other elements, perhaps with the sole exception of fluorine. These compounds are called *oxides*, and the act of combination *oxidation*, and when attended with heat and light it is termed *combustion*.

By the action of electricity upon oxygen, or by the slow oxidation of phosphorus in moist air, and under various other circumstances, oxygen is converted into *ozone*, which is a gas as usually obtained colorless, but, according to Hautefeuille and Chappuis (1880), of a deep-blue color if sufficiently concentrated, and under a pressure of 125 atmospheres forms indigo-blue drops, which after the removal of pressure evaporate slowly. It has

a peculiar odor, somewhat resembling that of chlorine, is a powerful oxidizing agent, bleaches indigo solution, and liberates iodine from potassium iodide; paper dipped in thin starch-paste containing potassium iodide is turned blue by ozonized air, and is a delicate test for the presence of ozone. This body has not been obtained free from oxygen; it is regarded simply as a modification of oxygen, its formula being O_2O , indicating that 3 vols. have been condensed into 2; its spec. gravity is one-half greater than that of oxygen. It is nearly insoluble in water (see also page 799).

Physiological Action.—It was taken for granted that oxygen could be introduced by the lungs as readily as food is carried into the system through the stomach, and that by its means all the organic operations of the economy could be aroused to an increased activity. Experimenters graphically described the enlivening influence of this increased supply of "vital air" upon the sensations and the organic functions, and were apt at explaining how it not only must, but actually did, cure some of the gravest of diseases. But it was pointed out by Dr. A. H. Smith, and then by Dr. B. W. Richardson, that no more than a certain proportion of oxygen, such as exists in the atmosphere, can be absorbed by the lungs. Their results were subsequently (1875) confirmed by Buchheim, who concluded that "henceforth we must abandon the notion that the course of diseases can be modified by increasing the amount of oxygen in the blood." It should be remembered that Richardson and others have shown (*Lancet*, Nov. 1878, p. 749) that oxygen inhaled in large quantities is so far from being a stimulant that it relaxes and debilitates the system, and, in fact, induces narcotism. According to Hayem, on the other hand, the inhalation of from 50 to 100 quarts a day of oxygen, more or less diluted with atmospheric air, stimulates the appetite, raises the temperature slightly, quickens the pulse, and increases the weight. It temporarily augments "the hæmatoblasts and the red corpuscles," and the proportion of hæmoglobin in the latter, but it restores neither their normal size nor form (*Archives gén.*, June, 1881, p. 745).

Medical Uses.—A critical examination of the reports of *pulmonary consumption* treated by oxygen proves that no ground exists for the belief that the disease is either curable or benefited by this gas; the same may be said of *diabetes*, in which it transiently diminishes the diuresis and the proportion of sugar; of *albuminuria*, in which it similarly reduces the albumen; and also of *hydrophobia*, in spite of some cases which are alleged to have recovered under its use. In chronic *bronchitis* and other affections of the respiratory organs attended with symptoms of *asphyxia* the inhalation of oxygen has certainly appeared to prolong, and even to save, life. This has been demonstrated in *asphyxia* from emphysema with bronchitis, in laryngitis of various forms, in compression of the lungs by the gravid uterus, in *opiate narcotism*, in poisoning by charcoal fumes or by illuminating or *privy* gas, and in similar conditions. A case is recorded in which it seems to have saved the life of a child poisoned by a very large dose of carbolic acid (*Bull. de thérap.*, cv. 417). Its most striking benefits are observed when the gas is inhaled by *dyspeptic chlorotic* patients. It revives the appetite, quickens the digestion, and arrests vomiting if present, and consequently increases the excretion of urea. But this improvement is not permanent unless iron is used as supplementary to the oxygen (*Bull. de thérap.*, xcviii. 427). In traumatic *tetanus* the inhalation of oxygen is said to have caused profuse diaphoresis and muscular relaxation (Richardson). In some cases of *vomiting* during pregnancy this treatment has arrested the symptom when all other measures had failed. (For a detailed account of oxygen as a medicine see STILLE, *Therapeutics*, etc., 4th ed., i. 703.) If possible, the oxygen should be inhaled from a reservoir or bag containing it through a tube with a suitable stopcock and valves, in the same manner as nitrous oxide gas.

OXYMEL, Br.—OXYMEL.

Oxymel simplex, *Mel acetatum*.—*Oxymel* (*Oxymellite*) *simple*, *Acétomel*, Fr.; *Sauerhonig*, G.

Preparation.—Take of Clarified Honey 40 ounces; Acetic Acid and Distilled Water, each 5 fluidounces. Liquefy the honey by heat, and mix with it the acetic acid and water.—Br.

The French Codex orders 1 part of white wine vinegar to be mixed with 4 parts of virgin honey, and the mixture to be concentrated and clarified with paper pulp. The German Pharmacopœia of 1872 directed the mixing of 40 parts of clarified honey with 1 part of acetic acid spec. grav. 1.040; this is certainly the simplest process.

Medical Action and Uses.—This is an official form of the popular mixture of honey and vinegar, which is generally used as a gargle in *sore throat*. It may be pre-

scribed as an excipient for various expectorant medicines, and particularly for squill and ipecacuanha in the form of syrup.

OXYMEL SCILLÆ, Br., P. G.—OXYMEL OF SQUILL.

Oxymel scilliticum.—*Oxymel scillitique*, Fr.; *Meerzwiebelhonig*, G.

Preparation.—Take of Vinegar of Squill 1 pint; Clarified Honey 2 pounds. Mix and evaporate by a water-bath until the product when cold shall have the specific gravity 1.32.—*Br.* The process of the P. G. is practically identical with this. Vinegar of squill 1 part, honey 4 parts; clarify with paper pulp and evaporate to the density 1.26.—*P. Cod.*

Medical Action and Uses.—Oxymel of squill has the medicinal virtues of syrup of squill, neither more nor less. Honey is superior to syrup as a local application to the throat, but there is no known difference between them in their action upon the air-passages. Like the syrup of squill, the oxymel may be prescribed in *catarrhal affections* of the respiratory mucous membrane, and in young children as an emetic in spasmodic croup. The dose, as an expectorant, is for adults a teaspoonful (Gm. 4); for infants, from 5 to 20 drops (Gm. 0.30–1.30). As an emetic for children a teaspoonful (Gm. 4) may be given at short intervals.

PÆONIA.—PEONY.

Pivoine, Fr.; *Gichtrose*, *Pfingstrose*, G.

Pæonia officinalis, Linné.

Nat. Ord.—Ranunculacææ, Pæoniææ.

Description.—Peony is a perennial herb from Southern Europe, which is frequently cultivated for ornament. It has an oblique many-headed root-stock 6 or 9 inches (15–23 Cm.) in length, with numerous at first fibrous roots, which afterward enlarge and become fusiform, dark-brown, internally white and mealy, resembling elongated tubers, about 2 or 3 inches (5–8 Cm.) long, and $\frac{1}{2}$ inch (12 Mm.) thick. In commerce these are generally peeled, are whitish or purplish, and have near the circumference narrow yellow wood-wedges. The branched stem is about 2 feet (60 Cm.) high, smooth, with large, twice or thrice pinnately dissected and cleft green smooth leaves, and large terminal flowers, having five sepals, five to eight petals, numerous stamens, and two to five ovaries. The petals are obovate, entire or crenate, $1\frac{1}{2}$ inches (18 Mm.) long, dark-red, purple or rose-red, after drying inodorous, and have a sweetish astringent taste. The seeds are nearly globular, $\frac{1}{8}$ to $\frac{1}{4}$ inch (3–4 Mm.) in diameter, black, glossy, and smooth, inodorous, and contain a yellowish oily albumen and a small embryo. The tuberous roots, petals, and seeds have been used.

Constituents.—Wiggers obtained from the fresh root a distillate having the odor of bitter almonds and acquiring a blood-red color by ferric chloride; separated by means of ether, the volatile oil had a pale-yellow color. The analysis of the fresh root by Morin proved the presence of starch, sugar, fat, malates, oxalates, and phosphates, a little tannin, etc. The root of *Pæonia peregrina*, Miller, yielded to Dragendorff and Mandelin (1879) 4.1 to 5.4 per cent. of ash, some sugar, starch, gummy matter, and small quantities of tannin, resin, fat, etc., while the seeds contain 23.6 per cent. of fixed oil, various coloring matters, etc., and a crystalline body which in the ripe seeds appears to be changed to an indifferent and an acid resin. The root of the Japanese species, *Pæonia Moutan*, Simson, according to Jagi (1878), contains a crystalline substance closely related to capric acid; it melts at 45° C. (113° F), sublimes at a higher temperature, and is easily soluble in ether and alcohol.

Medical Action and Uses.—In the ages of medical faith the virtues of this plant were highly esteemed. Galen described its acrid qualities and emmenagogue virtues, and its astringency also, which rendered it useful in diarrhœa. A superstition prevailed in his time that peony-root enclosed in a bag and hung around a child's neck both prevented epileptic attacks and cured them, and this belief is not yet extinct among the peasantry of Europe. They also believe that the same amulet, or rather one made with the seeds, worn on the arm, will prevent the dangers of dentition and promote menstruation. That the plant is not inert is abundantly proved; its very odor has caused syncope; in one case an infusion of it brought on an attack of convulsions, and in another it produced headache, ringing in the ears, confusion of sight, violent colic, and vomiting. Modern observation has neither confirmed nor condemned the ancient opinions concerning it; and although some have reported favorably of it in *epilepsy*,

chorea, and *whooping cough*, the evidence in favor of its efficacy is very slender indeed. The powdered root may be prescribed in doses of from 15 to 60 grains (Gm. 1–4), or an infusion made with from half an ounce to an ounce of the bruised root in a pint of water (Gm. 16–32 in Gm. 500).

PANAX.—GINSENG.

The root of *Panax quinquefolium*, *Linné*, s. *Aralia quinquefolia*, *Gray*.

Nat. Ord.—*Araliaceæ*.

Origin.—North American ginseng is a perennial herb growing in rich and cool woods. The stem is a foot (30 Cm.) high, and bears at the summit three large palmately five-foliate leaves, with long-stalked, obovate-oblong, pointed, doubly serrate leaflets. The greenish-white flowers are in a terminal subglobular umbel, and produce globular scarlet-red two-celled and two-seeded berries.

Description.—The root is fusiform, 2 to 3 inches (5–8 Cm.) long, with a rounded head, closely annulate, and with few wrinkles above, dividing below into two, or occasionally three, branches of even size. The branches are not, or are but slightly, annulate, and are longitudinally wrinkled. The root is externally of a light brownish-yellow color, internally white, breaks with a short and mealy fracture, and has a faint sweetish odor and a sweet slightly aromatic taste. The transverse section shows a thick bark, with numerous scattered brown-red resin-cells, and in older roots is radially striate from the bast-wedges; it is separated by a brown cambium-line from the central portion, which consists of linear wedge-shaped yellowish wood-bundles and broad medullary rays.

Panax Schinseng, *Nees*, the *Chinese ginseng*, has a larger root, 4 to 6 inches (10–15 Cm.) long, darker in color, and near the head usually with two lateral branches, otherwise resembling the preceding.

Constituents.—Besides starch, gum, albumen, and resin. S. S. Garrigues (1854) isolated a sweet principle, *panaquilon*, $C_{12}H_{25}O_9$, by adding to the syrupy infusion a concentrated solution of sodium sulphate and dissolving the precipitate in alcohol. It is yellow, amorphous, sweet, insoluble in ether, and precipitated by tannin. Concentrated sulphuric acid dissolves it with a purple-red color, converting it at the same time into *panacon*, $C_{11}H_{19}O_4$, which is white, tasteless, and insoluble in water and ether, but soluble in alcohol.

Medical Action and Uses.—It is unsettled whether or not the American and Chinese species of ginseng are identical. It is at least certain that while the former is only agreeable in taste, and perhaps useful as a mild stomachic, the latter enjoys in its native country the reputation of a panacea, and especially of being aphrodisiac. The affections for whose cure it is most esteemed are such as are usually treated by aromatic stimulants, including *dyspepsia*, *vomiting*, and *nerve disorder*. It is used as a masti-catory, and also in infusion.

PANCREATINUM.—PANCREATIN.

Origin.—The *pancreas* is a gland which is deeply seated in the abdomen and secretes the *pancreatic juice*, containing the proteid *pancreatin*, to which it owes the property of emulsifying and decomposing fats into glycerin and acid and of converting starch into sugar. The pancreatic juice is a colorless, clear, somewhat viscid liquid, of an alkaline reaction, without odor and of an insipid somewhat saline taste; it contains, besides the ferment, nearly 1 per cent. of mineral salts, a trace of fat and of organic matters soluble in water.

Preparation.—Prof. Scheffer (1875) recommended the following process: Fresh and finely-chopped beef pancreas is macerated for a day in water acidulated with a little hydrochloric acid; the maceration is repeated with water; the strained liquids are filtered, neutralized with calcium carbonate, again filtered, and mixed with an equal volume of 95 per cent. alcohol; the precipitate is washed with dilute alcohol, pressed between bibulous paper, and dried at the ordinary temperature.

Properties.—Thus prepared, it is a transparent, brittle, yellow mass, which dissolves in water slowly, but almost entirely, leaving, when prepared in cold water, only a trace of insoluble matter. The solution is clear, pale-yellowish, neutral, and produces white precipitates on heating and on being mixed with alcohol. Hydrochloric acid likewise precipitates it, but not a saturated neutral solution of table-salt.

Composition.—Like other proteids, pancreatin consists of C, H, N, O, and a little S (see VITELLUS), and belongs to the soluble ferments, designated by Kuehne as

enzymes. Bernard assumed the presence in the pancreatic liquid of two ferments, and in 1878 Defresne announced the isolation of even three—namely, *mylopsin*, which digests albumen; *amyllopsin*, which saccharifies starch; and *steapsin*, which decomposes fats. The first of these, or proteolytic enzyme, has been termed *trypsin*, and the second, or amylolytic enzyme, as *pancreatic diastase*, by W. Roberts (1881), who found the diastatic value of pancreatic extracts to be uniform between 30° and 45° C., to be less below and above these temperatures, and to cease between 65° and 70° C. On the other hand, the proteolytic activity gradually increases in energy up to 60° C., then falls rapidly, and is finally arrested between 75° and 80° C. It may be valued by determining how many cubic centimeters of milk, after digestion with 1 Ccm. of pancreatic extract at 40° C. for 5 minutes, will be changed so as to be distinctly curdled on boiling (the onset point); on prolonged digestion the property of curdling by heat will abruptly disappear (the vanishing point). Quantity and time are inversely related as far as the onset point is concerned, only provided the time does not exceed 8 or 10 minutes: if the test be performed at 20° C., sufficiently accurate results are obtained by multiplying with 3.5. The proteolytic value of the pancreatic juice of the pig was found to vary between 64 and 83; of the ox, between 42 and 83; and of the sheep, between 28 and 125.

The amylolytic action is measured by determining the number of cubic centimeters of standard mucilage of starch, containing 1 per cent of the latter, which can be brought to the achromic point (of not being colored blue by iodine) by 1 Ccm. of pancreatic extract at 40° C. in 5 minutes. In testing, 10 Ccm. of starch solution are diluted with 90 Ccm. of water, and from .02 to .20 Ccm. of the pancreatic liquid may be employed: in the action of the ferment quantity and time are in inverse proportion, unless largely diluted. The diastatic value of the pancreatic liquid of the pig is 100; of the ox, 11; of the sheep, 10; of filtered human saliva, 10 to 17; and of malt diastase, 4 to 5, increasing to 10 at 60° C.

Medical Action and Uses.—Pancreatic juice has an alkaline reaction, converts starch into sugar, and decomposes fat into fatty acids and glycerin. It also forms with albumen an alkaline solution. The latter action, which is ascribed to pancreatine, and forms the ground of its utility in disease, is not interfered with by the presence of the acid secretions of the stomach. During the first years of life, when the food consists chiefly of milk and farinacea, a state of *dyspepsia* frequently arises which often leads to marasmus, and which is not traceable to any organic lesions of the stomach or auxiliary viscera. In this it is claimed that pancreatic emulsion speedily restores the digestive function to its normal condition, and, through improved nutrition, renews the health. "Defresne has recommended pancreatine in *phthisical* cases where the patient is unable to digest or assimilate cod-liver oil; in cases of *jaundice* in which fat is badly digested; in cases of *dyspepsia* in which the patient experiences abdominal pains, vomiting, diarrhoea, and flatulence several hours after meals; and, speaking generally, in those cases of disturbances of digestion in which fats and starches are badly assimilated and where pepsine is found to be useless" (*Practitioner*, xx, 454). Hence it is reported to be serviceable in such diseases as are more or less maintained by the imperfect digestion of albuminous food, including *rachitis*, *scrofula*, *diabetes*, and *fatty diarrhoea*, *anæmia*, *chlorosis*, *leukæmia*, *pernicious anæmia*, and the early stage of *tuberculosis*. It has also been profitably employed during *convalescence* from acute wasting diseases (Loebisch). In all of these cases it may be administered by the mouth. It was, however, originally introduced into medicine by Leube in 1874 as an efficient means of nourishing by the rectum when the stomach could not retain or digest food. Such were cases of *gastric atony* produced by protracted illness; of *gastric irritability* caused by disease of the stomach itself or by disorders of its nervous system leading to the rejection of food; of cases also of *stricture of the œsophagus* or compression of it by tumors; and, finally, cases of *gastric hæmorrhage* in which the introduction of food into the organ might be attended with danger. All other forms of nutritive enemata had failed of their purpose, both because they were, or soon became, mechanically irritating, and because they were not of such a nature as to be absorbed, or to subserve the purposes of nutrition had their absorption been practicable. The first of these objections does not apply to pancreatic emulsions, probably because their reaction, like that of the rectum, is alkaline.

Leube's directions for preparing the enemata are as follows: Take a piece of lean beef and scrape or grate it until it is reduced to a fine pulp. For one injection from 5 to 10 ounces (Gm. 150–300) of it should be mixed with an equal quantity of finely-hashed pancreas and thoroughly pounded in a mortar or crushed in a bowl with a spoon, with the gradual addition of about 5 ounces (Gm. 150) of lukewarm water until the mixture

is of the consistence of pap. If it is desired to administer fat, it may be added in the proportion of about one-sixth of the meat. To inject this mixture a syringe with a much larger nozzle than usual is required. If the enema is judiciously introduced, the whole of it will be retained, and, according to Leube, will penetrate even to the transverse colon. He refers to cases in which, after from 12 to 36 hours, the stool was feculent, without any trace of the emulsion. He further advises that, as the pancreas readily becomes stale in warm weather, it should be preserved by mixing its pulp thoroughly with glycerin.

A number of cases have been published in which pancreatic enemata were either the means of saving life permanently, or in which, owing to the incurable nature of the disease, they prolonged life far beyond the term when it must otherwise have terminated. To the latter category necessarily belong all cases of organic stricture of the digestive canal; to the former, cases of simple ulcer of the stomach and nervous vomiting.

The preparation of the pancreas for administration by the mouth differs from that just described. According to Engesser, the pancreas of the hog, sheep, or ox should be used, that of the hog being preferable. After being finely minced it is forced through a hair sieve. The semi-liquid product may then be directly mixed with the food, or may, after the addition of a little salt, be preserved in a cool place in a properly-covered jar. For immediate use the watery infusion of pancreas may be employed, although it is less efficient than the gland substance. It is also less repulsive in appearance than the emulsion, and its taste is not unlike the cold prepared extract of beef. Pancreatic pulp may be given in bolus, in wafers, or mixed with the food, and in the dose of about a dessertspoonful at each meal. Care must be taken not to mix it with hot food (113° F. = 45° C.). Various expedients have been suggested for concealing the unpleasant taste and smell of the emulsion, and for securing its thorough and equable mixture with the food, but they must generally be left to the ingenuity of the physician or patient. It need only be added that the food should not be taken very hot, especially in the form of soup, nor very highly seasoned, nor with much or strong wine. On the whole, it must be admitted that pancreatic emulsions given by the mouth are less valuable than was anticipated, probably because their active constituents are neutralized by the acid contents of the stomach.

PAPAVERIS CAPSULÆ, *Br.*—POPPY-CAPSULES.

Fructus s. Capita papaveris immaturi, P. G.; *Papaver*, U. S. 1870.—*Capsules (Têtes) de pavots*, Fr.; *Mohnkapseln*, *Mohnköpfe*, G.

The nearly-ripe capsules of *Papaver somniferum*, *Linné*. Bentley and Trimen, *Med. Plants*, 18.

Nat. Ord.—Papaveraceæ.

Origin.—The poppy is an annual herb, and is most likely indigenous to Western Asia and South-eastern Europe, where it is found wild in fields and waste places. It is

FIG. 203.

FIG. 202.

FIG. 204.

Black.

Poppy-capsules and seeds: a, natural size; b, magnified.

White.

Depressed.

frequently cultivated in gardens for ornament, and very extensively in several countries for the production of opium (see OPIUM). The stem is 3 to 5 feet (0.9–1.5 M.) high;

the leaves are alternate, 5 to 10 inches (12–25 Cm.) long, oval-oblong, sessile, and the upper ones clasping, irregularly dentate, frequently cleft or nearly pinnatifid, rather thick, smooth, and glaucous. The flowers terminate the branches, are about 4 inches (10 Cm.) broad, and have two oval blunt caducous sepals, and four broad roundish petals varying in color from white to violet and dark-purple, with a darker spot near the base. The stamens are numerous, and inserted beneath the subglobular ovary, which is crowned by the peltate radiating stigma. The wild form, *Papaver setigerum*, *De Candolle*, has acute teeth, prolonged into a stiff bristle. The white flowering variety, *Pap. officinale*, *Gmelin*, has white seeds, and its capsules are alone recognized by pharmacopœias.

Description.—Poppy-capsules vary in shape and size according to the variety of the plant from which they have been obtained. The black poppy usually has rather small capsules, which are globular-ovate, about $1\frac{1}{2}$ inches (37 Mm.) in diameter, broadest near the base, and dehiscent by small apertures forming underneath the stigma. The capsules of the white poppy are mostly larger, indehiscent, and more variable, occasionally depressed and much broader than high, but usually oblong, or in some varieties much elongated and narrowed toward the base. The sessile and peltate stigma is formed of from eight to twenty rays, and a similar number of longitudinal striæ, marking the sutures, are observed upon the immature capsule, which is smooth, and underneath the epidermis consists of loose parenchyma with a circle of thin fibro-vascular bundles and larger laticiferous vessels. The capsule is one-celled, but internally is furnished with placentas equal in number to the lobes of the stigma and projecting into the interior, forming incomplete partitions. In the fresh state it has a narcotic odor; after drying it is nearly inodorous; its taste is bitter.

SEMIN PAPAVERIS, P. G.—Poppy-seed, Maw-seed, *E.*; Semences (Grains) de pavot, *Fr.*; Mohnsamen, Magsamen, *G.*—The seeds are very numerous, quite small, about $\frac{1}{20}$ inch (1.2 Mm.) long, reniform in shape, white, blackish, or bluish, finely netted-veined, and contain an oily albumen enclosing a curved embryo. They are inodorous, and have a bland oily and scarcely bitterish taste. Only white poppy-seeds are medicinally employed. About 700 pounds of poppy-capsules and 425,000 pounds of poppy-seed were imported in 1882.

Constituents.—1. **THE CAPSULES.** Winckler (1837), Merck, and others have demonstrated the presence of *morphine* in ripe poppy-capsules; the former chemist obtained as much as 2 per cent. of this alkaloid, and likewise *narcotine* and *narcaine*. Groves (1854) found also another alkaloid, which was probably *codeine*. A. Buchner obtained an alkaloid which differed from morphine, and other chemists were unable to find the latter. Deschamps (1864) isolated an alkaloid, and silky needles of a nitrogenous body called *papaverin*, which is said to have an acid reaction; the alkaloid *papaverosine* forms colorless, nearly tasteless prisms, is soluble in alcohol, ether, chloroform, and benzol, has a slight alkaline reaction, and with sulphuric acid assumes a violet color, which on warming becomes red, and with nitric acid orange-red. Hesse (1866) obtained *rhaudine* from ripe poppy-capsules. Besides meconic acid, which could not be detected by several chemists, citric and tartaric acids were found by Deschamps. The capsules contain considerable mucilage. The waxy coating of the epidermis is scraped off in the preparation of opium, and forms a constituent of the latter. Examined by Hesse (1870), it yielded a colorless compound insoluble in chloroform, crystallizing in prisms, and melting above 100° C. (212° F.); the portion soluble in boiling chloroform consists of *corylcerotate*, $C_{27}H_{55}.C_{27}H_{53}O_2$, which crystallizes in silky scales, melts at 82.5° C. (180.5° F.), and congeals in crystals at 80° C. (176° F.); and of *corylpalmate*, $C_{32}H_{55}.C_{16}H_{31}O_2$, which forms crystalline warts melting at 76° C. (168.8° F.).

2. **THE SEEDS.** Sacc (1849) obtained from white poppy-seeds nearly 55 per cent. of fixed oil, 23 pectin, and 12.6 per cent. protein compounds. Accarie (1833) announced that he isolated 30 grains of morphine from 6 pounds of white seeds. The fixed oil (**OLEUM PAPAVERIS, P. G.**—Poppy-seed oil, *E.*; Huile de pavots, Huile d'œillette, *Fr.*; Mohnöl, *G.*) is pale-yellow, bland, limpid, of the density 0.92, congeals near -18° C. (0° F.), and on exposure becomes thick and hard. It is soluble in 25 parts of alcohol, freely soluble in ether, and yields when saponified 9.5 per cent. of glycerin.

Off. Prep.—Of the capsules: Decoct. papaveris, Extract. papaveris, Syrupus papaveris, *Br.*

Medical Uses.—Formerly decoctions of poppy-heads were much used internally, but such is no longer the case since preparations of opium of definite strength have become multiplied. Even for external use such decoctions have been almost entirely

supplanted by liquid opiates and plasters containing opium. The official retention of papaver seems unnecessary, unless for pharmaceutical purposes.

PARAFFINUM.—PARAFFIN.

Paraffinum durum and *Par. molle*, Br.; *Paraffinum liquidum* and *Par. solidum*, P. G.; *Ceresinum*.—*Paraffine*, Fr.; *Paraffin*, G.

Origin.—The paraffins are produced under various circumstances from fats and other organic compounds, but are chiefly obtained among the products resulting from the destructive distillation of many organic substances, especially cannel and boghead coal, and from bituminous shale. They are a natural constituent in varying proportions of the different kinds of petroleum, and solid paraffins are found native in Austria, Great Britain, the United States (Utah), and some other countries, constituting the minerals known as *earth-wax*, *fossil (mineral) wax*, and *ozokerite*.

Properties.—“Liquid paraffin is a clear oily liquid having a specific gravity of not less than 0.840, and boiling not below 360° C. (680° F.). Solid paraffin is a white micro-crystalline, inodorous mass, melting between 74° and 80° C. (163° and 176° F.). Both paraffins should be free from colored, fluorescing, and odorous compounds. When heated for a day with sulphuric acid by means of a water-bath, the paraffins should not become dark-colored, and the sulphuric acid should become only slightly brownish. Metallic sodium, treated in a similar manner, should retain its metallic lustre. Alcohol boiled with paraffin should not have an acid reaction.”—*P. G.*

Paraffin is insoluble in water, alkalies, and cold alcohols, but dissolves in volatile and fixed oils, ether, chloroform, benzol, and carbon bisulphide; the solubility is, however, influenced by the composition. The melting-point of commercial paraffin varies much. Obtained from the residuum of petroleum distillation, it is usually about 43° C. (109.4° F.), or somewhat higher; from peat, about 47° C. (116.6° F.); from ozokerite, about 60° C. (140° F.); from *Rangoon tar* of Burmah, about 62° C. (143.6° F.); and the mineral wax of Moldavia, known as *zietriskite*, melts between 85° and 90° C. (185°–194° F.), and is insoluble in ether. Hard paraffin, *Br.*, should melt between 43.3° and 62.8° C. (110°–145° F.).

Composition and Characters.—The general formula of the paraffins is the same as that of the lighter coal oils, C_nH_{2n+2} , but in their physical properties they differ from the latter in being at the ordinary temperature either solid, and frequently crystalline, or of a butyraceous consistence or liquid. Those which are liquid at the ordinary temperature are known in commerce as *paraffin oils*, while the name *paraffin* is retained for the solid products. They can be separated from one another only with great difficulty, but it is known that the different members of this homologous series increase in density, visciduity, and in boiling-point, and the solid paraffins also in melting-point and hardness, as the molecular weight increases. The paraffins, obtained in as pure a state as possible, show the following differences:

Nonane (Nonylhydride),	C_9H_{20} ,	boils near 138° C. = 280.4° F.,	spec. grav. .741
Decane (Decetylhydride),	$C_{10}H_{22}$,	“ 160 = 320	“ .757
Endecane (Undecylhydride),	$C_{11}H_{24}$,	“ 180 = 356	“ .766
Dodecane (Laurylhydride),	$C_{12}H_{26}$,	“ 200 = 392	“ .778
Tridecane (Cocylhydride),	$C_{13}H_{28}$,	“ 220 = 428	“ .796
Tetradecane (Myristylhydride),	$C_{14}H_{30}$,	“ 240 = 464	“ .809
Pentadecane (Benylhydride),	$C_{15}H_{32}$,	“ 260 = 500	“ .825

Galletly (1871) ascertained for paraffins—

Fusing at 32.0°	39.0°	40.5°	53.3°	58.0°	59.0°	80.0° C.,
the spec. grav. .8236	.8480	.8520	.9100	.9243	.9248	.9400

The solubility of paraffins in benzol decreases as the melting-point rises, the last one of the table being nearly insoluble therein.

Paraffins are not easily acted on by chemicals. By continued boiling with nitric acid the higher paraffins yield nitro-compounds and various acids. Boiling hydrochloric acid or contact with chlorine gas, ammonia, or potassa has no effect upon paraffin, but the lowest members of the series, which are gaseous at the ordinary temperature, yield substitution-products with chlorine.

In distilling paraffin, the heat to which the vapors are exposed influences the melting-point, and consequently the composition; at a red heat *naphthalin* is produced, and when paraffin is heated for some time in a sealed tube it is split into an olefin and a paraffin of a lower boiling-point.

Olefins are present among the products of dry distillation of organic substances, in

rock oils, mineral tars, etc. They have the formula C_nH_{2n} , and the so-called paraffin oils usually consist principally of olefins, particularly of *heptilene*, C_7H_{14} , which boils at $96^\circ C.$ ($205^\circ F.$). The olefins are readily polymerized by the action of sulphuric acid, zinc chloride, and other chemicals, and unite with the halogens, their hydro-acids, and with hypochlorous acid; by nascent hydrogen they are converted into paraffins.

J. L. Lemberger and A. W. Miller ascertained (1875) that crude paraffin oils may be deprived of their odor by filtering them through granulated animal charcoal. *Cosmoline*, *vaseline*, and other copyrighted preparations are paraffins containing olefins of the consistence of ointments. (See PETROLATUM.) The liquid paraffins are extensively employed for lubricating purposes, and are known in commerce as *lubricating oils* and *neutral oils*.

Medical Action and Uses.—A case of death in a boy from swallowing paraffin oil is reported (*Med. Times and Gaz.*, Nov. 1878, p. 631), but the symptoms are not detailed. A child two years old drank some of the oil, and fell into a state of collapse with drowsiness. There was neither vomiting nor diarrhœa. On the morrow the child was well (*Lancet*, 1880, vol. ii, p. 730). Soft paraffin and paraffin oils are much used in a pure state and in ointments as a dressing for *chilblains*, *excoriations*, *bruises*, *indolent ulcers*, and in some diseases of the skin, especially *eczema*, *psoriasis*, and *scabies*. As a substitute for various fatty substances, oils, lard, glycerin, and glycerite of starch, which are more or less irritating in cutaneous affections, Kaposi prefers petroleum or vaseline jelly, as being unirritating and having no tendency to become rancid, and employs an ointment composed of equal parts of lead plaster and vaseline, thoroughly incorporated by the aid of heat and scented with oil of bergamot. Galezowski recommends vaseline as the best excipient for yellow oxide of mercury, nitrate of silver, etc. in the treatment of *scrofulous affections of the eye*, chiefly *keratitis* and *conjunctivitis*. The lead plaster spoken of above is *Unguentum diachylon Hebræ*, and consists of simple litharge ointment melted with an equal quantity of olive or linseed oil. Solid paraffin, when mixed with glycerin or linseed oil, has been used with advantage in the same diseases (Purdon). Dubois is of the opinion that vaseline scented with otto of roses, when applied to the vagina during parturition, facilitates labor by relaxing the tissues; that it may be used with advantage to protect the hands of the obstetrician in vaginal explorations; and that it answers better than oil or soap to remove the smegma from the new-born child. It is said that vaseline used as an excipient for carbolic acid impairs or destroys the antiseptic qualities of the latter. But when the mixture is applied to a moist tissue the acid is dissolved out by the water of the part and exerts its special action. Mixed with an equal weight of honey and 10 grains of borax or of chlorate of potassium to the ounce, it is a useful application in *thrush*. Mixed with 10 grains of quinia to the ounce (Gm. 0.60 to Gm. 32), it quickly removes *ascarides of the rectum*; it is beneficial in the *ophthalmia* of the newborn child; cures the *coryza* of suckling children when applied with a brush to the interior of the nostrils; and effects a rapid healing of *intertrigo*.

PAREIRA, U. S.—PAREIRA.

Pareiræ radix, Br.—*Pareira brava*, E. Fr., G.; *Racine de butua*, Fr.; *Grieswurzel*, G.

The root of *Chondodendron tomentosum*, Ruiz et Pavon, s. *Cocculus Chondodendron*, De Candolle, s. *Cissampelos Abutua*, Vellozo, s. *Botryopsis platyphylla*, Miers. Bentley and Trimmen, *Med. Plants*, 11.

Nat. Ord.—Menispermaceæ.

Origin.—*Pareira brava* was formerly referred to *Cissampelos Pareira*, Linné, s. *Ciss. microcarpa*, De Candolle (Bentley and Trimmen, *Med. Plants*, 15), which is a woody climber indigenous to the West Indies and Central America, and probably to other tropical countries. It is medicinally employed there, but is not exported. The root as well as the stem rarely reaches an inch (25 Mm.) in diameter, and is often not thicker than a goose-quill; both show no concentric rings in transverse section, the wood consisting of about twenty porous wedges, separated by narrower medullary rays and covered by a gray-brown suberous bark.

The true origin of *pareira brava* was established by Hanbury (1873), and is the species mentioned above, which, according to Peckolt, is known in Brazil as *abutua*. This is a tall woody climber of Brazil and Peru, having large cordate or ovate-cordate, somewhat five-nerved leaves, very small unisexual flowers and purplish-black ovoid one-seeded drupaceous fruits, which form thick bunches resembling grapes in appearance.

Description.—*Pareira brava* comes to us in pieces 3 to 6 inches (7–15 Cm.) long, or even longer, and from about 1 to 4 inches (2–10 Cm.) in diameter, more or less tor-

tuous, dark-brown or blackish-gray externally, and marked with transverse ridges and fissures and with irregular longitudinal furrows. Internally it is of a pale-brown color, when cut exhibits a somewhat waxy lustre, and on breaking shows a fibrous fracture. On transverse section are seen, under a thin bark, two or more concentric zones separated by wavy circles of a waxy tissue of parenchyma, resembling that of the medullary rays; in each zone are found a varying number of harder porous wood-wedges. Each one of the different zones is mostly nearly uniform in width, so that the axis is nearly in the centre of the root. *Pareira brava* is nearly inodorous and has a bitter taste.

Admixtures and Substitutions.—The *stem* of *chondodendron* is sometimes found mixed with the commercial root, which it closely resembles. It is distinguished by being rather more woody, but more particularly by the distinct central pith.

Several drugs derived from menispermaceous plants have been sold in place of *pareira brava*; these consisted of roots, or more frequently of sections of the stem. The

one which was most commonly met with some years ago consisted of woody, more or less flattened pieces, with a thin brown-gray bark, often covered with patches of lichens, and upon transverse section showed numerous woody zones in more or less eccentric layers, so that the axis was removed to one side. This variety of *false pareira brava* is not readily cut with the knife, does not present a waxy appearance of the internal tissue, and, though possessed of a bitter taste, is much less so than the root of *chondodendron*. A second variety of *false pareira* was usually in thinner pieces, of a brown color, very woody and nearly concentrically arranged in the interior, and almost tasteless.

A *yellow pareira brava* has also been met with in commerce, and was imported from Brazil. It consists of the flat, often twisted stems, which Bentley and Trimen presume to be obtained from *Abuta amara*, Aublet. This kind is easily recognized by the eccentric arrangement of its woody zones and by its bright-yellow color internally. C. Morrison (1878) isolated from it an alkaloid which closely resembles berberine, but appears to be distinct from it, since with iodine it gave a reddish-brown crystalline precipitate instead of green spangles.

Hanbury mentions also a *white pareira brava*, derived from *Abuta rufescens*, Aublet, which has numerous concentric layers traversed by very distinct dark medullary rays, the interradial spaces being white and rich in starch. It is known in Brazil as *butua* (Martius, Peckolt), and is not an article of commerce.

Constituents.—Wiggers (1838) obtained an alkaloid from *pareira brava* which was named *pelosine* or *cissampeline*, and was found by Flückiger to be identical with beberine, paricine, and buxine (see pp. 302 and 1014), and to exist also in the stem and root of *Cissampelos Pareira*, Linné, to the extent of about $\frac{1}{2}$ per cent. *Pareira brava* contains it in the same proportion. The pure alkaloid is amorphous, nearly insoluble in water, somewhat soluble in ether and carbon disulphide, but freely soluble in chloroform and acetone, also in alcohol and benzol; its nitrate is sparingly soluble, and its acetate is precipitated by sodium phosphate, by the group reagents for alkaloids, and by iodide, ferrocyanide,

FIG. 205.

Pareira brava: portion of a root, and transverse sections of the same.

ferricyanide, and chromate of potassium; the precipitate with phosphomolybdic acid dissolves in ammonia with a blue color. Feneulle (1821) examined a pareira brava, and obtained a yellow bitter principle soluble in alcohol and ether, a soft resin soluble in alcohol, and brown extractive soluble in alcohol and water.

Off. Prep.—Decoctum pareiræ, Extract. pareiræ, Br.; Extract. pareiræ fluidum (liquidum), U. S., Br.

INFUSUM PAREIRÆ, U. S. 1870.—Infusion of pareira brava, E.; Tisane de pareira, Fr.; Pareira-Infusion, G.—Pareira brava, bruised, a troyounce; boiling water a pint; macerate for 2 hours in a covered vessel and strain.

Medical Action and Uses.—Pareira appears to be analogous in its virtues to uva ursi and chimaphila, since they are chiefly manifested in diseases of the mucous membrane of the urinary organs, and especially in those attended with muco-purulent deposits in the urine. In chronic *pyelitis* and *cystitis* it may be advantageously administered in the form of infusion, decoction, or the official fluid extract. The solid extract is less efficient. The former official infusion was made with an ounce of pareira to a pint of boiling water. The *dose* is represented by 30, and from that to 60, grains (Gm. 2–4) of the root.

PARIETARIA.—PARIETARIA.

Pellitory, Wall pellitory, E.; Pariétaire, Perce-muraille, Fr.; Glaskraut, G.

Nat. Ord.—Urticacæ, Urticææ.

Description.—The following perennial European species has been used:

Par. officinalis, Linné. The stem is diffusely branched, reddish, rough-hairy; the leaves are petiolate, alternate, about an inch (25 Mm.) long, short-hairy, elliptic, entire, and acute: the polygamous flowers are in cymose axillary clusters with an involucre of short bracts, which are united at the base. The plant is perennial, and grows on walls and along roadsides. A variety with a nearly simple stem is *Par. erecta, Koch.*

Par. pennsylvanica, Muhlenberg, indigenous to the United States, probably possesses similar properties. It is an annual, has thin oblong-lanceolate, rather obtuse and opaquely-dotted leaves, and an involucre which is longer than the flowers. It grows on shaded rocky banks.

These plants are inodorous, and have a mucilaginous, saline, and slightly bitter taste.

Constituents.—No complete analysis of these plants has been made. Among the saline constituents of the European species nitrate of potassium is named.

Pharmaceutical Uses.—The *infusion* and *syrup* of *parietaria* are used in France. *Tisane de pariétaire* is made from 1 part of the leaves and 100 parts of boiling water. *Sirop de pariétaire* is prepared by dissolving 19 parts of sugar in 10 parts of the expressed and clarified juice of the herb.

Medical Action and Uses.—Anciently, common wall pellitory was held to be astringent, cleansing, and cooling, and hence was applied in the first stage of *abscesses* and other local inflammations, including *burns*, erysipelas, inflamed hæmorrhoids, gouty joints, and scaly eruptions. Its expressed juice was used as a *gargle*, and in modern times was taken internally, in the dose of 1 or 2 fluidounces (Gm. 32–64), as a diuretic and lithontriptic.

PARTHENIUM.—FEVERFEW.

Herba matricariæ.—Featherfew, E.; Matricaire, Fr.; Mutterkraut, G.

The flowering herb of *Pyrethrum* (*Matricaria, Linné, Chrysanthemum, Persoon, Tanacetum, C. H. Schultz*) *Parthenium, Smith.*

Nat. Ord.—Compositæ, Senecionidææ.

Origin.—Feverfew is a perennial herb growing in waste places in Europe and cultivated in gardens, where it is often seen with double flowers.

Description.—The stem is about 2 feet (60 Cm.) high, furrowed, and has alternate, petiolate, ovate, twice pinnately-cleft leaves about 3 inches (75 Mm.) long, and with obovate or oblong mostly toothed lobes, the teeth terminating with a white point. The flower-heads are in small cymes at the end of the branches, have an involucre composed of linear scales in two rows, a naked hemispherical receptacle, white ligulate obovate and three-toothed ray-florets, and tubular yellow disk-florets. The herb has a peculiar odor resembling that of chamomile, but less agreeable, and a bitter, somewhat acrid taste.

Constituents.—The bitter principle of feverfew has not been isolated; the tannin

is of that variety which produces dark-green precipitates with iron salts. The volatile oil contains, according to Dessaignes and Chatard (1848), a stearopten which has the composition of camphor, $C_{10}H_{16}O$, fuses at $170^{\circ} C.$ ($338^{\circ} F.$), and turns polarized light to the left; also another oxygenated but liquid portion, and probably a hydrocarbon.

Allied Plants.—*PARTHENIUM INTEGRIFOLIUM*, *Linné*, is a North American perennial growing in dry soil in the Southern and Western States. It is about 2 feet (60 Cm.) high, and has oblong or ovate leaves, of which the lower ones are sometimes lobed, and the upper ones merely crenately toothed, and small corymbose flower-heads, with a conical chaffy receptacle, five inconspicuous white pistillate ray-florets, and sterile disk-florets. It has a bitter taste.

PARTH. HYSTEROPHORUS, *Linné*, indigenous to the West Indies, Florida, and Louisiana, resembles the preceding, but has bipinnatifid leaves and numerous small flower-heads. It is employed like feverfew.

SILPHIUM LACINIATUM, *Linné*, is indigenous to the Western and South-western United States, and attains a height of 5 to 10 feet (1.5–3 M.). The root is 2 or 3 feet (60–90 Cm.) long, and contains a circle of resin-ducts in the bark and one near the centre. The flowers are 2 or 3 inches (50 to 75 Mm.) broad, have a cup-shaped involucre composed of imbricated ovate pointed and squarrous scales, and contain numerous yellow tubular sterile disk-florets and many pistillate yellow ray-florets, with compressed, broadly winged, and notched akenes. On the open prairies the lower leaves point north and south, hence the names *compass-plant* and *polar-plant*. The leaves are about 2 feet (60 Cm.) long, the stem-leaves smaller; they are rough and bristly, ovate in outline, pinnately divided, the segments lanceolate, toothed or lobed. All parts of the plant are rich in resin, hence the name *rosin-weed*. The exudation of the stem and leaves forms translucent or transparent tears resembling mastic in appearance, having an agreeable terebinthinate odor and taste, and readily becoming plastic when masticated. It is only partly soluble in the different simple solvents, and, according to L. I. Morris (1881), contains nearly 20 per cent. of volatile oil consisting of a hydrocarbon, and 37 per cent of acid resin, which, on being fused with potassa, does not yield protocatechuic acid; the other constituents are wax, a little sugar, $\frac{1}{2}$ per cent. of inorganic salts, and a whitish tasteless powder insoluble in alcohol, but soluble in chloroform and carbon disulphide.

SILPHIUM TEREBINTHINACEUM, *Linné*, Prairie burdock. It has a smooth stem and smaller flower-heads than the preceding, with smooth and obtuse involucreal scales. The leaves are thick, rough, cordately ovate, and toothed or pinnatifid. The plant likewise yields a resinous exudation.

Medical Action and Uses.—The medicinal properties of *Matricaria parthenium* may be referred to the bitter principle associated with the essential oil which it contains. It has been much used in the treatment of flatulent or atonic *dyspepsia*, in *amenorrhœa*, *dysmenorrhœa*, and simple *intermittent fever*, as well as in conditions of *nervous debility* with hysterical symptoms.

The expressed juice has been administered, and also a decoction and an infusion of the herb. The last is sometimes applied, like chamomile, in fomentations, to allay the pain of local inflammations (*toothache*, *abscesses*, *rheumatism*) and to promote suppuration.

The flowering-tops of *Parthenium integrifolium* are extremely bitter. Many years ago an infusion made from them was reported to be remarkably efficacious in curing *intermittent fever*. 2 ounces (Gm. 64) of the dried flowering-tops in an infusion were thought to be equal to 20 grains (Gm. 1.33) of sulphate of quinine. As no further testimony has been published in confirmation of this statement, it may fairly be assumed to have been exaggerated, and that the alleged cures were only such as occasionally follow the use of various vegetable bitters. The species of *Silphium* above mentioned are more allied by their medicinal virtues to the gum-resins than to the aromatic bitters. They are noticed under *OPOPANAX*.

PASSIFLORA.—PASSION-FLOWER.

Grandille, Fr.; *Passionsblume*, G.

Nat. Ord.—Passifloraceæ.

Origin and Description.—This genus is chiefly confined to tropical America, and consists of climbing shrubs or herbs with alternate undivided or palmately lobed stipulate leaves and perfect flowers. The calyx has five sepals, united below to a short cup-shaped tube, which is fringed in the throat with two or three rows of filaments. The five petals are inserted on the throat of the calyx; the five stamens are united with their filaments, forming a tube from which the long-stalked ovary projects, bearing three somewhat club-shaped styles; the fruit is often edible, berry-like, one-celled, and contains numerous seeds, which are invested with a pulpy covering.

P. LUTEA, *Linné*. It is indigenous to the United States as far north as Southern Penn-

sylvania and Illinois; has obtusely three-lobed leaves with the lobes entire, and greenish-yellow flowers.

P. INCARNATA, *Linné*. It is found as far north as Virginia and Kentucky; has three-lobed serrated leaves, and large whitish flowers with a flesh-colored crown. The berry is orange-yellow, oval, of the size of a hen's egg, and is known as *May-pops*.

P. CÆRULEA, *Linné*. The leaves are five-lobed, the lobes entire; the flowers are greenish, and the fringes blue above; the oval berry is orange-colored.

P. LYRÆFOLIA, *Tussac*. The ovate leaves are divided at the end into three unequal lobes; the flowers are large and red; the berries are globular, and of the size of a cherry.

P. RUBRA, *Linné*. The leaves are two-lobed, the flowers whitish and pale-red, and the berries nearly globular and scarlet-red.

P. MALIFORMIS, *Linné*. The leaves are ovate, pointed, somewhat heart-shaped, entire. The large flowers are white with blue fringes. The fruit resembles an apple in size, shape, and color.

P. QUADRANGULARIS, *Linné*. The branches are quadrangular and winged; the leaves are ovate-cordate, pointed, and entire; the flowers are whitish, and rose-red with a mottled crown; the berry is yellowish, of the size and shape of a goose-egg.

P. FETIDA, *Cavanilles*, with three-lobed leaves, and whitish flowers having a purple crown, is characterized by its strong disagreeable odor.

The fruits of the allied *Paropsis edulis*, *Petit-Thouars*, *Tacsonia tripartita*, *Jussieu*, *T. molissima*, *Kunth*, *T. speciosa*, *Kunth*, and others, are edible.

The constituents of these plants are unknown.

Medical Action and Uses.—Several species of *Passiflora* are endowed with active qualities. *P. quadrangularis*, a West Indian plant, was long ago (1824) stated to cause in animals spasms, paralysis, and a cataleptic condition, and its root was said to be emetic. In Jamaica, *P. rubra* was regarded as narcotic; *P. fetida*, as "pectoral, anti-spasmodic, and emmenagogue;" *P. laurifolia*, as anthelmintic; and *P. lyræfolia*, as diuretic. According to Phares, *P. lutea* and *incarnata*, the passion-flower indigenous to our Southern States, was used by him "with extraordinary success in all cases of *tetanus neonatorum*," in "all sorts of *neuralgic* affections," and in the form of an extract of the root as "an application to *chancres*, *irritable piles*, *erysipelas*, and recent *burns*." An extract prepared by evaporating to dryness the expressed juice of the leaves gathered in May was given in the form of powder, and in the dose of from 1 to 4 teaspoonfuls. For external use an inspissated decoction of the whole plant was used.

PEPO, U. S.—PUMPKIN-SEED.

Semen Peponis.—*Semences de potirons*, Fr.; *Kürbissamen*, G.

The seed of *Cucurbita Pepo*, *Linné*.

Nat. Ord.—Cucurbitaceæ.

Origin.—The plant is probably indigenous to tropical Asia and America, and is often cultivated. It has a rough hollow stem, large five-lobed, serrate leaves, five-branched tendrils, yellow bell-shaped monoecious flowers, and usually large globular or oblong fruits.

Description.—The seeds are $\frac{3}{4}$ to 1 inch (19–25 Mm.) long, flat, broadly ovate, somewhat oblique at the pointed end, white or pale-yellowish, nearly smooth or finely granular on the surface, near the edge and parallel with it marked with a shallow groove, and frequently covered with fragments of a white membranous tissue. The embryo consists of two flat cotyledons of the shape of the seed, and of a short conical radicle. It is inodorous, and has a bland oily taste.

FIG. 206.

Pumpkin-seed: entire, and longitudinally divided.

The seeds of *Cuc. melopepo*, *Linné*, the *squash*, are very similar, rather more obtuse, and less plainly margined. (See also p. 523.)

Constituents.—Dorner and Wolkowich (1870) obtained from pumpkin-seeds 44.5 per cent. of slowly-drying fixed oil, 32.75 starch, and traces of volatile oil, resin, and sugar. They also announced the discovery of an alkaloid, *cucurbitine*; this, however, could not be found by Kopylow (1876), who was also unable to establish the presence of a glucoside. He proved the seeds to contain free fatty acids, and the bland oil to consist of the glycerides of palmitic, myristic, and oleic acids. Heckel (1875) attributes the tæniifuge properties to a resin contained in the tegmen (perisperm?) of the

seed, but Vigier (1876) found the embryo to possess the activity. Dr. L. Wolff (1882) extracted the fixed oil by petroleum benzin, and treated the seeds afterward with alcohol, ether, or chloroform, obtaining a greenish-brown soft resin of an acrid bitter taste. Cadenberg (1881) obtained from the seed of *Cucurbita maxima*, *Duchesne*, by pressure, 20 to 25 per cent. of bland yellow fixed oil, an aromatic principle, emulsin, gum, sugar, and an acid soluble in alcohol and water. When triturated with water the seeds yield a white and bland emulsion; the emulsifying principle is probably a protein compound.

Pharmaceutical Preparation.—*EXTRACTUM PEONIS FLUIDUM.*—Fluid extract of pumpkin-seed, *E.*—It was recommended by Dr. L. Wolff (1882) to be prepared with alcohol, like other fluid extracts.

Medical Uses.—Pumpkin-seeds are among the most efficient remedies for *tapeworm*. Originally referred to as a vermifuge in the last century, it is only within a comparatively few years that their efficiency has been established by numerous and trustworthy witnesses, notwithstanding their neglect by most writers on helminthology. It was stated in 1878 that the people in Northern Italy are in the habit of using them to expel *tæniæ* (Bröking). The remedy has the advantage of being free from any unpleasant taste or harsh mode of action. According to Heckel, the *tæniifuge* virtues reside in the perisperm. According to Béranger-Féraud, who made comparative trials of numerous vermifuges, pumpkin-seed is one of the least reliable for expelling unarmed *tæniæ* (*Bull. de thérap.*, xix, 57: ciii, 104). The fixed oil of the seeds, extracted by ether, has also been used successfully for the same purpose in the dose of $\frac{1}{2}$ ounce (Gm. 16) repeated in two hours, and followed in two hours more by a dose of castor oil. For administration, from 2 to 4 ounces (Gm. 64–128) of fresh pumpkin-seeds should be beaten into a paste with finely-powdered sugar and diluted with water or milk. The night before using the emulsion, and early the following morning also, it has been recommended to administer a large saline purgative for the purpose of washing away the mucus and other intestinal contents that protect the *tænia*. The emulsion, to the amount of a pint, should be taken in three doses at intervals of about two hours, beginning at ten o'clock, the patient remaining very still in bed to prevent vomiting (*Squibb, Ephemeris*, i, 172). Three or four hours later 1 or 2 tablespoonfuls of castor oil should be administered. Before taking the medicine the patient should fast for 24 hours. A fluid extract has also been used. The same treatment has been recommended for *lumbricoid* worms. *

PEPSINUM SACCHARATUM, U. S.—SACCHARATED PEPSIN.

Pepsinum, P. G.; *Pepsin*, Br.; *Pepsina*, F. Cod.—*Pepsine*, Fr.; *Pepsin*, G.

Pepsin, the digestive principle of the gastric juice, obtained from the mucous membrane of the stomach of the hog, and mixed with powdered sugar of milk.—*U. S.* A preparation of the mucous lining of a fresh and healthy stomach of the pig, sheep, or calf.—*Br.*

Preparation.—The stomach of one of these animals recently killed having been cut open and laid on a board with the inner surface upward, any adhering portions of food, dirt, or other impurity are to be removed and the exposed surface slightly washed with cold water; the cleansed mucous membrane is then to be scraped with a blunt knife or other suitable instrument, and the viscid pulp thus obtained is to be immediately spread over the surface of glass or glazed earthenware and quickly dried at a temperature not exceeding 100° F. The dried residue is to be reduced to powder and preserved in a stoppered bottle.—*Br.*

This product, it will be observed, consists merely of the carefully-dried mucous membrane of the stomach. The U. S. and German Pharmacopœias do not give a process for the preparation of pepsin, but from the descriptions it is evident that a product is intended as obtained by the process of Prof. E. Scheffer, published in 1872, and which is as follows: The mucous membrane of the well-cleaned, fresh stomach of the hog is dissected off, chopped finely, and macerated in water acidulated with hydrochloric acid. After several days the liquid is strained, clarified by rest and decantation, and mixed with an equal bulk of a saturated solution of sodium chloride. The pepsin is separated floating upon the surface, drained upon muslin, and strongly pressed to remove the solution of salt. If permitted to dry, it becomes very tough, parchment-like, or leathery. Obtained in this way, it still contains mucus, phosphate of calcium, and table-salt, from the two former of which it is freed by resolution in water, filtering, again precipitating by sodium chloride, and expressing; the table-salt which now remains with it is best removed by allowing the pressed pepsin to dry, when the salt will effloresce upon the

surface and will dissolve on short immersion in water. It then constitutes Scheffer's *purified pepsin*, which dissolves in acidulated water to a clear and colorless solution.

To obtain *saccharated pepsin*, the expressed residue, while still damp, is thoroughly mixed with milk-sugar, and when the mixture has become air-dry its digestive power is ascertained, and the remainder is then diluted by the addition of milk-sugar, so that it will digest the proportion of coagulated albumen indicated below (see *Tests*).

Various other processes for obtaining pepsin have been recommended. Kuchne triturated the mucous membrane of the stomach with clean sand and filtered the liquid, which, after being dried in thin layers at a temperature of 40° C. (104° F.), was obtained by J. Lamatsch in the form of a brownish-yellow somewhat hygroscopic powder. The French Codex directs pepsin to be prepared from the stomach of the sheep: the mucous membrane is macerated for 2 hours in water at 15° C. (59° F.), the strained liquid precipitated with lead acetate, the precipitate washed, then diffused in water, and decomposed by hydrosulphuric acid; the liquid is rapidly filtered, and evaporated below 45° C. (113° F.) in very shallow vessels. Thus prepared, it forms a brownish-yellow firm mass. Instead of evaporating the solution, Hottot recommended the precipitation of the pepsin by sodium sulphate, and its drying so as to form pale-brown scales.

Selldén (1873) observed that the mucous membrane is not deprived of pepsin by maceration in acidulated water, but that by digestion at 37° C. (98.6° F.) about double the amount of pepsin is obtained: the mother-liquor from the precipitated pepsin, after having been deprived of salt by dialysis, possesses only very slight digestive properties. That pepsin exists partly in the stomach in an insoluble form has also been demonstrated by Béchamp and by Gautier (1882); the insoluble granules, termed *microzymes*, gradually dissolve in water on digestion.

Properties.—The British Pharmacopœia describes pepsin as being a light yellowish-brown powder, having a faint but not disagreeable odor, and a slightly saline taste, without any indication of putrescence. It is soluble to a very small degree in water or spirit.

Saccharated pepsin is a white or pale-yellowish powder, which is not hygroscopic, has but a slight odor, a sweetish taste, and a slight acid reaction. It is not completely soluble in water, floccules of *syntonin* remaining behind, which, however, are dissolved by diluted hydrochloric acid. The solution, slightly acidulated with hydrochloric acid, furnishes precipitates on the addition of alcohol, tannin, and sodium carbonate or bicarbonate, an excess of the last two precipitants yielding again a clear solution. Except in minute quantities, chloride of sodium impairs the digestive power of pepsin; the same is true of alcohol. When a solution of pepsin is rendered alkaline, and afterward again acidulated, it has lost its power of dissolving fresh coagulated albumen. An aqueous solution of pepsin will decompose in a short time: after the addition of sufficient hydrochloric acid it remains clear, but gradually loses its effects on albumen. Glycerin, on the other hand, preserves its virtues. (See LIQUOR PEPSINI.) Pepsin, particularly after it has been slightly acidulated, coagulates milk: 80,000 parts of the latter were found by Scheffer to be curdled by 1 part of purified pepsin.

Tests.—The solution of pepsin in water acidulated with hydrochloric acid should be clear or only slightly opalescent, showing the absence of an undue proportion of mucus, which would gradually impart a disagreeable, finally an ammoniacal, odor. 1 part of pepsin dissolved in 500 (218 *Br.*, 1500 *P. G.*) parts of water, acidulated with 7.5 (2.5 *Br.*, *P. G.*) parts of hydrochloric acid, and mixed with 50 (100 *P. G.*) parts of hard-boiled egg-albumen in thin shavings, form a mixture which on being kept at a temperature of 38° to 40° C. (100° to 104° F.) should become a slightly opalescent solution (in 30 minutes at 54.4° C. = 130° F., *Br.*) in 5 or 6 hours.—*U. S.*

Composition.—Absolutely pure pepsin is unknown: it probably contains the same elements present in other protein compounds. Syntonin has a similar composition, but is insoluble in water and neutral saline solutions; its presence in pepsin made by Scheffer's process was shown by Selldén (1873).

Allied Substances and Products.—**GASTRIC JUICE.** As taken from the stomach and filtered from the undigested food, this forms a clear, transparent, limpid liquid of a pale-yellow or brownish color, of a slight peculiar odor, and of a somewhat saline and acidulous taste. It is but slightly heavier than water, and has a strongly acid reaction, which has been attributed to free lactic and hydrochloric acids, to acid phosphates, and to acid hippurates. The gastric juice retains its digestive power for a long time, even after it has become mouldy. Lehmann obtained from it between 0.1 and 0.132 per cent. of free hydrochloric, and between 0.32 and 0.585 per cent. of lactic acid. The latter was observed by Richet (1878) to be identical with *sarcocollactic acid* of

horseflesh. The total percentage of all solids contained in gastric juice is between 1 and 1.5 per cent., but varies in different animals, and is invariably increased by admixture with saliva. The chlorides amount to nearly $\frac{1}{2}$ per cent., among them small quantities of ammonium and calcium chlorides. Phosphates of calcium, magnesium, and iron amount to $\frac{1}{2}$ or $\frac{1}{4}$ per cent., but alkali sulphates and phosphates cannot ordinarily be detected.

PAPAIN, PAPAYOTIN, is obtained from the milk-juice of the *melon tree* or *papaw*, *Carica Papaya*, *Linneé*, s. *Papaya vulgaris*, *De Candolle*: nat. ord. *Papayaceæ*. The tree is indigenous to tropical America, but now is cultivated and wild in most tropical countries. The trunk is mostly undivided, 20 to 25 feet (6 to 7.5 M.) high, has a crown of long-petioled, large, palmately-lobed leaves, and bears as fruit fleshy berries which under cultivation attain a length of 12 inches (30 Cm.) and a thickness of 6 inches (15 Cm.). Peckolt (1879) found the fruit to contain albuminoids, resin, sugar, fat, tartrates, citrates, malates, etc.; the milk-juice of the unripe fruit, dissolved in water, yields with alcohol *papayotin* as a snow-white, inodorous, and nearly tasteless powder, which is very soluble in water and glycerin, but insoluble in other solvents. Wurtz and Bouchut (1879) named it *papaïn*. Wittmack (1878) showed that the filtered milk-juice is not coagulated by heat. The residue from dialysis, precipitated by alcohol, gave to Wurtz (1880) a product containing only 1 to 3 per cent. of ash, and having a composition closely resembling that of albuminoids. The aqueous solution foams when agitated, and is not precipitated by acetic or orthophosphoric acid, but nitric or hydrochloric acid yields a precipitate soluble in excess of acid. Precipitates are also obtained with tannin, picric acid, platinic chloride, corrosive sublimate (on boiling), copper sulphate (violet), and Millon's reagent (yellowish-white, on heating brick-red).

Bouchut (1880) found the milk-juice of the *fig tree* to contain a similar digestive ferment.

PEPTONE. This is the product of the digestion of albuminoid substances. Peptones are readily soluble in water, and this solution is not disturbed by boiling nor by the addition of acids or alkalies. Neutral solutions of peptone are precipitated by alcohol, tannin, and by various salts. Acid solutions yield precipitates with potassio-mercuric iodide, bromine-water, and other group reagents for alkaloids, but these precipitates are soluble in excess of peptone (Tanret, 1881). Brieger (1883) extracted from some peptones by boiling alcohol an amorphous poisonous alkaloid resembling the ptomaines in behavior. Peptone is colored yellow by nitric acid, and gives with Millon's reagent, on warming, a red precipitate, and with Fehling's solution violet-red color.

Peptone is readily assimilated by the intestinal mucous membrane. Pöchl (1882) states that peptones may be again converted into albuminoids by the influence of alcohol, various alkali salts, and other agents having much affinity for water. *Peptonized meat* has been recommended as a nutritive medicine. The liquid resulting from the artificial digestion of lean meat is strained, neutralized with sodium bicarbonate, and the filtrate evaporated until it has the density 1.208, when it is stated to contain 50 per cent. of peptone (Petit, 1881), and may be preserved by the addition of glycerin and combined with ferric chloride, mercuric chloride, and other salts. By desiccating its concentrated solution upon oiled plates peptone may be obtained in scales resembling gelatin, which are hygroscopic, but not deliquescent on exposure.

Pharmaceutical Preparations.—VINUM PEPSINI, s. Vinum pepticum, s. Essentia pepsini, *P. G.*; Wine of pepsin.—Macerate for 6 days 50 parts of pepsin with 50 parts each of glycerin and distilled water, 1845 parts of good white wine, and 5 parts of hydrochloric acid, and filter. The liquid is of a clear yellowish color and has a vinous odor and slightly acid taste.

LIQUOR SERIPARUS.—Rennet wine, Liquid rennet, *E.*; Laabessenz, *G.*—3 parts of the mucous membrane of calves' rennet are macerated for 3 days with 26 parts of sherry wine and 1 part of chloride of sodium. After filtration liquid rennet is a clear yellowish liquid.

Off. Prep.—Liquor pepsini, *U. S.*

Medical Action and Uses.—According to Albertoni, the injection into a dog's veins of an aqueous faintly acid solution of pepsin in water (1 in 1000) renders the coagulation of the blood very slow and imperfect and diminishes the amount of fibrin produced. He inclined to regard pepsin as normally exercising "a by no means unimportant function in connection with the processes of tissue-change." These results, if real, relate to quite a different operation from that which has heretofore been attributed to pepsin, and which entirely concerns its action upon the food during gastric digestion.

On the admission of pepsin into medical practice it soon acquired a brilliant reputation as a remedy for numberless dyspeptic ailments indirectly engendered by the wear and tear of civilized life, as well as for those directly produced by certain affections of the structural elements of the stomach itself. The introduction into this organ from without of a substance necessary to the solution of the food, but which it was incompetent to furnish by its own power, was a happy thought of the rational therapist, and which has been repeated less rationally in the case of pancreatin. The practical results of its application were apparently, and at first, as flattering as possible; but confidence in the remedy began to decline when it became certain that nearly all of the numerous preparations of pepsin were absolutely inert intrinsically, or had become so from the changes induced by time or

by the various substances associated with the pepsin they originally contained. It is unnecessary to describe in detail the various *dyspeptic disorders* which might be profitably treated by a really active preparation of pepsin; it will suffice to say that, besides those already referred to, there is the common gastric derangement of infants and of children during the period of dentition, induced usually by the pain and irritation of this process, which being duly corrected, the patients are enabled to bear with comparatively slight disorder of function the continued action of the disturbing cause. Other causes beside teething may occasion the same condition, such as unwholesome air and food. Under the use of pepsin sometimes the vomiting and diarrhœa cease, the abdominal distension subsides, and the increased flesh and improved complexion testify to the more complete assimilation of the food. In numerous cases occurring during convalescence from exhausting acute diseases and in the course of chronic affections, more or less of the same effect may be hoped for from the administration of pepsin in a really active condition. Still, we believe that general clinical experience will support the deduction of Dana from his experiments, "that good pepsin has a *real* though not a *great* medicinal value" (*Amer. Jour. of Med. Sci.*, Oct. 1882, p. 347). It seems probable that pepsin prepares albuminous compounds for absorption, for Catillon fed a dog by the rectum with eggs prepared with pepsin, and the animal retained its weight and temperature during the two months that the experiment continued. As soon as the pepsin was omitted it began to lose flesh and heat (*Bull. de thérap.*, c. 233). It is unnecessary to do more than mention that pepsin has been applied locally to dissolve diphtheritic membrane, and also coagulated blood retained in the urinary bladder.

Perfectly fresh pepsin may be prescribed in *doses* of about 10 grains (Gm. 0.60) immediately before or after each meal. It should be mixed with arrowroot and given in a little sweetened water. Liebreich has found that to preserve the ferment of pepsin in the liquid state glycerin is the only reliable agent.

The ripe fruit of *Carica papaya* is eaten when fresh, and is also preserved as food; the unripe fruit is pickled. A syrup is made of the expressed juice, which is also used as "a sedative and expectorant." The fresh milky juice is a drastic cathartic, and is employed as a vermifuge, as are also the seeds. Cases of severe, and even fatal, poisoning, with symptoms of gastro-enteritis, have arisen from the use of this juice (*Bull. de thérap.*, xcviii. 279). It has been alleged that the sap of the tree acts as a caustic on the gastrointestinal mucous membrane of animals, even perforating the walls of the digestive canal (*Bull. et Mém. Soc. thérap.*, 1880, p. 78). Diluted, it has been used as a cosmetic to remove freckles and other cutaneous affections. The bruised seeds are applied as poultices (*Amer. Jour. Phar.*, l. 559).

It is said that finely-chopped meat macerated in a 10 per cent. watery solution of the juice for 24 hours becomes completely dissolved, and exhales a strong and ammoniacal smell. The solution is quickened by heat (*Med. Record*, xvii. 147). Except in regard to the putrefactive smell this statement has been confirmed (*Bull. de thérap.*, xcviii. 279); and it is added that the "digestion" of the meat is more perfect than that caused by ordinary pepsin. Wurtz compares papayotin to a solution of pancreatin (*Ibid.*, xcix. 32, 464), and others have found it superior both to pepsin and to pancreatin in the power of digesting either cooked meat or hard-boiled white of egg. It is added that the fruit of the papaw tree has long been used in the West Indies to render beefsteaks tender (*Practitioner*, xxv. 301).

Rosbach claims that papayotin is a good solvent for the exudation in diphtheria and croup. He used a 12 per cent. watery solution, and applied it with a soft brush (*Practitioner*, xxvii. 289). Koths and Ascher, on the other hand, refuse to this agent any specific action in the case, and state that while the hourly application of a 5 per cent. solution is efficient in dissolving overlying membranes, it exerts no action upon diphtherial "infiltration" (*Centralblatt f. Therapie*, i. 250).

INGLUVIN is obtained from the gizzard of the domestic fowl, and is supposed to promote digestion in the same manner as pepsin. But Dr. Edes and Dr. Ellis both failed to discover that it displayed any such action upon albumen as pepsin exerts (*Boston Med. and Surg. Jour.*, April, 1883, p. 381). It has long been a popular domestic medicine. In 1877 the attention of physicians was called to it by Dr. Shelley (*Phila. Med. and Surg. Reporter*, June, 1877) as a remedy for *nausea* and *dyspepsia* associated with debility (Kennedy, *Phila. Med. Times*, x. 104). In doses of 15 grains before meals it has suspended the vomiting of pregnancy (*Med. Record*, xii. 664; *Practitioner*, xxvi. 43). Dr. Dobbs advises that it be given very early in the morning in the dose of 10 grains, at 8 or 9 o'clock 15 grains more, and that an hour later a light breakfast be taken, and that this

administration be continued for several days, while the dose is increased to 20 grains (*Brit. Med. Jour.*, 1881, i. 86). Sawyer recommends that in atonic dyspepsia it be given in doses of 10 grains thrice daily, in powder sprinkled on bread, immediately *after* meals (*Practitioner*, xxvi. 43).

PERSICA.—PEACH.

Pêcher, Fr.; *Pfirsich*, G.

Persica vulgaris, *De Candolle*, *Amygdalus Persica*, *Linné*.

Nat. Ord.—Rosaceæ, Amygdaleæ.

Description.—The peach tree is indigenous to South-western Asia, and is at present extensively cultivated in most temperate countries. It is of medium size, and has a nearly smooth brown bark and spreading branches. The *leaves* are alternate, short-petiole, about 4 inches (10 Cm.) long, lanceolate, pointed, closely serrate, green, and smooth on both sides. The *flowers* appear in April, are axillary, have a bell-shaped and five-cleft calyx, five ovate, reddish petals, about twenty-five stamens, and a single ovary developing into a subglobular drupe, with a hard and furrowed putamen and containing a seed resembling the almond. The leaves, flowers, and seeds when bruised exhale a bitter-almond odor and have a bitter taste.

Constituents.—The young branches, leaves, flowers, and seeds, after maceration in water and distillation, yield a volatile oil which is chemically identical with oil of bitter almond. Geiseler (1840) proved the presence of about 3 per cent. of crystallizable amygdalin in the seeds. The fixed oil of the latter is bland, and resembles expressed oil of almond (see p. 1044).

Physiological Action and Medical Uses.—The bark, the leaves, the kernels, and even the flowers, are endowed with active properties, which they owe in part to hydrocyanic acid. The flowers are chiefly laxative, and the leaves are not destitute of this quality. Indeed, they have been used as a substitute for manna, and especially for their *vermifuge* effect; they have also been reputed to cure *intermittent fevers* and to allay the pain of *nephritic colic*, as well as to promote the discharge of calculi by causing diuresis. Bruised and applied to the abdomen, they are said to relieve colic produced by indigestion. They are also reported to have cured *whooping cough*. They have been applied to arrest slight *hæmorrhages*. Peach-kernels have frequently produced poisonous effects. A child three years old who had eaten a quantity of them became insensible, with slow, deep, sobbing respiration, slight twitching of the mouth, icy-cold extremities, lividity of the fingernails, and dilated pupils. It was restored by an emetic (Keating). In other cases active vomiting and purging, with convulsions, have been observed. The possibility of these effects having resulted from the indigestibility of the kernels should not be overlooked. The leaves, and also the flowers, may be prescribed in an infusion, and a syrup prepared from them or from the bark has also been used.

PETROLATUM, U. S.—PETROLATUM.

Paraffinum molle, Br.; *Unguentum paraffini*, P. G.; *Paraffinum unguinosum*, *Adeps petrolei*.—*Petroleum ointment*, *Soft paraffin*, *Paraffin jelly*, E.; *Paraffinbutter*, G.

A semi-solid substance consisting of hydrocarbons, chiefly of the marsh-gas series ($C_{16}H_{34}$, etc.), obtained by distilling off the lighter and more volatile portions from American petroleum and purifying the residue. Melting-point about 40° C. to 51° C. (104° F. to 125° F.), the first constituting the softer (*Petrolatum molle*), and the second the firmer (*Petrolatum spissum*) variety. When petroleum ointment is prescribed by the physician without specification of the melting-point, the low-melting variety, liquefying at about 40° C. (104° F.), is to be dispensed.—*U. S.*

Preparation.—When in the distillation of crude petroleum by means of superheated steam the heavier hydrocarbons begin to come over, the receiver is changed, and the butyraceous distillate is filtered through a long column of well-dried granular boneblack, the temperature being kept at 45° C. (113° F.) or higher, so as to keep the product in a melted condition while percolating through the charcoal. The first portion of the percolate is colorless or nearly so; the subsequent portions pass more colored. The boneblack retains nearly its own weight of the soft paraffin. The crude paraffin which settles in the storing-tanks of coal oil is first deprived of the adhering lighter hydrocarbons by distillation, and is afterward filtered through boneblack as stated. (See also PARAFFINUM.) In Europe sulphuric acid is used for the purification of paraffins.

Properties.—Petrolatum is "a yellowish or yellow fat-like mass, transparent in thin layers, more or less fluorescent, especially when melted, completely amorphous, tasteless, and odorless, or giving off, at most, only a faint petroleum odor when heated, and having a neutral reaction. When gently heated until the mass is almost entirely melted, the liquid portion has a sp. gr. varying from 0.835 to 0.860. It is insoluble in water, scarcely soluble in alcohol or in cold absolute alcohol, but soluble in 64 parts of boiling absolute alcohol, and readily soluble in ether, chloroform, disulphide of carbon, oil of turpentine, benzin, benzol, and in fixed or volatile oils. When heated on platinum-foil it is completely volatilized without emitting the acrid vapors of burning fat or resin."—*U. S.*

UNGUENTUM PARAFFINI, *P. G.*, Paraffin ointment. Melt together solid paraffin 1 part and liquid paraffin 4 parts. This is somewhat crystalline, and on exposure becomes hard from the slow evaporation of the liquid portion. It is not a suitable substitute for petrolatum. Soft paraffin, *Br.*, melts not below 35° C. (95° F.), and has the sp. gr. .840–.870.

Tests.—"If 5 Gm. of petroleum ointment are digested for half an hour with 5 Gm. of soda and 25 Gm. of water, the aqueous layer separated, and supersaturated with diluted sulphuric acid, no oily substance should separate (absence of fixed oils or fats of vegetable or animal origin, or of resin). Liquefied petroleum ointment agitated with sulphuric acid of sp. gr. 1.540 should not acquire a dark color within 2 hours (absence of readily carbonized organic impurities)."—*U. S.*

Allied Drug.—**ICHTHYOL** is the name of a substance obtained by the distillation of a peculiar bituminous earth. It is of the consistence of petrolatum, of a greenish color, and of an unpleasant cabbage-like odor. It contains 2.5 to 10 per cent. of sulphur, is soluble in spirit of ether, and forms a milk-white mixture with water.

Action and Uses.—This preparation is intended to be used as a substitute for lard in making many ointments, and for oil as a protecting and lubricating substance. It is absolutely unirritating, and has the advantage of not becoming rancid by keeping.

Ichthyol has been used by Unna in the treatment of papular and moist *eczema*. It was incorporated with lard or vaseline in the proportion of from 10 to 50 per cent., the former being applied to the moist and the latter to the dry eruption. The same physician recommends it as a local application in acute and also in chronic articular *rheumatism*, both as a liniment and as the spray of a 10 per cent. spirituous solution. He also found it a useful palliative of various acute and chronic affections of the *air-passages*, when its vapors, given off by gentle heat, were inhaled. For such purposes a tablespoonful in one or two quarts of water was employed. It has been applied with alleged advantage in congestive forms of *pharyngitis* and as a cure for *scabies* (*Edinb. Med. Jour.*, xxviii. 1042; *Centralblatt f. d. g. Therap.*, i. 363).

PETROLEUM.—PETROLEUM.

Oleum petrae.—Rock oil. Coal oil, *E.*; *Pétrole*, *Huile minérale*, *Fr.*; *Steinöl*, *Bergöl*, *G.*

Origin.—Petroleum is met with in several parts of North America, on the west coast of the Caspian Sea, and to a limited extent in most European countries. It oozes from the ground, frequently mixed with water, but is obtained in largest quantities from wells sunk in the ground. Its formation in the soil has been the subject of much speculation. H. Byasson (1876) explains its origin from salt water penetrating into cavities of the terrestrial crust and carrying with it lime salts and other materials; if these reach a depth where the temperature is sufficiently high, and come in contact with metallic substances, such as iron or its sulphurets, hydrocarbons are formed, the properties of which are modified by causes acting after their formation, such as partial distillation, etc.

Properties.—As naturally obtained, petroleum varies in consistence from thin limpidity to the thickness of molasses or tar, and in color from pale-yellow to blackish-brown, usually showing a distinct fluorescence. Its specific gravity is generally between 0.8 and 0.9, but some varieties slightly exceed water in density. The heavier and dark-colored kinds yield, on rectification, light and limpid oils, and leave a residue consisting of *paraffin* and solid *bitumen*, a variety of which is found native as *asphaltum*. The latter is black, glossy, and brittle, while the bituminous residues from coal-oil distillation are less glossy and scarcely brittle at the ordinary temperature. The solid as well as the liquid fractions of petroleum are inflammable and burn with a bright sooty flame; the vapors of the more volatile kinds, mixed with atmospheric air, are highly explosive.

Barbadoes tar and *Seneca oil* are two varieties of petroleum which were formerly

employed; they are viscid and dark-colored, the last named lighter, thinner, and of a less disagreeable odor than the former.

Constituents.—Petroleum consists of a large number of hydrocarbons, belonging to two homologous series—namely, that of *marsh gas*, of the general formula C_nH_{2n+2} (see PARAFFINUM), and of *olefiant gas* (olefin or ethylene series), having the formula C_nH_{2n} . On treating petroleum with strong sulphuric acid the olefins, coloring matter, and some other constituents are removed, and the hydrocarbons of the paraffin series left. The hydrocarbons of both series exist also in isomeric modifications which differ from the normal compounds in volatility and some other properties. Those containing C_4 and less are gases at the ordinary temperatures; the relation of the others is shown by the following table (see also PARAFFINUM):

	Normal.	Iso.		Normal.	Iso.
Pentane, C_5H_{12} , boils at	38° C.	30° C.	Pentene, C_5H_{10} , boils at	37° C.	35° C.
Hexane, C_6H_{14} , “	70° C.	62° C.	Hexene, C_6H_{12} , “	70° C.	65° C.
Heptane, C_7H_{16} , “	98° C.	90° C.	Heptene, C_7H_{14} , “	100° C.	—
Octane, C_8H_{18} , “	124° C.	118° C.	Octene, C_8H_{16} , “	125° C.	—

These compounds are to some extent separated by fractional distillation. The portion boiling below 50° C. (122° F.), being collected by itself, constitutes *naphtha* or *gasolene*, and consists almost exclusively of pentane and pentene; but if the vapors are well refrigerated the product contains also *butane*, C_4H_{10} , boiling at 1° C. (33.8° F.), and constitutes *rhigolene*, which requires to be kept in strong and well-corked bottles and in a cool place, since it evaporates rapidly at the common temperature. The naphtha freed from the low-boiling hydrocarbons is commercially known as *benzin* or *petroleum benzin* (see page 310); its specific gravity is about .67. The portion boiling at a higher temperature is separately collected and furnishes *kerosene*, *photogene*, or *coal oil*, which is largely employed for illuminating purposes; its safety for that use depends upon the absence of the low-boiling hydrocarbons. At a still higher temperature paraffin oils, paraffin jelly, and paraffin wax (see PARAFFINUM) pass over, and the residue left in the still at a temperature of about 300° C. (572° F.) constitutes the ordinary *asphaltum* or *bitumen*. Heptane was ascertained by Thorpe (1879) to be a constituent of the volatile oil of *Pinus Sabiana* (see page 1091).

OLEUM PETRÆ ITALICUM, s. *Petroleum crudum*. Yellowish or reddish, limpid, iridescent, of a peculiar bituminous odor, soluble in fixed and volatile oils, in ether and absolute alcohol, with difficulty soluble in alcohol; specific gravity 0.75 to 0.85. This is sometimes employed in Europe.

Physiological Action.—Taken internally in excessive doses, it has caused oppression, giddiness, palpitation, faintness, and headache, but no tendency to stupor, or even sleep. In one case frightful tonic and clonic convulsions occurred; in another the pulse fell from 82 to 48, the pupils were contracted, the skin hot, the respiration hurried, and the voice weak. It is remarkable that it does not produce vomiting, nor, usually, diarrhœa. In only one case is death said to have resulted from it, with symptoms of gastroenteritis, on the twentieth day after the oil was taken. The urine has a peculiar aromatic odor.

Medical Uses.—Petroleum was used by the Egyptians for embalming dead bodies, as is well known. Dioscorides and Pliny refer to it as being either liquid or solid. The first of these writers speaks of its application in opacity of the cornea; the Arabians refer to its emmenagogue and diuretic qualities, to its use in (humid) asthma and for cough, to its vulnerary and anthelmintic powers, and especially to its being used in suppositories to remove ascarides of the rectum. They speak particularly of its use by friction to relieve rheumatic pains, assuage colic, and expel flatus, and of its efficacy in bringing on uterine contractions and expelling the dead fœtus. In more recent times it was highly esteemed in the cure of *tapeworm* and other verminous affections, and for overcoming *retention of urine* caused by atony of the bladder. It was also credited with singular virtues as an embrocation in *paralysis*, *contraction*, and *stiffness* of the *joints*, *atonic rheumatism* and *tumors*, *chilblains*, etc. Still more recently the popular use of it as a remedy for *itch* has been imitated by physicians, and many cures by its means have been reported. It is said to be one of the promptest of the remedies for this affection, but it is also stated by eminent authorities not only to fail in a majority of cases, but in some to be a painful application, and to produce sleeplessness, intoxication, and eczematous eruptions of the skin. It has been found curative in *prurigo*. Dr. Frayer used petroleum in the treatment of *wounds*, and regarded it as possessing “some, if not all, of the advantages

assigned to carbolic acid for this purpose." The ancient use of this substance for the cure of chronic *bronchitis* has been revived with such advantage as attends the administration of various terebinthinate and balsamic medicines (*Practitioner*, xxiv. 375). The crude oil is greatly to be preferred to the refined, and wherever petroleum is manufactured it is considered a sovereign remedy not only for bronchitis, but for all other mucous profluvia, as well as for internal lesions of every sort (Blache, *Bull. de théor.*, xev. 489; Campardon, *ibid.*, xevii. 463). It has been applied with alleged success to the removal of diphtheritic false membranes (*Bull. et Mém. Soc. thérap.*, Juin, 1882, p. 135; *Phila. Med. News*, xli. 509), and suggested as a remedy for *furcus* (*Boston Med. and Surg. Jour.*, Nov. 1882, p. 453).

Petroleum may be given internally in doses of from 5 to 10 drops (Gm. 0.30–0.60) in the same way as oil of turpentine. For the cure of tapeworm larger doses, such as $\frac{1}{2}$ fluidrachm (Gm. 2), may be used. In liniments its odor may be partially masked by that of some agreeable essential oil. It is sometimes united with cosmoline as an excipient, which renders it easy of application in all the diseases mentioned above. Its operation and advantages are nearly identical with those of paraffin and vaseline. Petroleum may be administered in capsules, but as this method allows the pure oil to irritate the stomach, it is preferably given in an emulsion made with white of egg, sugar, and tragacanth, so as to form a semi-liquid mixture.

RHIGOLENE. Used with an ordinary hand spray-producer, furnished with metal tubes, it readily produces a temperature of 15° below zero F. It is therefore more reliable than ether for this purpose, although, if its application be too long continued, it may cause frost-bite, and even mortification. It was used in a great variety of cases in which local anaesthesia was required to render certain surgical operations painless, but it does not seem to have commended itself to general adoption, on account probably of its explosiveness.

PETROSELINUM.—PARSLEY.

Persil, Fr.; *Petersilie*, G.

The root of *Petroselinum sativum*, *Hoffmann*, s. *Apium Petroselinum*, *Linné*.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—Parsley is indigenous to Southern Europe, and is much cultivated for culinary purposes. It is a biennial 2 or 3 feet (60–90 Cm.) high, and has bi- or tri-pinnate smooth and shining leaves, with ovate wedge-shaped three-cleft toothed or crisp leaflets.

Description.—**RADIX PETROSELINI.** The root is 6 or 8 inches (15–20 Cm.) long, $\frac{1}{2}$ to 1 inch (12–25 Mm.) thick, when dry pale brown-yellow externally, annulate

FIG. 207.

Parsley-root: transverse section, magnified 3 diameters.

above, longitudinally wrinkled below, and marked with transverse corky ridges: it breaks with a short and mealy fracture, upon which is seen a thick white and in the inner layer radially striate bark, a fine dark-colored cambium-line, and a yellow, soft medullium with irregular medullary rays. The bark and medullary rays contain scattered brown resin-cells. The root is faintly aromatic and has a sweetish taste.

FRUCTUS PETROSELINI. The fruit is $\frac{1}{16}$ to $\frac{1}{12}$ inch (1.5–2 Mm.) long, ovate, laterally flattened, greenish-brown, each mericarp with five light brown-gray filiform ribs and six oil-tubes, and has a strong aromatic odor and a warm taste.

Constituents.—The root contains starch, mucilage, sugar, volatile oil, and *apin*, $C_{24}H_{36}O_{13}$. The latter is best obtained from the fresh herb by boiling with water, expressing while hot, and purifying the green gelatinous precipitate which forms on standing by dissolving it in hot water. It was discovered by Braconnot (1843), and is a white, inodorous, and tasteless powder, perhaps a glucoside, soluble in boiling water and alcohol, separating on cooling jelly-like; the hot aqueous solution acquires a blood-red color on the addition of ferrous sulphate.

The fruit was examined by C. Rump (1836), and found to contain 1.4 per cent. of volatile oil and 22 per cent. of fixed oil, besides mucilage and other common principles. *Oil of parsley* is colorless or yellowish, has the specific gravity 1.01 to 1.14, dissolves in 2½ parts of 80 per cent. alcohol, commences to boil near 170° C. (338° F.), and consists of a hydrocarbon, $C_{16}H_{16}$, and a stearopten, $C_{12}H_{14}O_4$. This *parsley camphor* crystallizes in silky needles or prisms which fuse at 30° C. (86° F.) and are partly sublimable; it is

readily soluble in strong alcohol, ether, and fixed and volatile oils, and has a faint odor of parsley and a camphoraceous, pungent taste.

Joret and Homolle (1855) separated from parsley-fruit *apiol*, by exhausting with alcohol, treating the tincture with animal charcoal, distilling off three-fourths of the alcohol, dissolving in ether, evaporating the ethereal solution, macerating the residue with levigated litharge, and filtering through charcoal. A simpler process was recommended by L. Wolff (1877). The fruit is exhausted with petroleum benzin, the solvent evaporated, and the residue treated with strong alcohol, on the evaporation of which *apiol* is left. It is a colorless oil of spec. grav. 1.07, becomes turbid without congealing at -12° C. (10.4° F.), has an acid reaction, the odor of parsley, and a pungent taste, forms a kind of emulsion with alkalies, and is easily soluble in alcohol, ether, chloroform, and in glacial acetic acid.

Allied Plant.—*APIUM GRAVEOLENS*, Linné.—Celery, *El.*; Ache, Céleri, *Fr.*; Sellerie, Eppich, *G.*—A biennial plant indigenous to Europe, where it grows wild in ditches and meadows. It has a spindle-shaped whitish root, which, like the dark-green glossy pinnate or ternate lobed and coarsely serrate leaves, has a disagreeable odor, an acrid bitter taste, and is regarded as poisonous. Under cultivation the root becomes short, thick, tuberous, juicy, and of an agreeable flavor, and with the blanched stalks is much used as a salad. The fruit (*FRUCTUS APII*, *celery-seed*) is about $\frac{2}{3}$ to $\frac{1}{6}$ inch (1–1.5 Mm.) long, roundish-ovate, laterally flattened, brown, with lighter-colored ribs, and smooth; the mericarps are usually separate, somewhat curved, flat on the face, and contain about twelve thin oil-tubes; odor and taste are agreeably aromatic. All parts of the cultivated plant contain volatile oil, sugar, mucilage, and fat; the root and leaves also mannit. The United States imported 73,683 pounds of celery-seed in 1881.

Physiological Action.—In modern as in ancient times parsley has been used as a carminative, discutient, and diuretic. The root is said to be more actively diuretic than the rest of the plant; its fruit resembles in its action those of fennel, anise, etc., and its peculiar oil, *apiol*, acts in part after the manner of essential oils. Half an ounce of this oil given to a rabbit produced laborious breathing, frequent pulse, muscular debility and twitching, insensibility, coldness, and death. Given to man in doses of from 7 to 15 grains, it creates a sense of warmth at the epigastrium and of general well-being. 30, and from that to 60, grains produce a state of intoxication, with scintillations before the eyes, deafness and buzzing in the ears, staggering movements, and severe headache.

Medical Uses.—Freshly-bruised parsley-leaves are a popular remedy for the “weed,” or the engorgement of the mammae at the commencement of lactation, and for threatening abscess of these and other external glands. In like manner they are employed to dry up the milk. A decoction of parsley-root is useful in relieving *strangury* from cantharides and turpentine, and the painful micturition attending attacks of *gravel*. An infusion of the dried leaves and the juice have been used to cure *gonorrhœa*, and also *periodical fevers* and *neuralgia*; but the seeds are said to be superior to either in the treatment of intermittent fever when given in the form of a recently-prepared and strong decoction. Its repulsive smell and taste render it a very ineligible remedy, and it is now supplanted by *apiol*, to which identical therapeutic powers are ascribed. The value of this agent as an anti-periodic is no better established than that of the almost innumerable medicines which are reported to cure periodical affections. The case is different in regard to *amenorrhœa*, *scanty menstruation*, and *dysmenorrhœa*, in which its efficacy is demonstrated, whenever these affections appear to be owing to a want of activity and power in the ovarian nîsus; in a word, in all those cases for which direct emmenagogues are considered appropriate. It must not be forgotten, however, that the state in question is often subordinate to or associated with a general atony of the system, which requires for its cure tonics, hæmatics, and hygienic agents. *Apiol* has been used successfully in cases of *fetid menstruation* (*Boston Med. and Surg. Jour.*, Nov. 1880, p. 482).

Powdered parsley-seeds may be given in doses of from 10 to 15 grains (Gm. 0.60–1.00). The root should be employed in the recent state, and generally in strong infusion. *Apiol* may be administered two or three times a day in doses of 5 or 6 drops (Gm. 0.30) enclosed in gelatin capsules. In the uterine disorders above referred to the use of the medicine should be commenced four or five days before the menstrual period.

PHALARIS.—CANARY-SEED.

Fructus (Semen) canariense.—*Semence de canarie*, *Fr.*; *Kanariensamen*, *G.*

The fruit of *Phalaris canariensis*, Linné.

Nat. Ord.—Graminaceæ.

Origin.—This annual grass is indigenous to the basin of the Mediterranean, and is cultivated for its fruit, which is much used as food for canaries and other birds. 131,423 bushels of canary-seed were imported into the United States during the year 1876-77; in 1881 only 50,627 bushels.

Description.—The fruit is about $\frac{1}{8}$ inch (4 Mm.) long, ovate or elliptic, flattened, enclosed by glossy, yellowish-gray palæe, after the removal of which the fruit is smooth and brownish and internally white. It is inodorous and has a slightly bitter taste.

Constituents.—Like other graminaceous fruits, canary-seed contains starch, gluten, a little sugar, and fat; Dubuc ascertained also the presence in it of notable quantities of calcium chloride and of a brown bitter coloring matter.

Medical Action and Uses.—Canary-seed is to be ranked with other amylaceous seeds as nutritious and emollient. It is familiar as a food for birds, and has been used by man for the same purpose, alone or mixed with wheat or rye flour. In medicine poultices have sometimes been made of it.

PHELLANDRIUM.—PHELLANDRIUM.

Fructus phellandrii, P. G.—*Five-leaved water-hemlock*, E.; *Phellandrie*, *Fenouil d'eau*, Fr.; *Wasserfenchel*, G.

The fruit of *Oenanthe Phellandrium*, *Lamarck*, s. *Phellandrium aquaticum*, *Limé*.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—This biennial plant grows in swampy places and on river-banks in Europe and Northern Asia. It has pale-green pinnately dissected leaves, with ovate lobed or pinnately cleft leaflets, the submersed ones narrow and thread-like. The flowers are white, in compound umbels, with short linear involucral leaves. (See also page 451.)

Description.—The fruit is $\frac{1}{8}$ to $\frac{1}{2}$ inch (3-5 Mm.) long, ovate-oblong in shape, scarcely compressed, and narrowed above. The three dorsal ribs are broad and obtuse, the two lateral ones larger, the four grooves narrow, each with a single oil-tube, and two additional oil-tubes on the face of each mericarp. It is of a brown, and when collected in an unripe state of a blackish-brown, color, and has an unpleasant odor, recalling that of caraway, and a bitterish somewhat acrid taste.

Constituents.—Berthold (1818) obtained 1.5 per cent. of volatile oil, 7.8 of fat and wax, 4.9 of resin and other unimportant principles. Smaller quantities, .5 to .8 per cent., of volatile oil were obtained by others. According to Pesci (1883), the greater portion of the volatile oil consists of *phellandrene*, which is a levogyrate terpene boiling at 171° C. (340° F.) and polymerized by heat. Frickhinger (1839) describes the volatile oil as being brownish-yellow, limpid, of spec. grav. .86, of neutral reaction, fulminating with iodine, and possessing the odor and taste of the fruit. Distilled with potassa, the alkaline distillate contained ammonia, but no other alkaloid; 186 ounces of the recently-dried fruit yielded over 12 drachms of ammonium sulphate. The supposed alkaloid obtained by C. Fronefield (1860) was probably identical with Devay and Guillermond's (1852) *phellandrin*, which appears to be merely volatile oil; it is volatile, liquid, neutral, and soluble in alcohol, ether, and fixed oils.

Medical Action and Uses.—Five-leaved water-hemlock has been compared in its action to conium, for it is said that some animals upon eating the fresh herb lose their muscular power, and that this effect is not produced by the dried herb. The essential oil prepared from it injected into a dog's veins in the dose of 10 grains caused dyspnoea, trembling, and anxiety for several hours. The fruit appears to be stimulant, diaphoretic, diuretic, and expectorant, and without a direct or exclusive action upon the nervous system. Although recommended sometimes as a remedy for dropsy, whooping cough, intermittent fever, etc., it is chiefly in chronic *bronchitis* that the virtues of the medicine are displayed. At a time when this affection was considered a form of consumption, *phellandrium* was reputed to be a remedy for the latter disease; but it is now certain that it could be useful in tubercular phthisis in so far only as it might diminish the bronchial secretion, as it does in simple bronchitis. It shares this virtue with numerous plants whose activity is due to their essential oil, but neither it nor they can be compared in efficiency with the terebinthinate and balsamic preparations. The *dose* of the powdered fruit is from 30 to 60 grains (Gm. 2-4). An infusion, made with $\frac{1}{2}$ ounce of the bruised fruit in $\frac{1}{2}$ pint of hot water (Gm. 16 in Gm. 250), may be given in doses of 1 or 2 tablespoonfuls several times a day.

PHLORIZINUM.—PHLORIZIN.

*Phloridzin, Phlorrhizin.*Formula $C_{21}H_{24}O_{10}$. Molecular weight 436.

Preparation.—This principle has been obtained from the bark of the apple, pear, cherry, and plum tree—more abundantly in that of the root than in that of the stem. It is prepared from the concentrated decoction by setting it aside and recrystallizing with the aid of animal charcoal. It was discovered by De Koninck and Stas (1835).

Properties.—It crystallizes in fine silky prisms containing $2H_2O$, becomes anhydrous at $100^\circ C.$ ($212^\circ F.$), fuses at about $108^\circ C.$ ($226.4^\circ F.$), congeals at $130^\circ C.$ ($266^\circ F.$), and fuses again near $160^\circ C.$ ($320^\circ F.$), being then converted into an isomeric modification which is less freely soluble and crystallizable than the normal compound. Phlorizin is inodorous, bitter, neutral, colored yellow and red by sulphuric acid, and yields with ammonia, in the presence of moisture, red amorphous *phlorizein*, $C_{21}H_{30}N_2O_{13}$. Phlorizin requires about 1000 parts of cold water for solution, but is freely soluble in hot water and in 2 parts of cold alcohol; it is nearly insoluble in ether, and dissolves in alkalis, the solutions becoming yellow in contact with air. On being boiled with potassa, *phloretic acid*, $C_9H_{10}O_3$, a crystalline homologue of salicylic and anisic acids, is obtained, together with *phloroglucin*, $C_6H_6O_3$; the solution of phloretic acid is colored green by ferric chloride.

Composition.—The empirical formula of phlorizin has been given above. According to Rochleder (1869), it belongs to the salicylic series, while *isophlorizin*, an isomeric principle of apple-leaves, is classed with the benzoic compounds. Phlorizin is a glucoside, and when continuously heated with dilute mineral acids is resolved into glucose and *phloretin*, $C_{15}H_{11}O_5$, which is nearly insoluble in water, has a sweet taste, and by hot alkalis is decomposed into phloretic acid and *phloroglucin*. The latter is a sweet crystallizing compound, which is also produced from quercetin, dragon's blood, gamboge, kino, and other compounds by heating them with hydrate of potassium; Wiesner (1878) regards it as a very delicate test for ligneous tissue, with which 1 drop of its dilute solution produces a beautiful red color after the addition of a drop of hydrochloric acid.

Medical Action and Uses.—In 1862, De Ricci called attention to this substance as a substitute for quinia, and a number of physicians testified to its efficacy; but soon it became apparent that the new succedaneum was neither more nor less valuable than the numerous bitter vegetable products which act as stomachic tonics and sometimes cure cases of mild *intermittent fever*. Among these medicines it is most comparable to salicin. Phlorizin was formerly given in doses of from 10 to 20 grains (Gm. 0.60–1.30), but is now quite disused.

PHOSPHORUS, *U. S., Br., P. G.*—PHOSPHORUS.*Phosphore, Fr.; Phosphor, G.*

Symbol P. Atomicity trivalent and quinquivalent. Atomic weight 31.

Phosphorus should be carefully kept under water in a secure and moderately cool place, protected from light.—*U. S.*

Origin and Preparation.—Phosphorus exists, mostly as phosphates, in many minerals and in all plants and animals; the bones of the higher animals contain much phosphate of calcium. Phosphorus was discovered by Brandt (1669) of Hamburg among the products of the dry distillation of urine, and about 1769 Gahn and Scheele detected the presence of phosphoric acid in bones, and the latter succeeded in isolating it in 1771. Phosphorus is made by treating calcined bones with sulphuric acid, decanting from the calcium sulphate, evaporating the liquid, after mixing it with powdered charcoal, to complete dryness, and distilling the residue in a stoneware retort. In case the organic matter of bones is to be utilized in the manufacture of glue, the bones are treated with hydrochloric acid and the liquid treated as stated. The retort is connected with a wide bent tube which dips into water; a number of retorts are placed in each furnace, and after the distillation is completed the melted phosphorus is strained under water and run into tubes of suitable size, where it congeals. Phosphorus is manufactured in the United States, but much of it is still imported, the importation in 1882 amounting to 146,410 pounds.

Properties.—Phosphorus is seen in commerce in the form of cylindrical sticks, which are nearly colorless or pale-yellow, transparent or translucent, of a waxy lustre, and about as hard as beeswax, and flexible at ordinary but brittle at low temperatures.

It is inodorous and tasteless, but in contact with air it has an alliaceous odor and taste, and emits white vapors, which are luminous in the dark (phosphorescence). It is very easily inflammable in the air, burning with a brilliant white flame and giving off dense white vapors of phosphoric anhydride, and must be preserved and cut under water, in which it is insoluble. Its density, according to H. Kopp (1855), is 1.826 at 10° C. (50° F.), and when fused at 44° C. is 1.743, but after purification with alcoholic potassa was found by Böttger to be 2.089 at 17° C. (62.6° F.). It melts at 44° C. (111.2° F.), and may be cooled to 40° C. (104° F.) before it congeals again—under certain circumstances even to 4° C. (39.2° F.), as observed by Bellani (1813). Grotthuss (1810) obtained phosphorus in an oily condition after boiling it with alcoholic solution of potassa, and Kalhofert (1850) by slowly evaporating a solution of phosphorus in carbon bisulphide from under water. Houston and Thompson (1874) made similar observations with phosphorus treated with hot potassa solution, and regard this oil as a modification of ordinary phosphorus. The boiling-point of phosphorus is 288° C. (550° F.), according to Dalton; Mitscherlich found it at 260° C. (500° F.); but it volatilizes slowly with the vapors of boiling water; the density of its vapor is 4.3. According to Joubert, phosphorus is not luminous in pure oxygen below 14° C. (57° F.) unless the pressure be diminished or the oxygen is mixed with an indifferent gas; the luminosity is prevented in the presence of sulphuretted hydrogen, of vapors of alcohol, ether, and other compounds. Phosphorus is sparingly soluble in alcohol, ether, fixed and volatile oils; it dissolves “in 350 parts of absolute alcohol at 15° C. (59° F.), in 240 parts of boiling absolute alcohol, in 80 parts of absolute ether, in about 50 parts of any fatty oil.”—*L. S.* It is more freely soluble in sulphur chloride, chloroform, benzol, and abundantly so in carbon disulphide, the latter solution being extremely inflammable. Phosphorus crystallizes after fusion when slowly cooled, and from its solutions in volatile oils and carbon disulphide. It unites directly with oxygen, sulphur, chlorine, iodine, bromine, and with many metals, and precipitates some of the latter from their solutions. When kept in water and exposed to light and air it is superficially corroded, and becomes white and opaque (Baudrimont, 1865), while phosphorous acid is found in the water; the change does not take place in water which is free from air, nor does phosphorus lose its transparency when kept in the dark. Under certain conditions phosphorus, when melted and suddenly cooled, becomes black, according to Blondlot (1869). This is due to the presence of a black body which is rather more volatile than ordinary phosphorus. Commercial phosphorus frequently contains a little arsenic, from which it cannot be freed by distillation.

AMORPHOUS OR RED PHOSPHORUS. This was discovered by Schrötter (1848) by heating ordinary or vitreous phosphorus for a long time to near its boiling-point (about 240° C. = 464° F.) in an atmosphere in which it cannot burn. It is an amorphous dark-red mass or powder, becomes nearly black on being boiled with potassa solution, is insoluble in simple solvents, remains unaltered in dry air, and enters into chemical combinations less readily than the ordinary variety. According to Hittorf (1865), it has the specific gravity 2.19, is infusible, volatilizes slowly above 260° C. (500° F.), and, according to Lemoine (1867), is best converted into ordinary or vitreous phosphorus by heating to near 450° C. (842° F.) in an atmosphere of nitrogen. At the temperature stated Hittorf observed it to be converted into another modification, which forms black laminae of a metallic lustre, is less volatile even than amorphous phosphorus, but, like the latter, is gradually converted by heat into ordinary vitreous phosphorus.

Tests.—The impurities likely to be present in phosphorus are derived from the sulphuric acid used in its preparation, and are mainly arsenic and sulphur; a small proportion of the latter renders phosphorus hard and rather brittle at ordinary temperatures. “If 3 Gm. of phosphorus are digested with 24 Gm. of nitric acid and 18 Gm. of distilled water until it is completely dissolved, the solution evaporated until no more nitrous vapors are given off, then diluted with distilled water, so as to weigh about 36 Gm., and hydrosulphuric acid gas be passed through the larger portion of the liquid, heated for half an hour to about 70° C. (158° F.), and afterward until the liquid cools, there should not appear more than a trifling quantity of a lemon-yellow precipitate after the lapse of 24 hours (limit of arsenic). On adding test solution of chloride of barium to the remainder of the liquid, not more than a slight opalescence should make its appearance (limit of sulphur).”—*U. S.*

Compounds of Phosphorus.—**HYPHOPHOSPHOROUS ACID**, $\text{H}_2\text{P}_2\text{O}_5$ (molecular weight 66), is formed by boiling phosphorus with milk of lime (see page 352) and under other circumstances. In its purest state it forms a thick uncrystallizable liquid; for medicinal purposes Procter (1858) suggested decomposing 480 grains of calcium hypo-

phosphite dissolved in 6 ounces of water by a solution of 350 grains of crystallized oxalic acid in 3 ounces of water, filtering from the calcium oxalate, and evaporating to $8\frac{1}{2}$ fluid-ounces, when it contains 10 per cent. of the acid.

PHOSPHOROUS ACID, H_3PO_3 (molecular weight 82), is formed on the slow oxidation of phosphorus in moist air, and forms a crystalline deliquescent mass. If phosphorus is slowly burned with a very limited supply of dry air, *phosphorous oxide* or anhydride, P_2O_3 , is formed as a voluminous flocculent powder, which liquefies in the air by the absorption of moisture, and is gradually oxidized to phosphoric acid, or, heated in a close vessel, is decomposed into phosphoric acid and phosphoretted hydrogen.

PHOSPHORIC OXIDE, P_2O_5 (molecular weight 142), and phosphoric acid are described on page 81.

Phosphorous acid and phosphites are rarely, if ever, employed in medicine. The phosphates and hypophosphites, which are sometimes used, are described under their appropriate heads. Of other chemical compounds only phosphide of zinc has been employed.

Off. Prep.—*Acidum phosphoricum* (dilutum), *Oleum phosphoratum*, *Pil. phosphori*, *U. S., Br.*

Medical History.—The first employment of phosphorus in medicine is ascribed by some to Kinkel in 1721, and by others to Mentz in 1751. After them it was advocated from time to time during the last and the early part of the present century, and the most extravagant statements were published of its life-giving powers; but the numerous, and generally unforeseen, accidents that sometimes followed its administration caused it to be abandoned as a medicine, and to retain its interest for physicians chiefly through its operation as a poison. Within the last few years it has once more risen into notice—in a great measure, we must believe, through the influence of those chemico-physiological doctrines which still prevail and the predominant part which the nervous system holds in the medical theories of the day, and possibly also to the increased number of nervous diseases chargeable to the augmented luxury and wear and tear of modern life.

Physiological Action.—*On Animals:* Applied in substance or solution to the sound skin, phosphorus does not usually occasion other symptoms than a superficial irritation, but if the integument be broken, painful ulcers follow which are extremely difficult to heal, and the phenomena of constitutional poisoning are rapidly developed. It is a very striking fact that when phosphorus in bulk is introduced beneath the skin of animals it causes neither pain nor inflammation, and, although it gives rise to toxical symptoms, the phosphorus itself retains its transparency and does not visibly diminish in bulk. Administered internally in moderate doses to various birds and mammals, such as ducks, rabbits, dogs, pigs, etc., it plainly acts as a stimulant of the nervous system, exciting the animals to unusual activity, and in some instances developing an exaggerated sexual excitement. Continuous administration of small doses of phosphorus to dogs produces the following effects: After two or three days the animal becomes dejected, the eyes congested, the urine is passed scantily and with straining, and contains an increased proportion of urea, phosphoric and sulphuric acids, and iron (Cazeneuve); the pulse and the respiration are slower, and the temperature is higher. Subsequently the pulse and respiration grow much quicker, and the temperature rises even to 5° above the normal point. Death occurs without convulsions at the end of a week. On examination of the body the gastric mucous membrane is found ecchymosed; the liver is soft and dark, with bloody spots on the surface, and its glandular elements are in a state of fatty degeneration; the gall-bladder is distended with bile containing urea and albumen; the kidneys are in a state of fatty degeneration (acute Bright's disease), which accounts for the abnormal ingredients of the bile. One-twelfth of a grain of phosphorus being given three times a day to a dog, the animal survived 17 days. After its death a vast ecchymosis occupied the left side of the thorax, extending to the costal pleura, and even to the pulmonary in a limited space. In the right lung and in the heart were also ecchymosed spots; the pulmonary tissue was dense, dirty in color, and quite oily to the touch, and demonstrably so by microscopic examination. The liver also was slightly ecchymosed, and totally disintegrated by oily infiltration. The urine was oily and albuminous, the kidneys softened and doughy, and broken down by oily infiltration (Percy). The same lesions and symptoms essentially have been found in other animals poisoned with phosphorus. According to E. Rousseau (*Inaugural Thesis*, Univ. of Penna., 1880), fatty degeneration of the liver from phosphorus is due to the conversion of the protoplasm of the hepatic cells into granular fat, and the subsequent breaking down of those cells. The change seems to begin in the region of the hepatic veins and advance toward the

periphery of the lobules; and in each cell the nucleus is removed from its central position to the periphery of the cell. Long-continued non-poisonous doses of phosphorus occasion chronic gastritis and fatty degeneration of the stomach, liver, kidneys, heart, and other muscles, both voluntary and involuntary, and hæmorrhages in various parts of the body. It at the same time, however, appears to increase the deposit of osseous matter in the bones.

On Man: In the dose of from one-sixtieth to one-tenth of a grain phosphorus quickens the pulse, raises the temperature, promotes perspiration and urination, increases both mental and physical activity, and sometimes excites the sexual organs. But it may also soon afterwards derange the digestion, causing flatulent distension, alliaceous eructations, a coated tongue, anorexia, colic, diarrhœa, vomiting, and jaundice. The experiments of Cutler and Bradford show that doses of $\frac{1}{64}$ gr. (Gm. 0.001), gradually increased to $\frac{1}{16}$ gr. (Gm. 0.006) and given three times a day, caused diarrhœa and vomiting. After an interval of three days it was resumed in the original dose. Twenty-five days after the medicine was first taken an examination of the blood showed a marked decrease in the red and an increase in the white corpuscles. While the proportion of white to red corpuscles before the experiment was 1:690, it subsequently changed to 1:433. No clearer demonstration could be made of the chief cause of the constitutional effects of phosphorus. Sometimes the functional disturbances above described appear suddenly when the treatment has been steadily continued or when a larger and poisonous dose—of 2 or 3 grains, for instance—has been taken. But in such cases the toxic phenomena may not appear for 36 hours. The first is usually a burning pain in the stomach and vomiting of matters which are more or less luminous in the dark. The heat extends to the whole abdomen, which may be tender under pressure; the stools are loose, dark, bloody, and sometimes phosphorescent, and are voided with pain. The pulse and temperature are generally raised at first, but subsequently fall below the normal standard. Usually, there is general nervous excitement, sometimes headache, giddiness, fainting, sleeplessness, delirium, spasms, convulsions, followed by collapse, coma, coldness of the extremities, strabismus, and dilatation of the pupils. In other instances death is owing to exhaustion, the mind remaining clear. Meanwhile, from the second to the fourth day there is pain in the liver, with dark jaundice, and blood is passed by stool and in the urine, and may exude from the gums or appear in ecchymoses of the skin. The urine is albuminous. After death the interior of the body is everywhere phosphorescent in the dark; the stomach is seldom widely inflamed, but chiefly in the pyloric extremity, where there may also be some ulceration, and the organ is apt to contain a bloody liquid. Sanguineous effusions are also found in other organs. The blood is dark and thick, but, according to most authorities, not easily disintegrated, and it contains an undue proportion of tissue-waste in the form of uric acid, creatine, etc. The liver is of a light-yellow color, and it, as well as the heart, capillary vessels, and kidneys, shows more or less distinct signs of fatty degeneration. In many cases death has been caused by swallowing the tops of lucifer matches, and in one instance a lad of sixteen had a number of these introduced into his rectum. He died within a few hours in very severe pain with inflammation of the bowel (*Med. News*, xl. 544). A case is recorded in which this cause of death probably existed, although unsuspected during the patient's life (*Phil. Med. Times*, xii. 866). In it blood-dissolution, ending in apoplexy, was the principal symptom. After death general fatty degeneration was discovered. According to Daniello, the spinal marrow undergoes a similar change, resulting from inflammation. The symptoms of chronic phosphorus-poisoning—as they occur, for instance, among lucifer-match makers—are briefly these: Bronchial irritation and dyspepsia; a straw-colored or grayish tint of the skin; extreme sensitiveness to cold; formication; stiffness and numbness of the limbs; softening, abscess, and ulceration of the gums; loss, and sometimes decay, of the teeth, with caries and necrosis of the jaw-bones. Usually there is hectic fever, and if the patient continue to work in phosphorus until its effects are fully developed, he is worn out by them or dies of consumption of the lungs. In a case of poisoning with lucifer matches phosphorus was found in the body three months after death (*Virchow's Archiv*, lxxxiii. 501).

These symptoms are, in their various degrees, produced by phosphorus alone, and not by any of its alkaline compounds: its oxygen compounds occasion totally different effects, and even these are not poisonous. Phosphorus is absorbed mainly without change, and a very minute proportion of it is oxidized in the system. Its administration occasions a very small increase, if any, in the urinary phosphates; and when we remember that of these a man daily excretes not less than 54 grains, it is inconceivable that the minute

quantity in which alone it is possible to administer free phosphorus can have any marked influence upon the proportion of phosphorus compounds in the tissues. Whatever action it possesses seems fairly attributable to a molecular irritation, which, if carried too far, results in tissue-transformation and physiological death. This interpretation appears to be justified by the seemingly successful treatment of certain paralyses by extremely minute doses of phosphorus. The confident anticipations that the physical and chemical constitution of bodies would enable us to predict their therapeutic effects have found no support in the medical history of this substance, and, least of all, the notion that it supplies a deficiency of phosphorus compounds in the system.

Medical Uses.—Phosphorus has been employed chiefly in the treatment of diseases of the nervous system. It is useless, if not mischievous, in *epilepsy*. In *paralysis* following cerebral hæmorrhage or embolism, or their frequent consequence, softening, improvement may be attributed to phosphorus in the first case alone. But its value becomes more than doubtful when the tendency to spontaneous cure after this accident is borne in mind. Possibly its stimulant influence may quicken the operations of repair, but not without the risk of increasing the mischief. The same statement is essentially true of *spinal paralysis*; but as this affection is not, like the other, always associated with a substantial lesion, the cases of paraplegia benefited by phosphorus are numerous enough to deserve a certain consideration. The same statement is applicable to *locomotor ataxia*. The persistent but moderate and interrupted use of phosphorus has unquestionably in a few instances temporarily improved the power of locomotion in this disease, but it has not, any more than other remedies, effected a cure. In regard to this class of diseases it may well be said: "Phosphorus is a rapid stimulant, but it acts by causing waste, and not by increasing power; it impoverishes, and does not enrich. It momentarily galvanizes, as it were, the torpid functions, but is incapable of renewing a dilapidated constitution, or even a nervous system exhausted by chronic disease" (Gubler). Although in former years phosphorus was alleged to have cured *neuralgia*, it is only of late that it has been asserted to operate "with a rapidity, a certainty, and a permanency unequalled by the action of any other medicine in this or any other disorder" (Thompson). It is said to exhibit its virtues most conspicuously—indeed to be "apparently specific"—in *neuralgia* attended with extreme debility produced by hæmorrhage, lactation, etc. when the pain follows on exposure to cold, and especially when it affects the fifth nerve. Doses less than one-twelfth of a grain (Gm. 0.005) of phosphorus every four hours are said to be inefficient, and it is added that if relief does not ensue in twenty-four hours, it is useless to persevere in this treatment. It is singular that if the medicine possesses such remarkable powers, they should not have been recognized and described by other observers. But notwithstanding the extreme frequency and intractability of this disease, phosphorus is not usually employed by physicians who have had the largest experience in its treatment. In certain cases of *neuralgia* of the heart, or simple *angina pectoris*, it is alleged to have entirely suspended the attacks. It has been used with probable advantage in chronic *psoriasis*, *lepra*, *lupus*, etc., but can seldom be necessary unless after the failure of more usual remedies. It was also credited with the cure of *pernicious anæmia* and splenic *leucocythæmia*, but a more extended and critical inquiry proved it to be useless.

There is some reason to believe that this medicine may be serviceable in functional asthenic *amaurosis*, but in no other form of that defect of vision. In *melancholia*, and even in *dementia*, it is alleged to be useful; and still more so in that state of *nervous exhaustion* and depression which follows excessive mental or even physical fatigue. In the latter case there is a rational as well as an empirical ground for supposing that it may occasionally do good. In regard to the reputed *aphrodisiac* action of phosphorus authorities differ; for while one of its most moderate expositors (Lemaire) declares that if any power belongs to the drug it is certainly this, the most extravagant of its eulogists (Thompson) concludes that phosphorus is not an aphrodisiac, unless given in a larger dose than it is safe to employ for remedial purposes. In poisonous doses it certainly exerts this power upon man and animals, but only as a transient influence which is soon succeeded by general insensibility.

Kassowitz claims (*Zeitsch. f. klin. Med.*, vii. 36, 193) to have found in phosphorus a more efficient remedy for *rachitis* than any that has been hitherto employed; and yet he administered it in the minute dose of $\frac{1}{2}$ Mgm. (gr. $\frac{1}{128}$) a day.

In *poisoning* by phosphorus it has been usual to administer lime-water, magnesia, or charcoal, with the intention of producing a chemical combination with the two first-mentioned substances, and a mechanical mixture with the last. It should be borne in mind, however, that phosphorus does not act primarily as a corrosive poison, like several acids,

and that its local gastric lesions are quite disproportioned to those which are due to its absorption. It may also be remarked that, under ordinary circumstances, the contents of the stomach do not favor the combustion of phosphorus. Oil of turpentine has been proved by numerous experiments, and by some clinical observations, to be capable of arresting the poisonous phenomena (*Guy's Hosp. Rep.*, xli. 13). It should be administered in doses of from 15 to 30 drops every half hour for several hours, and meanwhile all albuminous and oily substances should be withheld. An agent the very opposite in its chemical properties to this hydrocarbon has recently been recommended by Percy, who claims that oxygenated water by the stomach and the inhalation of oxygen gas are the true antidotes to phosphorus, by converting it into hypophosphorous and phosphoric acids, which are comparatively innocuous. This conclusion is supported by experiments on animals. Still more recently chlorate of potassium has appeared to have an antidotal and curative effect (*Amer. Jour. of Med. Sci.*, Oct. 1882, p. 575).

The dose of phosphorus is variously stated as between $\frac{1}{30}$ and $\frac{1}{4}$ grain (Gm. 0.002–0.016). Those who have most advocated its use recommend that a first dose of $\frac{1}{18}$ grain (Gm. 0.003) should be repeated every four hours until six doses are taken. If then no improvement have occurred, the dose should be increased to $\frac{1}{12}$ grain (Gm. 0.005), and repeated in the same manner as before. Of the authorities in this matter some recommend that the medicine should be given before and some after meals. Phosphorus was originally administered in ether or alcohol, and more recently dissolved in almond oil, olive oil, cod-liver oil, glycerin, chloroform, etc., or mixed with cocoa butter, wax, soap, spermaceti, and formed into pills coated with gelatin; or, finally, in capsules containing phosphorized oil (1 : 100). Each capsule should contain 1 Mgm. ($\frac{1}{65}$ gr.) of phosphorus. The following formula has been recommended: *R.* Phosphori gr. ij; Carbon. bisulphid. q. s.; solve; Saponis, Guaiaci resinæ, āā gr. xxxv; Glycerinæ gtt. xij; Pulv. rad. glycyrrhiz. gr. xij.—*M.* ft. mass. Divide into pills of the required strength and coat with gelatin or varnish.

PHYSOSTIGMA, U. S.—PHYSOSTIGMA.

Physostigmatis semen, Br.; *Faba calabarica*.—Calabar bean, Ordeal bean, E.; *Fève de Calabar*, Fr.; *Kalabarbohne*, G.

The seed of *Physostigma venenosum*, Balfour. *Trans. Roy. Soc. Edinb.*, xxii. tt. 16, 17; Bentley and Trimen, *Med. Plants*, 80.

Nat. Ord.—Leguminosæ, Papilionacæ.

Origin.—This plant is a woody climber growing near the mouths of the Niger and of Old Calabar River in Western Africa, and attaining a length of 40 or 50 feet (12 or 15 M.). It somewhat resembles the scarlet runner or Spanish bean of our gardens. The purple flowers are in pendulous racemes, originating from tubercular knots to the number of two or three. The curved style bears at its apex a triangular fleshy reflexed appendage. The pale-brown, reticulately-veined legumes contain two or three seeds. The plant was described by Balfour in 1861, and has been introduced into India and Brazil.

Description.—The seeds are 1 to $1\frac{1}{4}$ inches (25–31 Mm.) long, about $\frac{5}{8}$ inch (16 Mm.) broad, and $\frac{1}{2}$ inch (12 Mm.) thick, oblong and more or less reniform in shape. A well-marked black furrow, the hilum, with a ridged border, extends along the convex edge from one extremity of the seed to the other, and contains in the centre the thread-like raphe. The seed has a brittle, somewhat polished, granular testa of a chocolate-brown color, two white cotyledons adhering to the testa and concave upon the inner surface, thus enclosing a rather large cavity; along the hilum each cotyledon is marked with a long shallow groove. The short radicle is situated at one end, and its position is externally indicated by the small depressed micropyle. Calabar beans are inodorous, but on the evaporation of the tincture an odor resembling that of cantharides is given off. Their taste is nearly like that of the ordinary bean. On being moistened with potassa solution the cotyledons become pale-yellow.

The seed of another species was observed by Holmes (1879) among the commercial drug. The plant was described by Oliver as *Mucuna cylindrosperma*, *Wulfsch.*, but should evidently be called *Physostigma cylindrosperma*. The seeds are about $1\frac{1}{4}$ inches (44 Mm.) long, nearly cylindrical, of a dark reddish-brown color, and have a shorter hilum, not extending quite to the end where the micropyle is visible. The cotyledons acquire with alkalies a deep-yellow color.

Constituents.—The poisonous principle of Calabar bean is the alkaloid *physostigmine*, which was isolated by Jobst and Hesse (1864), and by the latter (1867) ascer-

tained to have the composition $C_{15}H_{21}N_3O_2$. Vée (1865) proposed to call the alkaloid *eserine*. It is obtained by mixing powdered Calabar bean with 1 per cent. of tartaric acid, exhausting with alcohol, evaporating the solvent, treating the residue with water,

Phys. cylindrospermum seed.

agitating the filtrate with ether as long as the latter becomes colored, then supersaturating with potassium or sodium bicarbonate, and again agitating with ether; on evaporating the ether, physostigmine is left behind in a colorless, amorphous condition. The crystals obtained by Vée were isolated by Hesse (1877) and found to be *physosterin*, an indifferent body resembling cholesterin, and crystallizing from ether, chloroform, and petroleum benzin in silky needles, and from hot alcohol in scales. Physostigmine becomes soft at $40^{\circ} C.$ ($104^{\circ} F.$), and is liquid at $45^{\circ} C.$ ($113^{\circ} F.$); it is readily soluble in alcohol, ether, benzol, carbon bisulphide, and chloroform, less freely so in water, and neutralizes acids completely; it even precipitates ferric hydrate from a solution of ferric chloride. The pure alkaloid and its salts are tasteless; their solutions yield with Mayer's reagent a white precipitate which is readily soluble in ether and alcohol and crystallizes from the latter in prisms. Physostigmine is colored red by chlorinated lime, and becomes colorless again by more of the reagent. Nitric acid dissolves the alkaloid with a yellow color, sulphuric acid with yellow, turning olive-green. On adding excess of ammonia to the solution of a salt and heating the mixture upon a water-bath, the liquid turns successively red, orange-red, yellow, green, and blue. Alkalies color solutions of physostigmine red, producing the *rubreserine* of Duquesnel, and if now agitated with ether the ethereal solution will become blue or red on the addition of dilute sulphuric acid, the color depending on the degree of decomposition undergone by the alkaloid. Rubreserine crystallizes from its solution in chloroform, and, according to Harnack and Witkowski (1880), is insoluble in pure ether: its red color disappears in presence of sulphurous acid, but reappears on the evaporation of the latter. **PHYSOSTIGMINA** is official in *Br. P.*

Harnack and Witkowski (1876) succeeded in isolating a second alkaloid, *calabarine*, which produces tetanic effects in cold-blooded animals. It is obtained from the liquid from which physostigmine has been separated by precipitating it with subacetate of lead and ammonia, evaporating the filtrate, treating the residue with alcohol, precipitating with phosphotungstic acid, and decomposing with baryta. This alkaloid is soluble in alcohol and water, insoluble in ether, and its mercuric double iodide is insoluble in water and alcohol. Subsequently (1880) the same authors ascertained that calabarine is formed in solutions of physostigmine; for instance, under the long-continued influence of hydriodic acid.

According to Teich (1867). Calabar bean contains 48 per cent. of starch, 3.65 of nitrogen, indicating about 23 per cent. of proteids, and 3 per cent. of ash, chiefly phosphate of potassium. Mucilage and a small quantity of fat are likewise present. The alkaloids appear to exist mainly in the cotyledons, but the testa likewise possesses medicinal activity.

Adulterations of Calabar bean have not been observed by us. The seeds of a *Mucuna* (*cylindrosperma*?) and of the oil palm have been mentioned, but bear no resemblance to the official article.

Off. Prep.—*Extractum physostigmatis, U. S., Br.; Tinct. physostigmatis, U. S.*

Physiological Action.—*On Animals:* After a small but fatal dose a slight tremor seizes the animal, beginning in the posterior region and advancing forward; paralysis

follows in the same order of parts; the bowels are apt to be evacuated and the pupils contract. Respiration becomes stertorous during inspiration and expiration, as well as slow and irregular. Slight muscular twitches appear and reflex action is annihilated, but while the sense of pain is lost tactile sensibility and the muscular sense are unimpaired. The rate of the heart-beat declines, but the power of the systole increases until the approach of death, when it also subsides. Death does not take place by the heart unless the dose of the poison have been very great, but is brought about by muscular paralysis of the respiratory apparatus, destroying life by an accumulation of blood in the lungs and asphyxia. Immediately after death the pupils dilate; muscular contractility is retained for some time longer; the heart may continue to act for an hour or more, and the intestines may exhibit their peristaltic movements. The large veins of the thorax are distended, as are also those upon the surface of the brain; the vascular system of the spinal cord appears natural. When a large fatal dose is given the right and left sides of the heart and the arteries and veins, which everywhere remain well filled, present their characteristic differences of color. The peculiar tremor above referred to may be produced in dogs by the hypodermic injection of $\frac{1}{5}$ grain of eserine. It may be exaggerated into distinct spasmodic movements, and even general convulsions. Vomiting is usual, and salivation also, with a frothy bronchial secretion, frequent urination, and fecal discharges, which become more and more liquid. When the poison is applied directly to a part concerned in the function of motility, it occasions paralysis of the organ. On the brain itself it exerts no action, but through the spinal cord it first occasions a few twitches in the limbs, followed by their paralysis. In direct contact with an insulated nerve-trunk, it paralyzes the afferent fibres first, and then the efferent. On or in the heart, it arrests the action of the organ, and applied to the capillary blood-vessels it causes their dilatation. Hiller observed the action of physostigma upon the exposed intestines of animals. The most characteristic effect was a circular tetanic contraction of the bowel, while its peristaltic motion was impaired, and then suspended, and the tissues grew pale. It never caused fecal evacuations unless the rectum were filled with feces (*Centralblatt f. Therap.*, i. 188).

On Man (for a fuller account of this substance as an "ordeal bean" see STILLE, *Therapeutics*, etc., 4th ed., ii. 320): In excessive but not fatal doses physostigma causes pallor of the skin, giddiness, weakness and faintness, indistinctness of vision, contraction of the pupils, nausea or vomiting, an accumulation of liquid in the mouth, a feeble but rapid and tumultuous action of the heart, and a total inability to perform voluntary muscular acts. The muscles twitch, but there is a complete absence of pain in them and elsewhere. The contraction of the sphincters caused by it has induced retention of urine. In a few fatal cases of poisoning by this substance the following characteristic effects have been observed: Extreme muscular relaxation and debility, salivation, urgent nausea and vomiting; a slow, feeble, and almost insensible pulse, with coldness of the extremities and of the skin, which is covered with a cholera-like sweat. Some colic may be felt at first, but generally no pain is experienced, although a distressing oppression of the chest is complained of. The pupils are not usually contracted. There is much vomiting and purging, the respiration is rattling, and the face livid. Consciousness remains until death, which occurs without a struggle. On dissection the body presents no characteristic lesions, unless it be a fluid condition of the blood, which also distends the heart, a flaccid state of the muscles, and some pale injection of the gastric mucous membrane. Investigations post-mortem, taken together with the action of physostigma when applied locally, seem to render it probable that the whole chain of toxical phenomena occasioned by this substance is more readily explained by its immediate action upon the muscles or upon the nervous branches supplying them than by its operation upon the spinal axis. This conclusion is supported by the results of its direct application to the eye. It then produces a marked contraction of the pupil, which may last in a high degree for twelve or fourteen hours, and less conspicuously for several days. But the effect is confined to one eye if the application is limited to one; and if it be made also to the corresponding eyelids, they become paralyzed, but no general symptoms are exhibited. It seems probable that pupillary contraction by this substance is due to its dilating the blood-vessels of the iris, just as dilatation of the pupil by atropine is caused by its power of contracting the same blood-vessels. It is true that Falek states as the inevitable inference from experiments that physostigmine (eserine) acts as a stimulant upon the sphincter muscle of the iris (*Antagonismus der Gifte*, 1879). It is also true that neither of these antagonistic explanations affects the fact that eserine contracts the pupil.

The toxical action of physostigma is sometimes induced by very small doses of the

drug. Hiller speaks of cases in which it occasioned retention of the urine while it promoted defecation. Contraction of the pupil, with a sense of tension in the eyeballs and heaviness of the head, was usual. In a feeble, anæmic woman, after using one-fortieth of a grain (Gm. 0.0015) of the extract in the course of two days threatening symptoms arose, comprising violent palpitation of the heart, præcordial distress, and irregular and rapid pulse; there was also gasping for breath, shallow respiration, and an earthy hue and slight cyanosis of the face (*Zeitschrift f. k. Med.*, vi. 490).

Medical Uses.—Physostigma is frequently employed to contract the pupil: for example: "In *mydriasis* dependent upon the over-action of belladonna or as a symptom of amaurosis; in *iritis* and inflammation of the neighboring structures, where the prevention of adhesions may be more successfully secured by an alternation of contraction and dilatation than by dilatation alone; in injuries of the eyeball with displacement of the iris, etc." It favors the healing of *corneal ulcers*, such as so frequently occur in strumous children, and are accompanied with extreme photophobia that maintains a constant irritation of the eye; and when perforation of the cornea occurs it also prevents *prolapse of the iris*. Even when this accident takes place, eserine is the best agent for extricating the hernia of the iris. Sometimes the alternate action of atropine and eserine is better than that of either alone. In *photophobia* depending upon asthenia, and therefore on irritability of the nerves of the eye, eserine is very useful, and may render the employment of shades, dark rooms, etc. superfluous. It is equally so in *paralysis of accommodation of the iris*, such as follows diphtheria and other debilitating disorders. In the opinion of ophthalmologists eserine is a valuable palliative of *glaucoma*. It combats "the particular displacement of the iris which is often the cause of the tension" (Priestley Smith), but is not in any sense a substitute for the operation of iridectomy. The operation of *iridectomy* is facilitated by the tension and increase of surface which the iris, under the use of this medicine, presents. *Night blindness* has been successfully treated by instillations of a solution of eserine, which is supposed to act by augmenting the vascularity of the retina. When the sight is impaired by paralytic dilatation of the iris this medicine is a useful palliative of the defect. Of all the medicines which have cured *tetanus*, physostigma certainly holds the first place. In 1874 an analysis of published cases showed that out of sixty-three cases of traumatic tetanus treated by this medicine thirty-three recovered. Since then this unusual proportion of cures of a disease which was before nearly always fatal has been considerably increased. When the treatment has failed, as has often happened, the failure has been mainly attributable to an inefficient use of the remedy, but sometimes also to its employment having been too long delayed. The more recent experience of its use in tetanus fully confirms the judgment here expressed (1884). The minimum dose of extract of physostigma which should first be administered is $\frac{1}{4}$ grain (Gm. 0.02). It should be repeated every quarter of an hour until its specific operation is developed and the spasms are completely overcome. This effect should be steadily maintained, and then reproduced as often as spasms recur. It is usually necessary to increase the dose in order to maintain the original impression. Several German physicians have used this agent to overcome passive dilatation of the intestine, especially in cases of fecal accumulation. Subbotin used for this purpose the following: *R.* Ext. physostigmat. Gm. 0.10 (gr. $\frac{1}{4}$); Glycerin, Gm. 20.0 (fl. 5v). *Dose*, 10 drops. An objection to the medicine is, that its action is likely to continue longer than necessary, and also that it leaves the bowel more confined than at first. Hiller has suggested that in epidemic *cholera* this spastic action of the drug might be utilized to prevent the colliquative discharges, or rather the profuse secretion that produces them. But the method seems too mechanical. Moreover, it could only have a chance of acting in the early stage of the attack. In a tetanoid disease known as *tonic convulsion* the medicine has also been successfully employed. Its efficacy in *strychnine-poisoning* is not so well established, and in *chorea* it so generally fails that its use is hardly warrantable unless in very prolonged and obstinate cases.

The physiological antagonism between physostigma and belladonna has been illustrated by the neutralization of the poisonous effects of the latter by the former medicine. But as fatal *poisoning by belladonna* is exceedingly rare, the practical value of the antidote is very small. That poisoning by physostigma is neutralized by the hypodermic injection of atropine has been abundantly demonstrated by experiments upon man. The antagonism is not so evident in similar experiments upon rabbits.

Physostigma has been found useful internally as a palliative of *gastralgia*, and topically its tincture is distinctly anodyne in *neuralgia* and *muscular rheumatism* and in cases of painful malignant *tumors*.

As antidotes to the *poisonous effects of physostigma*, atropine should be used hypodermically, while coffee and alcoholic and other diffusible stimulants are internally administered. If the patient is unable to swallow, artificial respiration should be maintained, mechanically as well as by means of induced electricity, and the use of atropine persisted in. The hypodermic dose of the latter should not be less than $\frac{1}{30}$ grain (Gm. 0.002).

Administration.—The commencing dose of the powdered bean is about 1 grain; of the official extract, about $\frac{1}{10}$ grain (Gm. 0.006); of the official tincture, about 10 minims. For external use a solution of 1 part of the alcoholic extract in 5 parts of glycerin has been employed. For application to the eye this solution is applied on little disks of gelatin or of paper that have been soaked in it. Eserine may be applied to the eye in its original state, or as a hydrochlorate in a solution containing 1 part to 1000. Internally, it may be given in the dose of from $\frac{1}{65}$ to $\frac{1}{12}$ grain (Gm. 0.001–0.005).

Doundaké (said to be a shrub of the Rubiaceæ family, and found on the western coast of Africa), and its organic base *doundakine*, given to frogs hypodermically, produce either a paralytic or a cataleptic condition, and kill by suspending the respiration without affecting the heart (*Med. News*, xliii. 265). The bark has a very bitter taste, and is employed by the natives as a febrifuge.

In 1880, Tamret described the effects of cedrine and valdivine, the active principles of the fruits of *Simaba cedron* and *Picroleuma valdivia*, products of Colombia, S. A. *Valdivine* has been found by Dujardin-Beaumetz and Restrepo to be a mortal poison to rabbits and dogs. It is peculiar in the slowness with which its symptoms are developed even when used in fatal doses. In dogs it causes violent and persistent vomiting, and in rabbits a deep torpor, which continues until death, and is not attended with convulsions. In man doses of $\frac{1}{16}$ grain (Gm. 0.004) occasion vomiting at the end of half an hour. It was found useless in counteracting the effects of poisonous *serpent-bites*, but in *hydrophobia* it prevented the convulsions that usually precede death. It does not seem to influence the course of intermittent fever. *Cedrine* is much less poisonous than valdivine. It has “unquestionable *anti-periodic* virtues, although they are feebler and slower than those of quinine” (*Bull. de thérap.*, c. 328).

PHYSOSTIGMINÆ SALICYLAS, U. S.—SALICYLATE OF PHYSOSTIGMINE.

Physostigminum (Eserinum) salicylicum, P. G.—*Salicylate of eserine*, E.; *Salicylate d'éserine*, Fr.; *Physostigmin-Salicylat*, G.

Formula $C_{15}H_{21}N_3O_2C_7H_6O_3$. Molecular weight 413.

The salt should be kept in small, well-stopped vials in a dark place.—U. S.

Preparation.—Dissolve 2 parts of physostigmine and 1 part of pure salicylic acid in 35 parts of boiling distilled water; strain if necessary, and set aside to crystallize (Hager).

Properties.—The salt forms colorless glossy needles or prismatic crystals, which in the dry state remain unaltered for a long time even on exposure to light, but ultimately turn reddish; which change is hastened by the presence of ammoniacal vapors; its aqueous and alcoholic solutions, however, become reddish in the course of several hours after exposure to diffused daylight, though the change occurs less rapidly than with other salts of physostigmine. The salicylate is neutral, and dissolves at 15° C. (59° F.) in 12 parts of alcohol and in 130 (Hager, U. S. P.) or 150 (P. G.) parts of water, and at the boiling temperature in about 30 parts of water, and in much less alcohol. The aqueous solution of the salt acquires a violet color on the addition of a little ferric chloride, and if sufficiently concentrated produces with sulphuric acid a white precipitate of salicylic acid. The alkaloid is recognized by decomposing the aqueous solution with sodium bicarbonate and agitating with ether: the amorphous residue left on evaporating the ethereal solution should show the reactions described under PHYSOSTIGMA.

Tests.—The salt should have the properties described above, and on being heated on platinum-foil should burn, without leaving any residue. The solution in strong sulphuric acid is at first colorless, but becomes yellow.

Other Salts.—PHYSOSTIGMINÆ SULPHAS, Sulphate of physostigmine, $(C_{15}H_{21}N_3O_2)_2H_2SO_4 \cdot 7H_2O$. It is with difficulty obtained in crystals, is usually an amorphous mass, and, being rapidly colored on exposure and very deliquescent, is not adapted for medicinal use.

PHYSOSTIGMINÆ HYDROBROMAS, Hydrobromate of physostigmine. It is crystalline, more staple than the preceding salt, but inferior in this respect to the salicylate.

Action and Uses.—The salicylate is said to be less liable to decomposition than the other salts of physostigmine. If it is intended especially for hypodermic use, its difficult solubility in water and its changes under the action of light render it of doubtful value in a permanent solution. It is probably better adapted for solution in alcohol and water for instillation into the eye. It may be given hypodermically in doses of from one sixty-fifth to one-twelfth of a grain (Gm. 0.001–0.005). But Lewin gives Gm. 0.001 as the maximum dose.

PHYTOLACCÆ BACCA, U. S.—PHYTOLACCA-BERRY.

Pokeberry, E.; *Raisin d'Amérique*, Fr.; *Amerikanische Kermesbeere*, G.

The fruit of *Phytolacca decandra*, Linné.

PHYTOLACCÆ RADIX, U. S.—PHYTOLACCA-ROOT.

Poke-root, E.; *Racine de phytolaque*, Fr.; *Kermesbeerenwurzel*, G.

The root of *Phytolacca decandra*, Linné.

Nat. Ord.—Phytolaccaceæ.

Origin.—Poke or garget is a perennial herb indigenous to North America and naturalized in the West Indies and Southern Europe. It grows in waste places, and has a smooth stem 4 to 8 feet (1.2–2.4 M.) high, alternate petiolate, ovate-oblong acute leaves, and white decandrous flowers in elongated racemes, which are usually opposite the leaves. The young shoots collected in early spring are sometimes eaten as a substitute for asparagus. It commences to flower in June, and ripens its fruits in August, when the root and berries should be collected. The young shoots of *Phyt. octandra*, Linné, indigenous to Central and South America, and *Phyt. acinoso*, *Roxburgh*, a native of Northern India, are likewise eaten.

Description.—1. **THE ROOT.** In the fresh state the root is large, conical, branched, and fleshy. In commerce it is seen in transverse or longitudinal slices, from 1 to 4 inches (2–10 Cm.) in diameter, longitudinally wrinkled, yellowish brown-gray externally, hard, and breaking with a fibrous fracture. It is of a dingy white color internally, and exhibits upon transverse section a number of circles composed of wood-tissue radially divided by numerous medullary rays and concentrically approximate, being separated from one another by shrunken parenchyma, which in the fresh state is fleshy and of about the width of the wood-circles. The root is inodorous; its taste is at first sweetish, afterward somewhat acid.

2. **THE FRUIT** is a flattened globular compound berry, about $\frac{1}{8}$ inch (8 Mm.) in diameter, and composed of ten carpels, which are concentrically arranged around a short axis, are laterally confluent, and contain each one lenticular black and shining seed, with the embryo curved around a mealy albumen. The fruit is of a dark-purple color, has a thin pericarp, and contains a purplish-red juice which is inodorous and has a sweet and slightly acid taste. When the berries are dried on their common peduncles they have a slight resemblance to raisins.

Constituents.—The root was analyzed by E. Donnelly (1843) and W. F. Pape (1881), who found starch, tannin, resin, and other common constituents of plants, but did not succeed in isolating the active principle. Pape's observation renders the presence of an alkaloid probable; he obtained 10.7 per cent. of ash, two-thirds of which was soluble in water. Terreil (1881) obtained amorphous *phytolaccic acid*, which is soluble in water and alcohol, reduces silver salts, and yields with earths and alkalis soluble salts, from which boiling hydrochloric acid separates the acid as a jelly. Reichel's analysis (1836) of the root of *Phytolacca* (*Pircunia*, *Beteso*) *drastica*, *Pöppig*, yielded similar results; among the salts was found 6.6 per cent. of calcium malate. The fruit was examined by Braconnot (1804); its coloring matter is bleached by sunlight and turned yellow by alkalis. W. Cramer (1881) showed the presence of sugar, gum, and malic acid, and found the fresh fruit to contain 70 per cent. of moisture and the dried fruit to yield 5 per cent. of ash, of which 62 per cent. was soluble in water. E. Classon (1879) obtained from the seed *phytolaccin*, which is soluble in alcohol, ether, and chloroform, slightly so in benzin, and insoluble in water; it crystallizes in colorless needles, is tasteless, and dissolves in sulphuric acid with a brown-yellow, and in warm nitric acid with a yellow, color. The

FIG. 211.

Poke-root: transverse section.

fruit of most other species of *Phytolacca* contains a similar coloring matter. According to Landerer (1836), the juice is employed in Turkey for coloring sweetmeats.

Physiological Action.—Although long known to possess certain acrid and narcotic properties, *phytolacca* has never been generally employed as a medicine. The juice or a strong decoction of the root applied to the skin when abraded or tender causes a smarting or burning pain, and it is reported that a person engaged in powdering the root suffered from coryza, headache, purging, and prostration. Vomiting and purging are said to have followed eating the flesh of pigeons that had fed upon the berries, but it is well known that pigeons and other birds which feed on these berries are eaten without harm. The young shoots are eaten boiled, like asparagus and cabbage-sprouts. The powdered root is emetic and purgative in the dose of 1 or 2 drachms, and 2 teaspoonfuls of the juice of the root have produced similar effects. It is remarkable that the evidences of gastro-intestinal irritation do not arise until an hour or two after the medicine has been taken. In an overdose, besides vomiting and purging and intense thirst, with epigastric distress, it affects the nervous system, causing great prostration, coldness of the skin, and even a cyanotic discoloration, feebleness of the pulse, drowsiness, vertigo, dimness of vision, coma, and sometimes convulsions. In the case of a child six years old they assumed the tetanic form. This patient recovered, but the death of an adult female from eating the berries is recorded. None of these effects are produced even by 30-grain doses of the powdered root. According to Rutherford, the resin of *phytolacca* is "a mild intestinal but a powerful hepatic stimulant"—a conclusion the first part of which does not apply to the root of the plant.

Medical Uses.—The most probable evidence in favor of the medicinal powers of this plant relate to its use in *rheumatism* and in *diseases of the skin*. In the former, and especially in *syphilitic rheumatism*, it has been employed as a tincture either of the root or of the berries and as a decoction of the former, and is reputed to have displayed anodyne and sudorific powers. The decoction, the tincture, the juice of the leaves, etc. have been used extensively and with reputed advantage, both internally and locally, in the treatment of sanious *ulcers*, *scabies*, *tinea capitis*, *sycosis*, and *farus*, and of the *mange* in dogs. An ointment made with the roots or leaves (3ij to lb. j lard) has been applied in the same affections. All of these preparations have been much employed in the treatment of *hemorrhoids*, and the infusion and decoction both internally and by injection. The decoction has been administered with alleged benefit in *scrofula*, as well as used locally in treating the ulcers peculiar to that disease. It has been alleged to prevent and also relieve mammary inflammation after delivery, and to cure "irritation of the ovaries with uterine complications," but the statements are too vague for acceptance.

In the action and medicinal uses of *phytolacca* it is difficult to avoid observing a certain analogy between it and *dulcamara* on the one hand and white hellebore on the other. The dose of the powdered root as an emetic is from 10 to 30 grains (Gm. 0.60–2). Of a saturated tincture about a fluidrachm (Gm. 4) may be given two or three times a day. An ointment may be made by mixing with an ounce of lard the extract produced by evaporating an ounce of the tincture.

PICHURIM.—PICHURIM BEANS.

Fèves pichurim, *Noix de sassafras*, Fr.; *Pichurimbohnen*, *Sassafrasnüsse*, G.

The cotyledons of *Nectandra* (*Ocotea*, *Martius*) *Puchury major* and *N. Puchury minor*, *Nees*.

Nat. Ord.—*Lauraceæ*.

Origin.—Both species are Brazilian trees, with ovate smooth leaves and elliptical drupaceous one-seeded fruits, which are surrounded at the base by the hardened involucre. The embryo only is used, and is dried by artificial heat.

Description.—The so-called pichurim beans consist of the cotyledons, which are rarely united. They are oblong or roundish ovate, convex and blackish-brown on one side, nearly flat or concave and lighter colored on the other side, and near one end with a depressed scar left by the detached radicle. The large pichurim beans are from 1½ to nearly 2 inches (4–5 cm.) long; the small rarely exceed ¾ inch (18 Mm.), and are often covered on the convex side with the pale-brown finely-wrinkled integuments. Both have internally a light-brown color, with yellowish oil-cells, and have an aromatic odor and taste, resembling that of nutmeg with an admixture of sassafras.

Constituents.—Kobes (1800) obtained from the large variety 2.1. and Bonastre (1821) from the small variety 3. per cent. of pale-yellow volatile oil; the latter also 10

per cent. of a brown butyraceous and 22 per cent. of a solid fat. Sthamer (1845) extracted the soft fat by cold alcohol, and the solid kind by boiling with alcohol and expressing; the latter is laurin. Alex. Müller (1853) separated the volatile oil by fractional distillation into a colorless pungent oil, boiling at 150° C. (302° F.); a colorless oil of an orange-like odor, boiling near 170° C. (338° F.); a yellowish-green portion, having the odor of pichurim, and boiling near 240° C. (464° F.); and a considerable quantity of a dark-blue oil, boiling near 260° C. (500° F.) and containing a little lauric acid. All the fractions contain oxygen. Pichurim contains also starch, gum, and other common vegetable principles.

Medical Action and Uses.—Introduced a century ago into Europe by the Portuguese, pichurim beans were for a long time regarded as possessing a great medicinal value, and even very recently were included in the officinal lists of the German, Spanish, and Portuguese Pharmacopœias. They appear to depend for their virtues upon a concrete volatile oil, and are sometimes used as substitutes for nutmeg. They have been chiefly used as stimulants and tonics in mild, subacute, and chronic *diarrhœa* and *dysentery*, and in habitual debility of the intestinal canal tending to produce flatulence and diarrhœa. Pichurim-bark, which has an aromatic smell resembling that of nutmegs and an astringent taste, is employed in Panama in the treatment of *typhoid states* of the system, in atonic *dyspepsia*, *chronic vomiting*, *intermittent fever*, and *menstrual disorders*. The beans are given in powder in doses of from 10 to 20 grains (Gm. 0.60–1.30), or else in an infusion; the bark is used in the same manner and in doses twice as great as these.

PICROTOXINUM, U. S.—PICROTOXIN.

Picrotoxine, Fr.; *Pikrotoxin*, G.

Formula $C_9H_{10}O_4$. Molecular weight 182.

A neutral principle prepared from the seeds of *Anamirta paniculata*, *Colebrooke*, s. *Anam.* (*Menispermum*, *Linné*) (*Cocculus*, *Wight et Arnott*, s. *Cocc. suberosus*, *De Candolle*. *Bentley and Trimen*, *Med. Plants*, 14.

Nat. Ord.—*Menispermaceæ*.

Origin.—*Anam. paniculata* is a tall climbing shrub, with broad heart-shaped leaves and long drooping racemes of small greenish dioecious flowers, indigenous to India and some of the East Indian islands. The fruit, which is an article of commerce, and of which 327 pounds were imported in 1867, is known as

COCCULUS INDICUS, s. *Fructus cocculi*.—Fishberries, *E.*; *Coque du Levant*, *Fr.*; *Kokkelskörner*, *Fischkörner*, *G.*—It is globular, kidney-shaped, about $\frac{1}{4}$ inch (6 Mm.) in diameter and $\frac{2}{5}$ inch (10 Mm.) in length, blackish-brown and wrinkled. The base and apex of the fruit are close together on one side of the fruit, separated from each other by a shallow sinus and connected by an obscure ridge running around the convex side. The endocarp or shell is whitish, thin, and on the narrow concave side folded inward, forming a double projection into the interior of the fruit, and causing the embryo to assume a semilunar shape upon longitudinal section. The fruit is inodorous and almost tasteless, with the exception of the shrivelled oily embryo, which is disagreeably bitter. *Cocculus* differs in the characters described from all other fruits usually met with in drug-stores. According to Schmidt and Rolmer (1883), the fruit contains 23.6 per cent of fat, over one-third of which is free stearic acid. Pelletier and Couërbe (1833) isolated from the integuments of the fruit the crystalline and tasteless alkaloid *menispermine*, $C_{18}H_{21}N_2O_2$, and *paramenispermine*, which has the same composition, but differs from the former in being insoluble in ether, sublimable, and in failing to neutralize acids. These bodies are associated with the amorphous brown *hypopierotoxic acid*, which is insoluble in ether and water. The poisonous principle picrotoxin is contained in the kernel, and was first isolated by Boullay in 1819.

Preparation.—Bruised *cocculus indicus* is exhausted by boiling alcohol sp. gr. .85; the tincture is concentrated by distillation to about one-third the weight of the fruit; after cooling, the fat is removed and the residue boiled with one-half its weight of water; the decoction is filtered while hot, the filtrate slightly acidulated and crystallized; the crystals require to be purified from hot alcohol. The portion insoluble in water contains *menispermine*, *paramenispermine*, and *hypopierotoxic acid*.

Properties.—Picrotoxin is in "colorless, flexible, shining, prismatic crystals, per-

FIG. 212.

Cocculus indicus: fruit and longitudinal section.

manent in the air, odorless, having a very bitter taste and a neutral reaction; soluble in 150 parts of water and in 10 parts of alcohol at 15° C. (59° F.), in 25 parts of boiling water, and in 3 parts of boiling alcohol; also soluble in acids and in solutions of the alkalies. When heated to about 200° C. (392° F.) the crystals melt, forming a yellow liquid; when heated on platinum-foil they char, and are finally completely dissipated. Concentrated sulphuric acid dissolves picrotoxin with a golden-yellow color, which turns violet-red on the addition of a trace of bichromate of potassium. When mixed with three times its weight of nitrate of potassium, moistened with sulphuric acid, and then treated with strong solution of soda in excess, picrotoxin assumes a brick-red color of short duration. The aqueous solution should remain unaffected by solutions of salts of mercury or platinum, tannic acid, iodide of mercury and potassium, or other reagents for alkaloids (absence of and difference from alkaloids).”—*U. S.*

The reaction with sulphuric acid and a trace of potassium bichromate was described by H. Koehler (1867) as giving a violet-blue color, changing to violet-brown, brown-green, and finally apple-green; excess of bichromate causes a red-brown, then dark-brown, color (W. Schmidt, 1862). The yellow color produced by sulphuric acid disappears on the addition of nitric acid. Picrotoxin dissolves in strong nitric acid to a colorless liquid, which becomes mahogany-brown with a little potassium bichromate. Heated with Fehling's solution, picrotoxin yields a precipitate of cuprous oxide (Ludwig), but is not a glucoside. Warm alkaline solutions occasion also a reduction of silver and gold salts. The reaction with potassium nitrate, sulphuric acid, and soda was suggested as a characteristic one by J. W. Langley (1862).

Diluted acids do not increase the solubility of picrotoxin in water (Pelletier, Koehler), but caustic alkalies render it much more soluble; hence Pelletier and Couërbe regarded it as *picrotoxic acid*; the alkaline solutions are, however, precipitated by carbonic and other acids. Picrotoxin is soluble in strong acetic acid, also in amylie alcohol, benzol, chloroform, ether, and in fixed oils (Koehler).

The above formula is that of Paterno and Ogialora (1877). By fractional crystallization from benzol Barth and Kretschy (1880) separated picrotoxin into three bodies. One, for which the name picrotoxin was retained, melts at 201° C. (394° F.), answers in the main to the above description, and has the composition $C_{15}H_{16}O_6 + H_2O$. The second, *picrotin*, $C_{25}H_{30}O_{12}$, has similar properties, but melts at 250° C. (482° F.), is less freely soluble in benzol, and is not poisonous. The third compound, *anamirtin*, $C_{19}H_{24}O_{10}$, remains in the mother-liquor on recrystallizing picrotoxin from water; it is but slightly bitter, is not poisonous, and its alkaline solutions do not reduce metallic salts.

Physiological Action.—*On Animals:* Cocculus is familiarly used for catching fish by mixing the bruised fruit with dough and scattering it on the water. The animals, after whirling round, lie motionless upon the surface of the water. In dogs and other quadrupeds it occasions dulness, muscular tremor, convulsion, and tetanic spasms by turns, the body being strongly bent in opisthotonos. After death no distinctive lesions are found. The poisonous effects of picrotoxin on vertebrate animals are described as exhibiting the phenomena of the epileptic paroxysm. They may be ushered in by a cry, and begin by tremor of the muscles of the head and face, which extends to those of the remainder of the body. There is unconsciousness, with tonic and clonic convulsions, discharge of urine, rotation of the eyeballs, projection of the tongue, arrest of breathing and of the heart. Invertebrate animals do not become convulsed by its use (*Bull. de thérap.*, ci. 137; *Med. Record*, xxiii. 650). Picrotoxin appears to differ from strychnine in its effects by producing alternate clonic and tonic spasms and by occasioning vomiting. They agree in exerting their power chiefly, if not exclusively, upon the spinal motor functions. It appears, however, that picrotoxin does not exalt the reflex irritability of the spinal cord as strychnine does. The minimum fatal dose for a rabbit weighing 3 pounds was found to be $\frac{1}{20}$ grain (Gm. 0.003), and its lethal effects were preventable by chloral (Browne). (Compare Roeber, *Glasgow Med. Jour.*, i. 361.)

On Man: Its chief effects in excessive doses appear to be slight giddiness and lightness of the head and partial loss of power in the lower limbs. In one case the symptoms of active poisoning by cocculus have been described as including gastro-intestinal irritation, congestion of the brain, strabismus, sweating, exhaustion, and death. The absence of any spasmodic phenomena throws doubt upon the alleged nature of the attack (Stillé, *Therapeutics*, 4th ed., ii. 353). A case is reported by Sosinsky in which several ounces of whiskey impregnated with cocculus were taken by a male adult. Within an hour he became unconscious, and was seized with epileptiform convulsions. The pupils were contracted and the respiration was slow, and there was also profuse sweating, with diarrhœa.

Death occurred in 3 hours, "and was apparently due to failure of respiration and exhaustion" (*Med. News*, xliii. 485).

Medical Uses.—The resemblance between the actions of picrotoxin and of strychnine led to the use of the former in *paralysis* of the extremities and of the sphincters of the bladder and rectum, but the degree of its success does not appear to have been very great. Its virtues in curing *epilepsy* have been confidently set forth by Planat, who recognizes, as the sole exceptions to its curative power in this affection, inveterate cases, whether idiopathic or symptomatic. This physician reports no less than sixteen cases of the disease cured by a saturated tincture of cocculus, of which the primary dose was 2 drops twice a day, and on each subsequent day every dose was increased by 1 drop until 30 drops a day were given. It was then gradually reduced until the original dose was reached, when the medicine was suspended for a fortnight, after which it was renewed and intermitted alternately during 6 months. If the results above related could be relied upon, then cocculus would be a remedy for epilepsy of far higher curative power than any one before used in the same disease. This is far from being the case, for the observations of Gowers and Ramskill render it probable that picrotoxin aggravates the paroxysms in epileptic patients (*Times and Gaz.*, Apr. 1880, p. 448). Planat attributes to the medicine a striking curative power in infantile *clampsia*, in chronic *spasm of the limbs*, and in *chorea*. A case of labio-glosso-pharyngeal *paralysis* is stated to have been greatly benefited by the hypodermic injection of 1-Mgm. (Gr. $\frac{1}{64}$) doses of picrotoxin (Gubler). Much more positive are the effects of picrotoxin in controlling *night sweats*, as illustrated by Murrell (*Practitioner*, xxiii. 241; xxv. 93). He made use of a solution of 1 part in 240, as follows: Picrotoxin 8 gr.; Glacial acetic acid fl̄jiv; distilled water, to fl̄jiv. Mix and filter. Of this solution 4 minims contain $\frac{1}{60}$ gr. of picrotoxin, which is the average dose. From 1 to 4 teaspoonfuls of the solution seldom failed to diminish, and then arrest, the sweating, without leaving the skin dry. It did not disagree with the stomach. Picrotoxin may also be given in pills, each containing one-sixteenth of a grain. Cocculus indicus is employed in decoction or in ointment to destroy *lice*, and in the latter form to cure *ringworm of the scalp*. The skin should in this disease be thoroughly cleansed with soap and water before applying the ointment. *Porriigo* has been cured by an ointment made with 10 grains (Gm. 0.60) of picrotoxin to an ounce of lard. Cocculus indicus is said to prevent the secondary fermentation of liquors, and for this purpose it is sometimes added to malt liquors at the risk of poisoning those who drink them. The average hypodermic dose of picrotoxin is 1 Mgm. or $\frac{1}{64}$ of a troygrain.

PILOCARPINÆ HYDROCHLORAS, U. S.—HYDROCHLORATE OF PILOCARPINE.

Pilocarpinum hydrochloricum, P. G.; *Hydrochlorate de pilocarpine*, Fr.; *Pilocarpinhydrochlorid*, G.

Formula $C_{11}H_{16}N_2O_2HCl$. Molecular weight 244.4.

Preparation.—Diluted hydrochloric acid is neutralized with pilocarpine, and the solution concentrated and set aside over sulphuric acid to crystallize.

Properties.—This salt forms long colorless needles or is obtained in small white needle-shaped or scaly crystals. It is inodorous, and has a slightly bitter taste and a neutral reaction to test-paper. It is deliquescent on exposure, and dissolves, according to Schuchardt (1881), in $1\frac{1}{2}$ parts of water at 15° and at 100° C. (59° and 212° F.) in 7 parts of alcohol at 15° C. (59° F.), and in about $\frac{2}{3}$ part of boiling alcohol. According to Poehl, it is insoluble or nearly so in ether, chloroform, benzol, and carbon bisulphide, but, according to Gerrard (1876), chloroform dissolves the salt. This melts on the application of heat, and at a higher heat is decomposed without leaving any fixed residue. The aqueous solution remains clear for many weeks, and yields with silver nitrate a white curdy precipitate insoluble in nitric acid, but soluble in ammonia. Only concentrated solutions are precipitated by soda (whitish cloudiness) or by platinic chloride (yellowish, crystalline), but diluted aqueous solutions are precipitated by mercuric chloride (white, soluble in hydrochloric acid), iodine (brown-red, crystallizable), phosphomolybdic acid (yellow, curdy), and other group reagents for alkaloids. Pure sulphuric acid dissolves the salt nearly colorless; in the presence of a little potassium bichromate the solution is at first brownish-green, but soon changes to a lasting bright-green color (Poehl, 1879). Fuming nitric acid dissolves the salt with a pale greenish color (P. G.); it gives with nitric acid sp. gr. 1.400 a faintly greenish-violet tint (U. S.).

Composition.—The formula given above is that of Harnack and Meyer, but Kingzett maintains that the correct formula of the salt is $C_{23}H_{34}N_4O_4(HCl)_2$.

Allied Salt.—PILOCARPINÆ NITRAS, Br., $C_{11}H_{16}N_2O_2.HNO_3$. White crystalline powder or needles, soluble in 8 or 9 parts of water, or freely soluble in hot alcohol.

Dose. Hydrochlorate of pilocarpine may be administered by the mouth in doses of $\frac{1}{2}$ to $\frac{3}{4}$ gr. (Gm. 0.03–0.05), and hypodermically $\frac{1}{4}$ gr. (Gm. 0.02) may be given. (See PILOCARPUS.)

PILOCARPUS, U. S.—PILOCARPUS.

Jaborandi, Br., F. Cod.; *Folia jaborandi*, P. G.—*Jaborandi*, Pernambuco *jaborandi*.

The leaflets of *Pilocarpus pennatifolius*, Lemaire, s. *P. pinnatus*, Martius. Bentley and Trimen, *Med. Plants*, 48.

Nat. Ord.—Rutaceæ, Xanthoxyleæ.

Origin.—*Jaborandi* is a kind of generic name used in South America for several plants possessing diaphoretic properties. The *Pilocarpus jaborandi* is a shrub growing in Brazil in the neighborhood of Pernambuco, perhaps also in the southern provinces of that empire. E. M. Holmes (1875) determined the origin of *jaborandi*. There appear to be several more or less distinct forms of *Pilocarpus* in Brazil, which are regarded as distinct species by some botanists, while others regard them as mere varieties. Of these may be mentioned—*Pil. Selloanus*, Engler, *Pil. heterophyllus*, A. Gray, and *Pil. pauciflorus*, St. Hilaire. From the anatomical structure of the leaves constituting the drug Poehl (1879) regards it to be obtained from an undescribed species, *Pil. officinalis*, Poehl.

Description.—The leaves are imparipinnate, and are composed of four to ten short-stalked leaflets with an unequal base, and a terminal one which has a longer stalk and is more tapering and nearly equal at base. The leaflets are about 4 inches (10 Cm.) long,

oval or ovate-oblong, entire and slightly revolute at the margin, rather rounded below and obtuse and usually emarginate above. They are of a coriaceous texture, green and shining above, and on the under side paler and smooth or somewhat hairy, and with a prominent midrib; the veins branch from the midrib at nearly right angles, and anastomose near the margin, forming on each side one or two distinct wavy lines. The entire blade is marked with numerous pellucid glands. The leaves are nearly inodorous, but when bruised exhale a slight aromatic odor; the taste is herbaceous, afterward aromatic, warm, and somewhat bitter.

Constituents.—Byasson (1875) obtained from *jaborandi* leaves a volatile oil, and a volatile alkaloid which he named *jaborandine*. But both Gerrard and Hardy (1875) showed that the alkaloid is not volatile, and named it *pilocarpine*. It is obtained from the aqueous solution of the alcoholic extract by adding an alkali, agitating with chloroform, and extracting it from the latter by agitation with water acidulated by hydrochloric acid. It is best purified by crystallizing the nitrate from boiling alcohol, which, according to Schuchardt, dissolves 2.5 per cent. of the salt, while at 15° C. (59° F.) only .77 per cent. remains in solution. The alkaloid is uncrySTALLIZABLE, but A. W. Gerrard (1875) crystallized from alcohol a number of its salts, of which the sulphate and acetate are very deliquescent; the latter is also soluble in ether, chloroform, and benzol, in which the nitrate and phosphate are insoluble, while the chlorhydrate and bromhydrate dissolve besides in water and alcohol, also in chloroform. Kingzett (1876) gives to the alkaloid the formula $C_{23}H_{34}N_4O_4$, and states that on distillation with caustic potassa it yields trimethylamine, and that *jaborandi* contains only one alkaloid. These observations have been corroborated by Gerrard (1880). But Harnack and Meyer (1880) give to pilocarpine the formula $C_{11}H_{16}N_2O_2$. Chastaing (1881) found the same composition, and states that on treating the alkaloid with a large excess of fuming nitric acid nitrate of *jaborandine*, $C_{10}H_{12}N_2O_3.HNO_3$, is obtained,

FIG. 213.

Pilocarpus pennatifolius, Lemaire:
leaflet, natural size.

taing (1881) found the same composition, and states that on treating the alkaloid with a large excess of fuming nitric acid nitrate of *jaborandine*, $C_{10}H_{12}N_2O_3.HNO_3$, is obtained,

together with traces of another alkaloid, probably jaborine. Poehl (1879) agrees with Kingzett's formula: he also found but one alkaloid, but on distilling this with caustic soda obtained *coniine*. The latter alkaloid was also obtained by Harnack and Meyer, but only from impure pilocarpine, and they believe it to be a decomposition-product of a second alkaloid, *jaborine*, which could not be prepared in the pure state, and is probably produced by the alteration of pilocarpine; it is yellow, amorphous, more soluble in ether and less in water than pilocarpine, and resembles atropine in its action.

Hardy (1876) obtained from the leaves 0.56 per cent. volatile oil, consisting of *pilocarpene*, $C_{10}H_{16}$ (sp. gr. .85; boiling-point 178° C.), and two hydrocarbons of higher boiling-points.

Other Jaborandis.—Peckolt (1875) enumerated the following Brazilian drugs which are known in some of the provinces as jaborandi, and belong either to the natural order of Piperaceæ or to that of Rutaceæ (Xanthoxylaceæ):

1. *Serronia* (Piper, *Vellozo*, Ottonia, *Kunth*) Jaborandi, *Guillemin*; 2. *Piper reticulatum*, *Linneé*; 3. *P. nodulosum*, *Link*; 4. *Artanthe Mollicoma*, *Miquel*; 5. *Aubletia* (*Monniera*, *Linneé*) trifolia, *Richard*; and 6. *Xanthoxylum elegans*, *Engler*. *Herpestes gratioides*, *Kunth* (nat. ord. Scrophulariaceæ), is also stated to yield a jaborandi; and to these must probably be added *Piper citrifolium*, *Lamarek*, and perhaps other species. (See paper by Dr. F. V. Greene in *Phil. Med. Times*, 1877, p. 537.)

Piper Jaborandi, *Vellozo*, is, according to Peckolt, the true jaborandi of Brazil, and, according to Parodi (1875), the true *yaguarandi* of Paraguay. The latter isolated from it a volatile oil of an acrid and biting taste and a crystalline alkaloid, *jaborandine*, $C_{10}H_{12}N_2O_3$, which is slightly soluble in ether and has but a weak affinity for acids.

Off. Prep.—Extractum pilocarpi fluid., *U. S.*, and Extr. jaborandi, *Br.* (See p. 654.)

INFUSUM JABORANDI, *Br.*—Jaborandi $\frac{1}{2}$ ounce, boiling water 10 fluidounces; infuse for half an hour and strain.

TINCTURA JABORANDI, *Br.*, *F. Cod.*—Jaborandi 5 ounces, proof spirit 20 fluidounces (*Br.*). Jaborandi 100 Gm.; alcohol (sp. gr. .912) 500 Gm. (*F. Cod.*).

Substitutions.—The leaves of one or more species of *Piper* have occasionally been in the market and sold as jaborandi; they are thin or subcoriaceous, ovate, acuminate, and so finely glandular that on being held up to the light and examined with the naked eye they do not appear to be pellucid punctate.

We have seen the leaves of *Laurus nobilis*, *Linneé*, offered as jaborandi; they are easily distinguished by the characters described on page 874.

Physiological Action.—*On Animals:* Jaborandi and its preparations given to guinea-pigs and dogs do not occasion sweating, but in the latter animals induce salivation and diarrhœa, and when they are sacrificed extreme congestion of the gastro-intestinal mucous membrane is found, and sometimes hæmorrhage. In horses pilocarpine injected hypodermically caused profuse sweating, commencing near the point of puncture, as well as salivation. Injected into the veins, it causes primarily an increased, followed by a diminished, blood-pressure and a fuller volume of the pulse-wave. Luchsinger, on administering hypodermically to cats $\frac{1}{4}$ grain (Gm. 0.01) of muriate of pilocarpine, found that in 2 minutes salivation began, and very soon afterward sweating of the paws, which lasted for several hours. Vulpian observed that by such administration the secretions of the liver and pancreas were increased. Thus, pilocarpine appears to be the opposite of atropine in its action.

On Man: When a jaborandi-leaf is chewed it causes an acrid sensation in the fauces, and the powder by prolonged contact with the skin irritates it. In doses of from 30 to 90 grains (Gm. 2–6) infused in boiling water, the water and grounds being swallowed together, it produces within ten or fifteen minutes its characteristic effects. Very similar, if not identical, effects are produced by the hypodermic injection of muriate of pilocarpine in the dose of $\frac{1}{4}$ to $\frac{1}{2}$ gr. (Gm. 0.01–0.02). Pilocarpine acts more promptly than jaborandi, especially when used hypodermically. In the dose just indicated it produces, in the course of two or three minutes, a flushing of the face and breast, and in from three to six minutes drops of sweat appear upon the forehead and moisture is felt in the axillæ and groins, and then upon the trunk and limbs. In a case of glaucoma the patient by mistake received a hypodermic injection of 6 grains instead of $\frac{1}{4}$ gr. of pilocarpine. Hardly had the needle been withdrawn before the saliva began to dribble from the patient's mouth (*Med. Record*, xx, 599). The amount and duration of the sweating are increased by the patient's remaining covered in bed, and also depend in part upon individual peculiarities. The secretion of tears and of nasal and bronchial mucus is commonly augmented. These abundant losses of liquid necessarily reduce the patient's weight, often to the extent of from 2 to 6 pounds, and occasionally as much as 8 pounds. It sometimes also increases the bronchial secretion, or causes diarrhœa, or produces swelling of

the submaxillary glands. During the sweating the temperature is apt to fall about 1° F., the pulse grows fuller and tenser, and its rate is at the same time increased, sometimes by as much as 40 or 50 beats a minute. The face becomes flushed at first, but grows pale when the perspiration is most profuse. These phenomena are attributed to the action of the medicine upon the heart and arteries, whereby their walls are dilated and their capacity increased. Meanwhile, at the time when the sweat breaks out the patient feels his mouth begin to water, and the flow of saliva is so rapid, and often so copious, that he is unable to speak. During the hour and a half, on an average, that the secretion lasts, it may amount to 1 or 2 pints. The saliva is usually ropy. During these operations some drowsiness is apt to occur, which seems to be owing to exhaustion rather than to any narcotic virtue in the drug, and in some cases the sight is so clouded that only very near objects can be distinctly seen. In rare instances sweating fails to occur, and salivation is much less usual than sweating. The fall of temperature noticed above seems usually to be due to the diaphoresis, but it sometimes is observed independently of the latter symptom. Vomiting is an ordinary effect caused in part by the irritation of the medicine when given by the stomach, but in part also by the large amount of saliva swallowed. Hiccough is not uncommon. It is noteworthy that the usual promoters of diaphoresis are quite unnecessary when this medicine has been given. It is the only direct and essential diaphoretic in the materia medica. During the sweating and salivation produced by jaborandi the quantity of urine excreted is diminished, and it is voided with pain. Nearly all observers agree that it contains less than the normal proportion of urea, but some have found it to be increased. Urea is, however, largely eliminated with the saliva and the sweat. Sphygmographic observations denote a dilatation and diminished tension of the whole vascular system during the action of jaborandi, and in experiments upon frogs the heart becomes gradually distended, and finally ceases to beat in diastole. The imperfect vision sometimes produced by the internal use of this drug has already been alluded to. It is attributed to a defect of accommodation. When the extract of jaborandi or pilocarpine dissolved in glycerin is introduced into the eye, it in most cases contracts the pupil, but when taken internally it produces this effect much less uniformly, if at all. Instead of diminishing the secretion of milk, as might reasonably be expected from its causing such profuse discharges elsewhere, it appears to be a true galactagogue. It is said to exhibit this virtue even when directly applied to the mammae (*Practitioner*, xvii. 443). Children are but little affected by doses which would produce the full operation of the medicine in adults.

A remarkable effect of pilocarpine given hypodermically is described by Strauss, who states that it produces a local sudation confined to the neighborhood of the puncture, provided that the dose be duly proportioned—not exceeding, *e. g.*, $\frac{1}{32}$ to $\frac{1}{16}$ grain. He also found that when copious sweating was produced by one or two milligrams ($\frac{1}{64}$ to $\frac{1}{32}$ grain) of pilocarpine, a very minute injection, such as a hundredth, or even a thousandth, of a grain of atropine will arrest the secretion within a greater or less area (*Bull. de thérap.*, xviii. 478). The experiments of Van der Mey (*Archives gén.*, 7ème sér., iv. 621) of Müller (*Practitioner*, xxvi. 55), of Hyernaux and others (*Monthly Abst.*, Nov. 1879, p. 483) render it certain that pilocarpine is useless if not mischievous as an oxytocic. The small advantage derived from its dilating the os uteri is greatly outweighed by the prostration and annoyance it occasions.

There can be no doubt that these medicines, especially muriate of pilocarpine, sometimes occasion distressing and even alarming symptoms, such as nausea, vomiting, diarrhœa, tenesmus, collapse, tremor, indistinct vision, sighing respiration, rapid pulse, palpitation of the heart, and vertigo, for which the appropriate remedy is a hypodermic injection of atropine; the inhalation of nitrite of amyl has also been used for the same purpose.

Jaborandi resembles atropine in quickening the pulse and flushing the face, and in acting more powerfully upon adults than upon children; but it is antagonistic to atropine in its action upon the salivary, sudoral, and mammary secretions, upon the pupils also, and the minute arteries. Moreover, the tendency of belladonna to excite delirium contrasts with that of jaborandi to cause prostration and drowsiness, and the sweats and salivation produced by the latter are checked by the hypodermic injection of atropine. The dryness of the mouth and skin which this alkaloid or belladonna occasions is relieved by the administration of jaborandi or pilocarpine. The mammary secretion is diminished by the one and increased by the other. In this connection it may be mentioned that in experiments upon frogs the dilatation of the heart produced by the one agent has been overcome by the operation of the other. Nevertheless, it has happened in cases of poisoning

by belladonna or its alkaloid that no mitigation of the symptoms followed the administration of jaborandi or of pilocarpine.

Pilocarpine or its muriate, when injected hypodermically in the dose of about $\frac{1}{4}$ grain, gives rise to effects which in their nature are almost identical with those of jaborandi taken internally, but they are more promptly produced, as well as more certainly, and are more lasting. Sweating especially, which sometimes fails to occur under the operation of jaborandi, is invariably excited by pilocarpine, which is also, when thus administered, less apt to cause vomiting, probably because it does not irritate the stomach.

Medical Uses.—The utility of jaborandi in medicine is chiefly shown by its power of lessening the amount of liquid in the system. Hence it is often of service in removing effusions due to cardiac or renal obstruction, and even to inflammation. The last effect has been illustrated in some cases of chronic as well as acute *pleurisy*, probably, however, with serous rather than purulent effusion. The relief afforded by the medicine is sometimes wonderfully prompt, and is all the more so if the patient refuses to yield to his thirst and abstains, as far as possible, from using liquids. In children the relief is more apt to be afforded by profuse salivation than by sweating. In *hydrothorax* the benefit is even more speedy and complete, although its duration must depend upon the cardiac or renal disease during which it occurred. When *dropsy* arises in connection with desquamative *tubular nephritis* (especially scarlatinous), or even with *interstitial nephritis*, the medicine is very efficient; in the former disease often leading to a cure, and in the latter to a prolongation of life. But it can be of no service unless its sialagogue or its diaphoretic action is fully developed. A danger, however, which, perhaps, attends this treatment of acute renal dropsy is that the discharge of water by the skin diminishes the excretion of the kidneys, and if carried too far may cause them to become obstructed and uræmic symptoms to arise. In regard to the dropsy of pregnancy and the usually associated *puerperal albuminuria* and *convulsions* the efficacy of the medicine does not yet appear to be determined. In some cases its administration has been followed by its physiological effects and the dissipation of threatening symptoms; but some physicians (Bidder, Fordyce Barker) regard its utility as more than doubtful, and the latter states that after puerperal convulsions its depressing influence, which is continuous and exhausting, prevents sleep and the repose of the nervous system, and thus renders it in these cases a dangerous remedy. On the whole, however, there is no speedier relief to be obtained than by this medicine, which undoubtedly acts precisely as another and now neglected remedy did under similar circumstances. Venesection is the remedy referred to. Serous evacuation is almost as prompt in giving relief, and does not waste the vital and nutritive constituents of the blood. The special indication for jaborandi is the necessity of prompt action; and it is perhaps wiser not to persist in prescribing it after safety has been secured, lest perchance the case may become embarrassed by secretion into the air passages, and also because the prolonged diaphoresis may aggravate the renal obstruction. In *dropsy* caused by *disease of the heart* it is a temporary palliative which may appropriately be used from time to time during a treatment by digitalis, etc. Indeed, it simply serves as a substitute for the ancient practice of purging, or sweating by heat, etc., and may be used alternately with them. Its action in lessening the contractile power of the heart and arteries, and retaining them in diastole, should be borne in mind, since it tends to favor the accumulation of blood in them and to obstruct instead of relieving the circulation and respiration. In all cases in which the rhythm of the heart is disordered by valvular or muscular degeneration this medicine should be cautiously used, lest during the prostration it cause the action of the heart to be suspended. Used in certain cases of pulmonary *emphysema*, it has embarrassed respiration and threatened to produce asphyxia. But when dropsy of whatever form (*hydrothorax*, *ascites*, *anasarca*) due to Bright's disease is associated, not with obstructive lesions of the heart, but with hypertrophy of the left ventricle, the relief obtained from jaborandi is immediate and striking. Yet the rule must not be too absolutely followed. In cases of obstructive diseases of the heart from valvular or muscular degeneration, with *emphysema*, and even disease of the arteries, the action of pilocarpine may sometimes be so adjusted as to afford relief without embarrassing the circulation. In a case of *œdema of the larynx* the hypodermic use of pilocarpine seems to have saved life (*Bull. et Mém. Soc. de thérap.*, 1881, p. 146). In 1880 and for several subsequent years marvellous success was announced from the use of pilocarpine in *diphtheria*, on the ground, apparently, of the salivation induced by it causing the separation of the false membranes. As usual, the "rational" anticipation resulted in disappointment, and it was found that the medicine added to the disease a new element of weakness, and therefore of danger. A caution has been given to beware of the possible

uræmic symptoms that may follow the diminished urination, but as urea is eliminated by the saliva and sweat the advice is perhaps not very important. The utility of pilocarpine in all forms of dropsy is precisely like that which has long been derived from hot-air and steam-baths and other powerful diaphoretics, but is greater, inasmuch as it excites profuse salivation as well as sweating. It must be borne in mind also that some clinical observers have found it injurious by causing distressing nausea and vomiting, and so exhausting the strength that its repeated use was not tolerated.

Pilocarpine is alleged by some practitioners to bring on labor in pregnancy at term, and to hasten and facilitate it when once begun. Its influence in these respects is not, however, determined. According to Galezowski, pilocarpine equals eserine in its power of *contracting the pupil*, and has the advantage of not irritating the conjunctiva. He prefers a solution of 20 Gm. of the nitrate in 10 Gm. of cherry-laurel water, or of 10 Gm. of the sulphate in 6 Gm. of the same solvent. Dr. H. W. Williams has confirmed this judgment, adding that it produces less supraorbital pain than the eserine sulphate, and less spasm of the accommodative power. It is used chiefly in cases of corneal lesions in which it is desirable to withdraw the iris from the danger of prolapsing or of adhering to the cornea. It was observed by Schmitz that the administration of muriate of pilocarpine hypodermically caused a growth of downy hair on the scalp of two men affected with *alopecia*. A like effect has been reported by André (*Bull. de thérap.*, ci. 139), and others belonging to diseases of the scalp by Pick (*Phila. Med. Times*, x. 451). A case is reported of a "change of color of the hair from light blond to nearly jet black in a patient while under treatment by pilocarpine" (Prentiss, *Phila. Med. Times*, xi. 609).

Jaborandi has been employed to diminish the discharge of urine in watery and also in saccharine *diabetes*, but it only changes the outlet of the liquid without reducing the loss. The morbid conditions producing *polyuria* are so various that the excessive flow of urine cannot in all cases be under the control of the same agent. In the present case it is doubtful whether the simple functional (?) affection, or the excessive urination that attends the first stage of interstitial Bright's disease, or chronic poisoning by lead, is most benefited by the vicarious discharge of liquid under the influence of pilocarpine. Upon "scientific principles" jaborandi should be a specific for acute articular *rheumatism*, but clinically it is so far from curing the disease that it does not even modify its symptoms or its course. In syphilitic rheumatism its sudorific action is said to have removed the nocturnal pains, and it has been efficacious in muscular rheumatism and *sciatica*. In scaly *skin diseases* it is useless. In *prurigo* it is a palliative. Some published cases render it probable that the sudorific power of pilocarpine may take the place of the sweating by means of the " decoction of the woods " which was once considered essential to the cure of constitutional *syphilis* (*Practitioner*, xxvi. 55; *St. Bart's Hosp. Reports*, xvi. 280). In *mumps* it is reported to have been curative both of the parotid swelling and of the metastatic engorgement of the testicles. In a case of unilateral *sweating* the hypodermic injection of pilocarpine is reported to have cured the affection after having at first increased it. In *asthma* with bronchitis (humid asthma) it sometimes affords surprising relief. A case of persistent *hiccup* from disease of the brain, and which had resisted various other remedies, yielded at once to the hypodermic injection of $\frac{1}{2}$ grain (Gm. 0.03) of pilocarpine. A case of reputed *hydrophobia* treated by means of pilocarpine is said to have recovered, but the Academy of Medicine of Paris did not regard the case as being accurately designated (*Bull. de thérap.*, ciii. 39). In several cases pilocarpine has served as an antidote to the poisonous effects of *atropine* and *belladonna*. Its effects appear to be prompt and decided (*Phila. Med. Times*, x. 415; *ibid.*, xi. 637; *Med. Record*, xx. 41; *Edinb. Med. Jour.*, xxviii. 1048). Hypodermic injections of nitrate of pilocarpine are said to have cured *fetid sweating* (*Bull. de thérap.*, c. 135).

Jaborandi may be administered in an infusion made with 90 grains of the medicine and 4 fluidounces (Gm. 6 in Gm. 128) of water, and taken in three or four equal portions at intervals of 10 minutes. To avoid nausea it may be given by enema. A concentrated tincture containing the virtues of 30 grains in a fluidrachm (Gm. 2 in Gm. 4) of the preparation, and a fluid extract made with 50 per cent. alcohol, a fluidrachm (Gm. 4) of which represents 60 grains (Gm. 4) of jaborandi, have both been employed. Pilocarpine or its nitrate may be prescribed by the mouth in doses of from $\frac{1}{4}$ to $\frac{3}{4}$ grain (Gm. 0.03–0.05), and hypodermically $\frac{1}{4}$ grain (Gm. 0.02) may be given. Squire recommends muriate of pilocarpine in solution as the best form to use—1 grain to 15 minims of water for hypodermic injections, 1 grain to 4 ounces of water for internal use, one-third of a grain being the largest, and one-fifteenth of a grain the smallest, dose needed.

PILULÆ.—PILLS.

Pilules, Fr.; *Pillen*, G.

Pills are medicaments which have been formed into spherical, or sometimes slightly elongated or more or less lenticular, bodies, intended to be swallowed without being previously masticated. Their weight ranges from less than 1 grain to about 5 grains (0.3 Gm.) for vegetable substances, or about 8 or 10 grains (0.5 or 0.6 Gm.) for heavy mineral compounds; if a pill exceeds this weight it is called a *bolus*. Boluses are occasionally made weighing 20 or 30 grains (1.3 or 2.0 Gm.) each, and are often of a softer consistence than pills. Very small pills coated with sugar have been called *granules*.

Excipients.—All drugs and chemicals may be worked into pills, but few only are adapted for this purpose without the addition of some other liquid or solid material, called the excipient, to impart to them the necessary plasticity. Soap, gum-resins, some resins, and several extracts do not require any addition except a few drops of water or alcohol, with which they may be triturated into plastic masses, and then serve as excellent excipients for many non-adhesive drugs. Treated in the same manner with ether, lupulin will furnish a mass suitable for pills. That the majority of extracts are unfit for the preparation of pills without the addition of an absorbent powder is explained at page 611. Absorbent powders, like powdered marshmallow, liquorice-root, bread-crumbs, etc., are likewise required for liquids, such as *fixed* and *volatile oils*, *oleoresins*, *balsams*, etc., but such mixtures, if containing more than minute quantities of the oily liquid, cannot conveniently be formed into a pill mass by the addition of mucilage or syrup. The substances named are best combined with a solid fat, like butter of cacao or expressed oil of nutmeg, or with wax in sufficient quantity to form a plastic mass; however, it is preferable in such cases to use also some absorbent powder, and for volatile oils the wax is better replaced by a resin, like mastic. The proportion in which such excipients are to be used may be stated as being, for every 5 parts of the medicine 10 parts of the two excipients, of which not less than 2 parts should be wax, resin, or solid fat. Very limpid oils require a somewhat larger proportion of the excipients, and the absorbent powder need not necessarily be inert. Powdered marshmallow-root is capable of absorbing a larger amount of liquids than most other vegetable powders, but it has the disadvantage of rendering the pill mass more or less elastic, and the pills if kept on hand for a prolonged time are apt to become mouldy. Powdered liquorice-root is nearly free from these objections, and is therefore more largely employed than the former; prepared from peeled Russian liquorice-root, it is of a light-buff color and does not materially darken most pill masses.

Ethers, *chloroform*, and similar liquids are not adapted for use in pill form, owing to their great volatility; and *tinctures*, unless added only in very small quantities, in which case they are triturated with the absorbent powder, are best reduced by evaporation to the consistence of a soft extract.

It is also advisable to avoid prescribing very *deliquescent compounds* in the form of pills unless these are immediately covered with a substance impervious to moisture; or the pill mass may be formed with a mixture of 1 part of wax and 3 parts of Canada balsam, as proposed by Dannecey (1877).

Many vegetable powders contain an amount of gum or similar principle sufficient to form, by trituration with a little *water*, *honey*, *syrup*, or *glycerin*, an adhesive mass suitable for making pills. Saline and mineral substances, as a rule, require a firmer excipient, but in the presence of a small quantity of an extract the addition of a minute proportion of glycerin will often produce a plastic mass.

It is obvious, from the foregoing, that there cannot be an excipient which would be alike serviceable for all medicinal substances, or even for all drugs capable of being reduced to powder. The choice of the excipient is very frequently left to the pharmacist, and involves a knowledge not only of the constituents of the drugs, but also of the reactions which may take place between the different ingredients in the presence of moisture. *Mucilage of acacia* or of *tragacanth* serves a good purpose if the pills are to be used in a short time, but if kept on hand they become hard and dissolve very slowly. This may be prevented by replacing about one-half or more of the water with *glycerin*. The *glycerite of starch* (see p. 739) and various combinations of it with gum-arabic, tragacanth, and sugar have been used for the same purpose. Some very soluble salts, like boro-tartrate of potassium, have been recommended as excipients, but are scarcely required. Commercial syrupy *glucose*, *mannu*, the official *pill masses*, most of the official *confections*, and

more particularly that of rose, of hip, and of senna, will render powders adhesive, and if *extracts* are not inadmissible they will be found to yield good pill masses with a comparatively large amount of powder; a rather soft extract is capable of serving as an excipient for its own weight of vegetable powder and three or four times its weight of resins and insoluble salts, and with the addition of a little syrup or honey twice the weights indicated may be incorporated.

FIG. 214.

Pill-tile, graduated.

FIG. 216.

Pill-roller.

FIG. 215.

Pill-machine.

As a rule, it will be found desirable for the physician to order some adhesive material, like extracts, together with the other ingredients of pills, but the former should not be in excessive quantities, so as not to require the addition of inert absorbent powder. When no excipient is directed, the pharmacist should select one which is simple in composition, does not increase the bulk of the mass, and is not liable to become very hard. When resinous extracts and similar materials are ordered, an excipient is not often required, but the powders may be triturated together in a warm mortar and the plastic mass rolled out into pills while still warm. The compound cathartic pills furnish an example of this kind.

Preparation.—After the mass has been uniformly mixed and properly prepared in the mortar, or for a small number of pills upon a glazed slab, it is rolled out either by means of a spatula or a flat piece of hard wood, or when the mass is tough or voluminous the flat back of the cutter of a pill-machine is used. A cylinder of uniform thickness and the desired length having been obtained, it is cut into the requisite number of pieces upon a graduated tile or by means of a pill-machine. Several sizes of the latter are usually kept in the shops for preparing pills of different sizes, and serve not only for dividing, but likewise for shaping, the pills by placing the cylindrical roll upon the cutting surface and moving the cutter forward and backward with a gradually increased pressure. Those pieces which have not become spherical or which have been cut by hand are rolled between the fingers until they are nearly globular, after which they are placed upon a smooth surface and completely rounded by means of a slight pressure of the fingers, or by rotating them under the blade of a pallet-knife or under a flat piece of hard wood similar to the pill-roller. Various implements have been constructed for giving the pills a uniform finish: they usually consist of a circular, smooth, rolling surface with a projecting margin adjustable to pills of different size.

Pill-dusting.—The pill mass, being plastic and adhesive, is apt to adhere to the slab and the fingers while being rolled out and shaped into pills. This is prevented by the use of a fine powder, which should be strictly inert unless otherwise directed by the physician. Among the most suitable powders are liquorice-root, marshmallow-root, and lycopodium. The fineness and uniformity of the latter, its slight adhesive qualities, and its tastelessness render it particularly desirable for this purpose. Powdered starch is usually too slippery, but when mixed with finely-powdered sugar and gum-arabic is sometimes preferable on account of its white color. Magnesia and magnesium carbonate should be used with due care, on account of the possible chemical effect upon the ingredients of the

pills. Powdered talc (soapstone), with or without sugar and gum-arabic, is likewise serviceable, and has the advantage of imparting a very thin opaque and tasteless coating to the pills without impairing their solubility in the stomach. When asafetida or other substances of a nauseous odor are given in the form of pill, the odor may either be entirely covered or considerably modified by the use of powdered cinnamon, aromatic powder, ginger, or a similar powder.

Pill-coating.—If the pill mass be not too soft, the amount of powder adhering to the surface of the finished pill is quite small, though generally sufficient, if quickly swallowed, to cover the taste of bitter and nauseous ingredients. More perfect coverings may

FIG. 217.

Apparatus for coating pills.

be obtained in various ways, an ordinary rather deep pill-box being used, or preferably an apparatus made of hard wood consisting of two hollow hemispheres, to one of which a short handle is attached. For *silvering* or *gilding* the pills are made firm, if possible rolled out and shaped without using any powder, and after a perfectly smooth surface has been obtained they are slightly dampened and introduced into the apparatus, together with the requisite quantity of gold- or silver-leaf; after a rapid rotary motion for a few seconds the pills will be found uniformly coated with the thin metal. Glycerin should not be used as an excipient or only in very small quantity, as it lessens the brightness of this kind of coating.

The same apparatus may likewise be employed for *sugar-coating* pills extemporaneously. To accomplish this, the pills receive first a thin coating of a thick mucilage, syrup of acacia or albumen, by rotating them upon a moistened slab or in a saucer, after which they are introduced into the apparatus with not too large a quantity of very finely-powdered sugar. The smoothness of the surface of the sugar depends altogether upon the mutual attrition of the pills, and consequently upon the absence of too large an excess of sugar and upon the rapidity of motion during the operation. A coating of *French chalk* may be applied in the same manner. Pills are now extensively coated with sugar on the large scale, hemispherical copper pans being used to which a somewhat eccentric rotary motion is given; these pans may be moderately heated either by steam or otherwise. To obtain a uniform and compact coating the powdered sugar is added gradually as required. In France sugar-coated pills are called *dragées*, and when of very small size *granules*.

The practice of sugar-coating pills was approved by the Pharmacopœia of 1870 in reference to pills which are expected to be slow in their operation, but was stated to be of doubtful propriety in regard to those intended to act quickly, as the coating retards the solution of the pill matter in the liquids of the stomach; and the same remark holds good, with at least equal force, for nearly every other kind of coating.

Pills are occasionally coated with *tolu* or *collodion*. The operation is in both cases alike, the tolu balsam, which should for this purpose be hard at the ordinary temperature, being dissolved in ether or in chloroform; the pills are rapidly rotated, with the liquid gradually added, a flat dish being used, and afterward exposed upon a tile, and occasionally stirred until the coating is dry.

For coating pills with gelatin a different manipulation from those described is required. A solution of pure gelatin in one-half or one-third its weight of water is made, and the solution kept at a temperature just high enough to keep it liquid. The pill, fastened upon the end of a pin, is dipped into the liquid, quickly withdrawn, and, after some rotary motions to promote the uniform diffusion of the gelatin solution and its superficial hardening, the pins are fixed in a tray, where the coating is allowed to become sufficiently firm, when a second, and sometimes a third, coat is applied in the same manner. If many pills are to be thus coated, a number of pins may be fastened to a flat cork or piece of wood, and an equal number of pills dipped together. Various serviceable apparatus have been constructed to facilitate this operation. The coating of gelatin may be applied to pills while still plastic, but they should be sufficiently firm not to lose their shape while temporarily exposed to a somewhat elevated temperature. Most bitter principles being soluble in aqueous liquids, the taste of the pill mass will to some extent be communicated to the first layer of gelatin. After a sufficiently thick coating of gelatin has been applied, the pills are withdrawn

FIG. 218.

Tray with gelatin-coated pills.

after heating the pins in the flame of an alcohol or gas lamp, whereby the adjacent gelatin is melted and the orifice closed. Instead of operating in the manner described, Deschamps proposed to roll the pills in a little of the gelatin solution, previously mixed with a small quantity of alcohol, and to dry them afterward in a tray made of sheet iron or covered with oiled paper.

Compressed Pills.—These pills, which have been recently introduced, are usually lenticular in shape, and are made without

any excipient, simply by subjecting the powdered material to pressure, the process being essentially that which was patented in England in 1843. Prof. Remington (1876) constructed an apparatus which is made of cast steel, the mould being on a rod which fits in a movable cylinder into which the weighed material is introduced; the compression is effected by striking the rod with a wooden mallet a quick blow. A more uniform pressure is obtained by acting with a lever upon the compressing rod, the compressed material being then less liable to break. Powders which are readily soluble in water without being deliquescent appear to be best adapted for this kind of pills.

Preservation.—Uncoated pills are best preserved in lycopodium or other powder, and in a vessel which does not prevent the change

FIG. 219.

Apparatus for making compressed pills.

of air. Moist pills kept in well-closed vessels are apt to become mouldy.

It should be mentioned that the British Pharmacopœia directs only *pill masses*, leaving the final division to be specially ordered by the physician. The U. S. Pharmacopœia, on the other hand, besides recognizing three pill masses (see page 960), directs *pills* of a certain weight; for convenience of dispensing, however, the mass of some of these is sometimes kept on hand undivided.

PILULÆ ALOES, U. S.—PILLS OF ALOES.

Pilula aloes Socotrinæ, Br.—*Pilules d'aloès et de savon*, Fr.; *Aloepillen*, G.

Preparation.—Purified Aloes, in fine powder, 200 grains (13 Gm.); Soap, in fine powder, 200 grains (13 Gm.); to make 100 pills. Beat them together with water, so as to form a mass, and divide it into 100 pills.—U. S. For 12 pills use aloes and soap, of each 24 grains (1.56 Gm.).

The formula of the French Codex is identical with this, except that Cape aloes is used, and that 100 pills contain 10 Gm. of each of the ingredients.

Take of Socotrine aloes, in powder, 2 ounces; hard soap, in powder, 1 ounce; volatile oil of nutmeg 1 fluidrachm; confection of roses 1 ounce. Beat all together until thoroughly mixed.—Br.

PILULA ALOES BARBADENSIS, Br., is made in precisely the same manner, except that Barbadoes aloes is substituted for Socotrine aloes, and oil of caraway for oil of nutmeg, both in the same proportion as in the preceding formula.

PILULÆ ALOETICÆ, *Pilules d'aloès*, F. Cod. Cape aloes 154 grains (10 Gm.); confection of rose 77 grains (5 Gm.); make 100 pills.

Medical Action and Uses.—The soap in this pill serves to divide the aloes and render it more soluble, whereby, it is thought, the tendency of the medicine to irritate the rectum is diminished. In the British pill the oil of nutmeg is intended to lessen the tendency of the medicine to gripe. Pill of aloes is convenient as a laxative in habitual constipation, and may be taken at bedtime or after dinner. A single pill repeated daily forms the ordinary dose. It may be used as a purgative in the dose of five or more pills, but is less suited for this purpose than other aloetic preparations.

The *Pilula aloes Barbadoensis*, Br., is nearly identical as a purgative with that of the United States Pharmacopœia, but the oil of caraway it contains gives it the advantage. *Dose*, from 5 to 10 grains (Gm. 0.30–0.60).

The only difference between *Pilula aloes Socotrinæ*, Br., and that made with Barbadoes aloes, besides the source of the aloes itself, is that the former contains oil of nutmeg and the latter oil of caraway. It would seem more convenient, as well as reasonable, that the

one or the other oil should be added, as it may be according to the United States Pharmacopœia, according to the nature of the case. The dose of the Socotrine aloes pill is from 5 to 10 grains (Gm. 0.30–0.60), or two or three pills.

PILULÆ ALOES ET ASAFETIDÆ, U. S., Br.—PILLS OF ALOES AND ASAFETIDA.

Pilules d'aloès et aséfétide, Fr. ; *Aloe- und Asafetida-Pillen*, G.

Preparation.—Purified Aloes, in fine powder, 400 grains (26 Gm.) ; Asafetida 400 grains (26 Gm.) ; Soap, in fine powder, 400 grains (26 Gm.) ; to make 300 pills. Beat them together with water so as to form a mass, and divide it into 300 pills.—*U. S.* For 12 pills use aloes, asafetida, and soap, of each 16 grains (1.04 Gm.).

Take of Socotrine aloes, in powder, asafetida, hard soap, in powder, confection of roses, each 1 ounce. Beat all together until thoroughly mixed.—*Br.*

Medical Action and Uses.—These pills may take the place of the simple aloetic pill in cases of constipation attended with flatulence, and especially in nervous or hysterical persons. *Dose*, from two to five pills.

PILULÆ ALOES ET FERRI, U. S., Br.—PILLS OF ALOES AND IRON.

Pilulæ aloeticæ ferratæ, s. *Pilulæ Italicæ nigræ*, P. G., F. Cod.—*Pilules d'aloès et de fer*, Fr. ; *Aloe- und Eisenpillen*, *Italienische Pillen*, G.

Preparation.—Purified Aloes, in fine powder, 100 grains (6.50 Gm.) ; Dried Sulphate of Iron 100 grains (6.50 Gm.) ; Aromatic Powder 100 grains (6.50 Gm.) ; Confection of Rose: to make 100 pills. Beat the powders together with confection of rose so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use aloes, exsiccated sulphate of iron, and aromatic powder, of each 12 grains (0.78 Gm.).

Take of sulphate of iron $1\frac{1}{2}$ ounces ; Barbadoes aloes, in powder, 2 ounces ; compound powder of cinnamon 3 ounces ; confection of roses 4 ounces. Reduce the sulphate of iron to powder, rub it with the aloes and compound powder of cinnamon, and, adding the confection, make the whole into a uniform mass.—*Br.*

Exsiccated sulphate of iron and powdered aloes equal parts ; mix, form a mass with alcohol, and divide into pills each weighing 0.10 Gm. Moisten the pills with tincture of aloes to make the surface black and glossy.—*P. G.*

Medical Action and Uses.—This is an old and efficient combination used in the treatment of *amenorrhœa* associated with anæmia and constipation. Like other analogous compounds, it should be used habitually in moderate doses, and in larger ones at the menstrual epochs. *Dose* from 5 to 10 grains (Gm. 0.30–0.60), or two or three pills.

PILULÆ ALOES ET MASTICHES, U. S.—PILLS OF ALOES AND MASTIC.

Lady Webster's dinner pills, E. ; *Pilules d'aloès et de mastic*, Fr. ; *Aloe- und Mastix-Pillen*, G.

Preparation.—Purified Aloes, in fine powder, 200 grains (13 Gm.) ; Mastic, in fine powder, 50 grains (3.25 Gm.) ; Red Rose, in fine powder, 50 grains (3.25 Gm.) ; to make 100 pills. Beat them together with water so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use aloes 24 grains (1.56 Gm.), mastic and red rose, of each 6 grains (0.39 Gm.).

Medical Action and Uses.—The association of mastic with aloes in a purgative pill can hardly have any other effect than to retard the solution of the latter, and thereby cause it to act upon the large rather than upon the small intestine. These pills are used to quicken defecation, and are generally taken with or immediately before or after the principal meal. Hence they have been called *Pil. ante cibum*, *Pilules des gourmands*, etc. Under the latter title, however, pills are used containing extract of cinchona and absinth, as well as aloes. Each pill contains about 2 grains of aloes.

PILULÆ ALOES ET MYRRHÆ, U. S., Br.—PILLS OF ALOES AND MYRRH.

Rufus's pills, E. ; *Pilules d'aloès et myrrhe*, *Pilules de Rufus*, Fr. ; *Rufus'sche Pillen*, G.

Preparation.—Purified Aloes, in fine powder, 200 grains (13 Gm.) ; Myrrh, in fine powder, 100 grains (6.50 Gm.) ; Aromatic Powder 50 grains (3.25 Gm.) ; Syrup a sufficient quantity ; to make 100 pills. Beat them together so as to form a mass, and divide

it into 100 pills.—*U. S.* For 12 pills use aloes 24 grains (1.56 Gm.), myrrh 12 grains (0.78 Gm.), and aromatic powder 6 grains (0.39 Gm.).

Triturate together Socotrine aloes 2 ounces, myrrh 1 oz., dried saffron $\frac{1}{2}$ ounce; then add treacle 1 ounce and sufficient glycerin, and beat them together into a uniform mass.—*Br.*

Medical Action and Uses.—The proportion of myrrh in this compound is too small to exert much influence, but, owing to its supposed action upon the uterine system, it is believed to increase the virtue of the aloes in the treatment of *amenorrhœa*, *uterine catarrh*, etc. The still smaller proportion of saffron can scarcely add much to its virtues. As a purgative, from three to six pills may be given, or from 10 to 20 grains (Gm. 0.60–1.30) of the mass in a bolus. As a laxative, taken at bedtime for a week or more, one or two pills will generally suffice, and will be found the most efficient mode of administration in the uterine disorders referred to.

PILULÆ ANTIMONII COMPOSITÆ, *U. S.*—COMPOUND PILLS OF ANTIMONY.

Pilula hydrargyri subchloridi composita, *Br.*; *Pil. calomelanos composita*.—*Compound pills of subchloride of mercury*, *Plummer's pills*, *E.*; *Pilules altérantes composées*, *P. anti-dartreuses*, *P. de Plummer*, *Fr.*; *Plummer'sche Pillen*, *G.*

Preparation.—Sulphurated Antimony 50 grains (3.25 Gm.); Mild Chloride of Mercury 50 grains (3.25 Gm.); Guaiac. in fine powder, 100 grains (6.50 Gm.); Mucilage of Tragacanth a sufficient quantity; to make 100 pills. Mix the powders, beat them together with mucilage of tragacanth so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use sulphurated antimony and calomel, each 6 grains (0.39 Gm.). guaiac-resin 12 grains (0.78 Gm.).

Take of subchloride of mercury, sulphurated antimony, each 1 ounce; guaiacum resin. in powder, 2 ounces; castor oil 1 fluidounce or a sufficiency. Triturate the subchloride of mercury with the antimony, then add the guaiacum resin and castor oil, and beat the whole into a uniform mass.—*Br.*

Medical Action and Uses.—Plummer's pills—or compound calomel pills, as they might properly be called—probably owe their virtues to the mercury they contain, since various other mercurial preparations are equally efficacious in the diseases for the cure of which these pills are in greatest repute—viz. *chronic rheumatism* and *diseases of the skin*, so far as they are due to a syphilitic taint—and since the proportion of guaiac they contain can have no efficiency. The *dose* is one or two pills twice a day.

PILULÆ ASAFETIDÆ, *U. S.*—PILLS OF ASAFETIDA.

Pilule d'aséfétide, *Fr.*; *Asafetida-Pillen*, *G.*

Preparation.—Asafetida 300 grains (19.50 Gm.); Soap, in fine powder, 100 grains (6.50 Gm.); to make 100 pills. Beat them together with water so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use asafetida 36 grains (2.34 Gm.) and soap 12 grains (0.78 Gm.).

Medical Action and Uses.—These pills, especially when sugar-coated, are a convenient form for the administration of asafetida, of which each one contains 3 grains. *Dose*, from one to three pills.

PILULA CAMBOGIÆ COMPOSITA, *Br.*—COMPOUND PILL OF GAMBOGE.

Preparation.—Take of Gamboge, in powder, Barbadoes Aloes, in powder, Compound Powder of Cinnamon, each 1 ounce; Hard Soap, in powder, 2 ounces; Syrup a sufficiency. Mix the powders together, add the syrup, and beat the whole into a uniform mass.

Medical Action and Uses.—As an efficient purgative in constipation and in congested states of the portal circulation this pill may be recommended. *Dose*, from 5 to 10 grains (Gm. 0.30–0.60).

PILULÆ CATHARTICÆ COMPOSITÆ, *U. S.*—COMPOUND CATHARTIC PILLS.

Antibilious pills, *E.*; *Pilules cathartiques composées*, *Fr.*; *Abführpillen*, *G.*

Preparation.—Compound Extract of Colocynth 130 grains (8.40 Gm.); Abstract of Jalap 100 grains (6.50 Gm.); Mild Chloride of Mercury 100 grains (6.50 Gm.); Gam-

boge, in fine powder, 25 grains (1.62 Gm.); to make 100 pills. Mix the powders intimately; then with water form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use compound extract of colocynth 15.6 grains (1.008 Gm.); abstract of jalap and calomel, of each 12 grains (0.78 Gm.); gamboge 3 grains (0.195 Gm.).

In making this pill mass it is advisable to use a warm mortar and add very little water; while still warm it may be formed into pills which will better retain their shape than if made with more water at the ordinary temperature. The composition of these pills is almost exactly the same as in the previous Pharmacopœia, the abstract of jalap being of about the same strength as the extract which was formerly used (see page 7.)

Medical Action and Uses.—Whether or not the calomel in these pills acts upon the liver, as was once fully believed, there can be no question that in all cases requiring thorough purgation, in which the *gastric digestion* is *disordered*, the liver tumid and tender, the skin and the conjunctiva muddy, and the urine dark and sedimentary, these symptoms are promptly relieved by a full purgative dose of them. Hence, they are much used in malarial localities at seasons when periodical diseases prevail, and in other places for the relief of similar symptoms produced by the habit of eating excessively of animal food and using alcohol beyond the needs of the economy. There is much reason for believing that the compound cathartic pill operates as a purgative upon the entire intestinal tract.

The *dose* of this preparation as a laxative is about 3 grains (Gm. 0.20), or one pill; as an active cathartic, about three pills. It is not adapted for habitual use, on account of its tendency to produce salivation when often repeated.

PILULA COLOCYNTHIDIS COMPOSITA, *Br.*—COMPOUND PILL OF COLOCYNTH.

Pilules de coloquinte composées, Pil. cochés mineures, Fr.; Coloquinten-Pillen, G.

Preparation.—Take of Powdered Colocynth-Pulp 1 ounce; Barbadoes Aloes 2 ounces; Resin of Scammony 2 ounces; Sulphate of Potassium $\frac{1}{4}$ ounce; Oil of Cloves 2 fluidrachms; Distilled Water a sufficiency. Mix the powders, add the oil of cloves, and beat into a mass with the aid of the water.—*Br.*

The formula of the French Codex directs colocynth, Barbadoes aloes, and scammony, of each 10 Gm., honey 30 Gm., oil of cloves 0.05 Gm., to be divided into 200 pills, which are to be coated with silver.

Medical Action and Uses.—This pill is appropriate in the same cases as the compound pill of gamboge. *Dose*, from 5 to 10 grains (Gm. 0.30–0.60), or two or three pills.

PILULA COLOCYNTHIDIS ET HYOSCYAMI, *Br.*—PILL OF COLOCYNTH AND HYOSCYAMUS.

Preparation.—Take of Compound Pill of Colocynth 2 ounces; Extract of Hyoscyamus 1 ounce. Beat them into a uniform mass.—*Br.*

Medical Action and Uses.—The operation of the compound extract of colocynth in this pill is mitigated by its association with extract of hyoscyamus, but an official formula is hardly necessary for such a combination. It is better to add the narcotic extract to whatever purgative pill has a tendency to gripe, in a magistral prescription. *Dose*, from 5 to 10 grains (Gm. 0.30–0.60), or two or three pills.

PILULA CONII COMPOSITA, *Br.*—COMPOUND PILL OF HEMLOCK.

Preparation.—Take of Extract of Hemlock $2\frac{1}{2}$ ounces; Ipecacuanha $\frac{1}{2}$ ounce; Treacle a sufficiency. Mix the extract of hemlock and ipecacuanha, and add sufficient treacle to form a pill mass.

Medical Action and Uses.—This combination is intended to act as a sedative and expectorant, but the extract of conium contained in it can exert but little influence in either way. A pill of Dover's powder is much more efficient. *Dose*, from 5 to 10 grains (Gm. 0.30–0.60), or two or three pills.

PILULÆ FERRI COMPOSITÆ, *U. S.*—COMPOUND PILLS OF IRON.

Pilulæ ferri cum myrrha, F. Cod.; Pilules de Griffith, P. de fer et de myrrhe composée, Fr.; Griffith'sche Pillen, G.

Preparation.—Myrrh, in fine powder, 150 grains (9.75 Gm.); Carbonate of Sodium 75 grains (4.85 Gm.); Sulphate of Iron 75 grains (4.85 Gm.); Syrup a sufficient

quantity; to make 100 pills. Rub the myrrh first with the carbonate of sodium and afterward with the sulphate of iron, until they are thoroughly mixed; then beat them with syrup so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use myrrh 18 grains (1.17 Gm.), sodium carbonate and ferrous sulphate, of each 9 grains (0.585 Gm.).

By the reaction between the iron and sodium salts ferrous carbonate is formed, which, though an unstable compound when in contact with the air, is prevented to a considerable extent from becoming oxidized, except on the surface of the pills.

Pills of similar composition, but without myrrh, are used in Europe under the name of *Bloud's ferruginous pills*. Made according to the French Codex, twenty pills contain 3 Gm. each of exsiccated ferrous sulphate and carbonate of potassium. The ingredients may be triturated with 0.5 Gm. of powdered tragacanth, and with a little honey beaten into a good pill mass. Some formulas direct equal quantities of crystallized ferrous sulphate and potassium carbonate, and a good mass is obtained by using the granulated sulphate, beating it together with the carbonate, and adding to 16 Gm. of the mixed salts 2 Gm. of powdered tragacanth and 5 or 6 drops of syrup.

Medical Action and Uses.—These pills, each of which contains less than a grain of oxide of iron and a grain and a half of myrrh, are supposed to be peculiarly adapted to the treatment of *amenorrhœa* and of other conditions requiring the use of a reconstituent and stimulant medicine. They are intended to represent in a more convenient form the compound iron mixture, but clinical observation does not show their equality with that efficient medicine. From two to six pills may be given at a *dose*, two or three times a day.

PILULÆ FERRI IODIDI, *U. S., Br.*—PILLS OF IODIDE OF IRON.

Pilules d'iodure de fer, P. de Blancard, Fr.; Eisenjodür-Pillen, G.

Preparation.—Reduced Iron 60 grains (4.00 Gm.); Iodine 80 grains (5.20 Gm.); Glycyrrhiza, in No. 60 powder, 50 grains (3.25 Gm.); Sugar, in fine powder, 50 grains (3.25 Gm.); Extract of Glycyrrhiza, in fine powder, 12 grains (0.75 Gm.); Acacia, in fine powder, 12 grains (0.75 Gm.); Water, Balsam of Tolu, Stronger Ether, each a sufficient quantity; to make 100 pills. To the reduced iron, contained in a porcelain capsule, add about 120 grains or about 8 Gm. of water, and gradually add the iodine, constantly triturating, until the mixture ceases to have a reddish tint. Then add the remaining powders, previously mixed, and evaporate the excess of moisture on the water-bath, constantly stirring, until the mass has acquired a pilular consistence. Lastly, divide it into 100 pills. Dissolve 1 part of balsam of Tolu in 1 part of stronger ether; shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally stirring them until the drying is completed. Keep the pills in a well-stopped bottle.—*U. S.*

Take of fine iron wire 40 grains; iodine 80 grains; refined sugar, in powder, 70 grains; liquorice-root, in powder, 140 grains; distilled water 50 minims. Agitate the iron with the iodine and the water in a strong stoppered ounce phial until the froth becomes white. Pour the fluid upon the sugar in a mortar, triturate briskly, and gradually add the liquorice.—*Br.*

The first process, as compared with that of the former Pharmacopœia, has been modified in several particulars, though the strength of the pills remains unaltered. In directing a large excess of reduced iron, of which, if pure, 17 grains would suffice for combining with the iodine, filtration of the solution of ferrous iodide is rendered unnecessary; but owing to the heat produced by the reaction the iodine should be cautiously added in small quantities, to avoid loss by vaporization. Due precaution being exercised, the quantity of water directed in this part of the process may well be reduced to one-half or less, as has been done by the British Pharmacopœia, whereby subsequent evaporation may be avoided or materially lessened; if evaporation be necessary, the ferrous iodide is sufficiently protected by the excess of iron and by sugar, and without the presence of the other vegetable powders, which may be easily incorporated with the syrupy liquid. Owing to the gradual oxidation when exposed to the air, the pill mass should not be kept on hand, but should be at once made into pills. To protect these against the influence of the air, they are directed to be coated with a thin layer of Tolu balsam, or, according to the French Codex, with Tolu balsam and mastic, used in ethereal solution. The latter authority, whose process has, in the main, been adopted by the *U. S. P.*, with several improvements, does not require an excess of iron to be incorporated with the pill mass.

but directs the freshly-made pills to be rolled in finely-powdered iron, and afterward to be coated as stated, thus affording an additional protection to the surface of the pill.

If properly made and preserved, these pills will keep for years without acquiring the smell of iodine or tarnishing a strip of bright metal suspended in the vial. Should oxidation take place to the extent of liberating iodine, distilled water on being triturated with a few of the pills will yield a filtrate which, on the addition of gelatinized starch, will acquire a more or less distinct green tint, resulting from the brown-yellow color of the extractive matter and the blue color of iodide of starch.

Each pill contains very nearly 1 grain (0.063 Gm.), *U. S. P.*, or about $\frac{3}{4}$ grains (0.05 Gm.), *F. Cod.*, of ferrous iodide. 1 grain of the same compound is contained in $3\frac{1}{2}$ grains of the pill mass.—*Br.*

Medical Action and Uses.—Each of these pills contains about a grain of iodide of iron and one-fifth of a grain of reduced iron, and may be used for the purposes to which iodide of iron in other forms is applied. They are reported to be useful in *anæmia* and the *scrofulous* or *tuberculous* diathesis, but the opinion is founded rather on hypothetical notions than upon clinical experience. In point of fact, glandular scrofula and pulmonary tuberculosis are neither identical nor closely allied, and while iodine and iron are both useful in the former, they are usually injurious in the latter, except when iron is demanded by the anæmic state of the system; but neither of them touches the root of the disease. *Dose*, from 3 to 8 grains (Gm. 0.20–0.40).

PILULÆ GALBANI COMPOSITÆ, *U. S.*—COMPOUND PILLS OF GALBANUM.

Pilula asafetidæ composita, *Br.*; *Compound pill of asafetida*, *E.*; *Pilules de galbanum composées*, *Fr.*; *Galbanum-Pillen*, *G.*

Preparation.—Galbanum 150 grains (9.75 Gm.); Myrrh 150 grains (9.75 Gm.); Asafetida 50 grains (3.25 Gm.); Syrup a sufficient quantity; to make 100 pills. Beat them together so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use galbanum and myrrh, of each 18 grains (1.17 Gm.), asafetida 6 grains (0.39 Gm.).

Take of asafetida, galbanum, myrrh, each 2 ounces; treacle, by weight, 1 ounce. Heat all together by means of a water-bath, and stir the mass until it assumes a uniform consistence.—*Br.*

A similar pill was formerly official in France as *Pilules antihystériques*.

Medical Action and Uses.—The ingredients of this compound render it more or less stimulant to the mucous membrane, and especially appropriate in chronic *pulmonary catarrh* and *uterine leucorrhœa*. It is also used in functional nervous disorders, especially of an hysterical nature. *Dose*, from 5 to 20 grains (Gm. 0.30–1.30) or from 2 to 4 pills.

PILULA IPECACUANHÆ CUM SCILLA, *Br.*—PILL OF IPECACUANHA AND SQUILL.

Preparation.—Take of Compound Powder of Ipecacuanha 3 ounces; Squill, in powder, Ammoniacum, in powder, each 1 ounce; Treacle a sufficiency. Mix the powders, and beat into a mass with the treacle.—*Br.*

Medical Action and Uses.—The presumed effect of this pill is to mitigate *bronchitis* in its chronic, and especially its senile forms, by a combined sedative and stimulant action. There can be no question of its utility in many cases for which the balsams and terebinthines are too stimulating. *Dose*, from 5 to 10 grains (Gm. 0.30–0.60).

PILULÆ OPII, *U. S.*—PILLS OF OPIUM.

Pilules d'opium, *Fr.*; *Opiumpillen*, *G.*

Preparation.—Powdered Opium 100 grains (6.50 Gm.); Soap, in fine powder, 25 grains (1.62 Gm.); to make 100 pills. Beat them together with water, so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use powdered opium 12 grains (0.78 Gm.) and soap 3 grains (0.195 Gm.).

Medical Action and Uses.—Very often opium in substance is more suitable than any of its liquid preparations or than the salts of morphine. This is especially the case when it is desirable to limit the action of the medicine, as far as possible, to the *stomach* and *bowels* in painful affections of those viscera, and in cases of *vomiting* and *purging*, such as occur in *cholera morbus*, *ulcer of the stomach*, *gastralgia*, *typhoid fever*,

etc. In most of these diseases the efficiency of the medicine is increased by its slow solution, and hence in them an old opium pill is greatly preferable to a freshly-made one. One pill may be given for a dose, and repeated if necessary.

PILULÆ PHOSPHORI, U. S., Br.—PHOSPHORUS PILLS.

Pilules au phosphore, Pilules phosphorées, Fr.; Phosphorpillen, G.

Preparation.—Phosphorus 1 grain (0.06 Gm.); Althæa, in No. 60 powder, 80 grains (5.20 Gm.); Acacia, in fine powder, 20 grains (1.30 Gm.); Glycerin 40 grains (2.60 Gm.); Water 20 grains (1.30 Gm.); Purified Chloroform 50 grains (3.20 Gm.); Balsam of Tolu, Stronger Ether, each a sufficient quantity; to make 100 pills. Dissolve the phosphorus in the chloroform in a test-tube. Mix the althæa and the acacia in a mortar with the pestle, add the solution of phosphorus, then the glycerin and the water, and quickly form a mass, to be divided into 100 pills. Dissolve 1 part of balsam of Tolu in 1 part of stronger ether, shake the pills with a sufficient quantity of the solution until they are uniformly coated, and put them on a plate to dry, occasionally stirring until the drying is completed. Keep the pills in a well-stopped bottle.—U. S.

Take of phosphorus 3 grains; balsam of Tolu 120 grains; yellow wax 57 grains. Put the phosphorus and balsam of Tolu into a Wedgewood mortar about half full of hot water, and, when the phosphorus has melted and the balsam has become sufficiently soft, rub them together beneath the surface of the water until no particles of phosphorus are visible, the temperature of the water being maintained at or near to 140° F.; add now the wax, and as it softens mix it thoroughly with the other ingredients. Allow the mass to cool without being exposed to the air, and keep it immersed in cold water in a bottle. When dispensed, incorporate 2 grs. of the mass with curd soap 1 gr.; if necessary, soften with spirit.—Br.

Phosphorus requires to be kept under water and to be weighed out under a liquid in which it is not oxidized, either water or chloroform. By melting a small quantity of phosphorus under warm water contained in a vial, and then agitating it well until the phosphorus has solidified, this is obtained in small granules, which are conveniently handled, and after having been rapidly dried with filtering-paper are at once dropped into the previously tared liquid until the desired quantity has been obtained.

Tolu as a vehicle for phosphorus in pills was proposed by A. C. Abraham (1874), who observed that it will retain 4 per cent. of the latter if combined with it in the melted condition. A. W. Gerrard (1873) had previously made a similar observation with regard to rosin, and this preparation became known at the time as *phosphoretted resin*; it is prepared by melting the resin in a wide-mouthed vial, adding the requisite quantity of phosphorus, and when it has melted agitating the stoppered vial until the phosphorus is dissolved. Like resin, it may be powdered, and, like the pill mass of the British Pharmacopœia, it should be kept under water to prevent oxidation. W. H. Walling (1875) found cacao butter very serviceable; 300 grains of it are melted in a vial, 25 grains of phosphorus are added, the vial is corked and well agitated until solution has been effected, and afterward with 200 grains of powdered soap until a uniform mixture is obtained. E. Lilly (1876) suggested fusing 6 parts of phosphorus under 260 parts of syrup, agitating well to effect its fine division, and incorporating with 340 parts of flour; formulas similar to this one are often followed in Europe. W. B. Addington (1875) proposed to dissolve the phosphorus in sufficient bisulphide of carbon, and to incorporate the solution in a mortar with a suitable extract, continuing the trituration until the solvent has evaporated; the extract may be replaced by soap, resin, or other suitable material. This process has been adopted by the U. S. Pharmacopœia, which, however, uses the far preferable chloroform as a solvent, which, aside from its odor, has the advantage of not being inflammable, while its vapor prevents the oxidation of the phosphorus. (See PHOSPHORUS.)

Medical Action and Uses.—This is one of the forms in which phosphorus may be prescribed internally. *Dose*, from 3 to 6 grains (Gm. 0.20–0.40), or one or two pills.

PILULA PLUMBI CUM OPIO, Br.—PILL OF LEAD AND OPIUM.

Preparation.—Take of Acetate of Lead, in fine powder, 36 grains; Opium, in powder, 6 grains; Confection of Roses, 6 grains. Beat them into a uniform mass.—Br.

Medical Action and Uses.—2½ grains of acetate of lead and ½ grain of opium are contained in every 3 grains of this mass. The association of the two medicines is of great benefit in chronic *diarrhœa*, *dysentery*, and *bronchitis*, but as the proportion in which

they ought to be employed should vary in almost every case, a fixed formula for their union appears superfluous. *Dose*, from 3 to 5 grains (Gm. 0.20–0.30).

PILULA QUININÆ.—PILL OF QUINIA.

Pilules de quinine, Fr.; *Chininpillen*, G.

Preparation.—Take of Sulphate of Quinia 60 grains; Confection of Hips 20 grains. Mix them to a uniform mass.—*Br.* 1867.

The quinine pills (U. S. P. 1870) contained 1 grain of the sulphate, and, like those of the French Codex, were made with clarified honey; the pills of the latter authority contain $1\frac{1}{2}$ grains (0.10 Gm.) of the salt. The Pharmacopœia of 1880 has very properly dismissed the old formula. Since these pills are usually desired white, the mass is often made with simple syrup or glycerin, using at the same time a minute quantity of powdered acacia or tragacanth; or glycerite of starch is employed as an excipient. Sulphate of quinine may also be made into pills by the aid of aromatic sulphuric acid, of which 12 to 15 drops are required for 20 grains of the salt, as proposed by Parrish (1853). The mixture is at first quite soft, but soon becomes plastic, and may then be rapidly rolled out and divided; the previous addition of 1 or 2 drops of syrup will keep it soft for a short time. Other dilute acids, except acetic acid, may be substituted for the sulphuric acid, or, if solid, like citric and tartaric acids, may be incorporated with about five or ten times their weight of the salt in the dry state, and formed into a mass by the addition of a liquid.

Medical Action and Uses.—Pills of sulphate of quinine are not, generally, as efficient as liquid preparations of the salt, particularly if they have become hardened by age. The use of the disulphate obviates this objection partially, and the lenticular or compressed pills made with it are very efficient. These pills are better adapted for securing the tonic than the anti-periodic or febrifuge operation of quinine. They should be taken either immediately before or after a meal, especially when the stomach is irritable. The ordinary *dose* is one pill, containing 1 grain (Gm. 0.06) of the sulphate.

PILULÆ RHEI, U. S.—PILLS OF RHUBARB.

Pilules de rhubarbe, Fr.; *Rhabarberpillen*, G.

Preparation.—Rhubarb, in fine powder, 300 grains (19.50 Gm.); Soap, in fine powder, 100 grains (6.50 Gm.); to make 100 pills. Beat them together with water so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use rhubarb 36 grains (2.34 Gm.), soap 12 grains (0.78 Gm.).

Soap is an excellent excipient for rhubarb and many other powders.

Medical Action and Uses.—One of these pills, containing 3 grains of rhubarb, acts as a mild laxative, especially when taken after a meal or at bedtime, unless the constipation be very decided. They are generally prescribed to relieve slowness of defecation rather than actual constipation. *Dose*, from one to three pills.

PILULÆ RHEI COMPOSITÆ, U. S., *Br.*—COMPOUND PILLS OF RHUBARB.

Compound rhubarb pill, E.; *Pilules de rhubarbe composées*, Fr.; *Rhabarber und Aloe-pillen*, G.

Preparation.—Rhubarb, in No. 60 powder, 200 grains (13.00 Gm.), Purified Aloes, in fine powder, 150 grains (9.75 Gm.); Myrrh, in fine powder, 100 grains (6.50 Gm.); Oil of Peppermint 10 grains (.65 Gm.); to make 100 pills. Beat them together with water so as to form a mass, and divide it into 100 pills.—*U. S.* For 12 pills use rhubarb 24 grains (1.56 Gm.); aloes 18 grains (1.17 Gm.); myrrh 12 grains (0.78 Gm.); oil of peppermint 1 grain (about 2 drops).

Take of rhubarb-root, in powder, 3 ounces; Socotrine aloes, in powder, $2\frac{1}{2}$ ounces; myrrh, in powder, hard soap, in powder, each $1\frac{1}{2}$ ounces; oil of peppermint $1\frac{1}{2}$ fluidrachms; glycerin 1 ounce; treacle about 3 ounces. Mix the powders with the oil, then add the glycerin and sufficient treacle, and beat the whole into a uniform mass.—*Br.*

Medical Action and Uses.—Compound pills of rhubarb are among the best medicines for the relief of habitual *costiveness* depending upon atony of the large intes-

tine and flatulent dyspepsia. *Flatulence*, whether gastric or intestinal, is a serious hindrance to the proper movements of the muscular walls of the digestive canal, tending to hinder the progress of the alimentary or fecal mass and increase its fermentation, with the production of gas or of the acrid and irritating products of its decomposition. Such results are more or less prevented by the stimulating operation of medicines of which these pills are an example. *Dose*, from one to four pills.

PILULA SAPONIS COMPOSITA, *Br.*—COMPOUND PILL OF SOAP.

Pilula opii, *Br.* 1864.

Preparation.—Take of Opium, in powder, $\frac{1}{2}$ ounce; Hard Soap, in powder, 2 ounces; Glycerin a sufficiency. Mix the opium and soap, and beat into a mass with the glycerin.—*Br.*

Compound soap pill (*U. S. P.* 1870) was identical with this, but was prepared with water in the place of glycerin.

Medical Action and Uses.—This preparation contains 1 grain of opium in 5 of the mass. Its merit is supposed to consist in its ready solubility in the gastric juices and in its being a convenient vehicle for prescribing opium under another name. *Dose*, from 3 to 5 grains (*Gm.* 0.20–0.30), or one or two pills.

PILULA SCAMMONII COMPOSITA, *Br.*—COMPOUND SCAMMONY PILL.

Pilules de scammonée composées, *Fr.*; *Scammoniumpillen*, *G.*

Preparation.—Take of Resin of Scammony, Resin of Jalap, Curd Soap, in powder, each 1 ounce; Strong Tincture of Ginger 1 fluidounce; Rectified Spirit 2 fluidounces. Add the spirit and tincture to the soap and resins, and dissolve with the aid of a gentle heat; then evaporate the spirit by the heat of a water-bath until the mass has acquired a suitable consistence for forming pills.—*Br.*

The process adopted furnishes a very good pill mass, in which the resins are uniformly divided through the agency of the soap, which also keeps them in suspension when the mass is macerated with water. A similar preparation, which does not contain scammony, has been in use for a long time in continental Europe. (See *RESINA JALAPÆ*.)

Medical Action and Uses.—In this preparation the compound powder of scammony assumes a pilular form. It may be prescribed when drastic purgation is required in *dropsy*, *congestion of the brain or liver*, etc. *Dose*, from 5 to 15 grains (*Gm.* 0.30–1).

PILULA SCILLÆ COMPOSITA, *Br.*—COMPOUND SQUILL PILL.

Pilules de scille composées, *Fr.*; *Meerzwiebelpillen*, *G.*

Preparation.—Take of Squill, in powder, $1\frac{1}{2}$ ounces; Ginger, in powder, Ammoniac, in powder, Hard Soap, in powder, each 1 ounce; Treacle, by weight, 2 ounces or a sufficiency. Mix the powders, add the treacle, and beat into a uniform mass.—*Br.*

Compound pills of squill (*U. S. P.* 1870) contained each squill $\frac{1}{2}$ grain, ginger 1 grain, ammoniac 1 grain, and soap $1\frac{1}{2}$ grains.

Medical Action and Uses.—The stimulant action of these pills upon the bronchial mucous membrane makes them appropriate in the treatment of *chronic bronchitis* when it is attended with excessive secretion. The ginger in the compound probably renders it less hurtful to the stomach than it would be without that ingredient. *Dose*, two pills two or three times a day.

PIMENTA, *U. S.*, *Br.*—PIMENTO.

Semen amomi, *Piper jamaicense*.—*Allspice*, *E.*; *Piment de la Jamaïque*, *Toute-épice*, *Fr.*; *Nelkenpfeffer*, *Englisches Gewürz*, *Neugewürz*, *G.*

The nearly ripe fruit of *Eugenia Pimenta*, *De Candolle*, s. *Myrtus Pimenta*, *Linné*, s. *Pimenta officinalis*, *Lindley*, s. *P. vulgaris*, *Wight et Arnott*. Bentley and Trimen, *Med. Plants*, 111.

Nat. Ord.—Myrtaceæ.

Origin.—The allspice tree is indigenous to the West Indies, Central America, and the northern part of South America, and has been introduced into other tropical countries.

It is slender, 30 to 40 feet (9–12 M.) high, has opposite, entire, oblong or oval oblong, obtuse, and pellucid punctate leaves, and small white racemose flowers, the terminal ones being sessile and the lateral ones peduncled. The fruit is collected before it is ripe, but after it has attained its full size. 1,774,344 pounds of allspice were imported into the United States in 1881.

Description.—Allspice is nearly globular, $\frac{1}{4}$ inch (6 Mm.) or less in diameter, and crowned above with the short four-parted calyx limb, or marked by its remnants, which surround a shallow depression containing a short style. The pericarp is of a reddish-brown or brown-gray color, and a granular appearance externally, lighter internally, woody, but thin and fragile, and contains numerous oil-cells. The berry has two cells, each with a single brown, plano-convex, roundish-reniform seed enclosing the spirally-curved, dark purplish-brown embryo. Allspice has an agreeable pungently aromatic odor and taste, with a flavor resembling that of cloves.

Constituents.—The most important constituent is the volatile oil (see *OLEUM PIMENTÆ*), of which the fruit yields 3 to 4 per cent. Bonastre (1826) examined the fruit deprived of the seeds, and the latter separately, and obtained from them 10 to 5 per cent., respectively, of volatile oil; they also contain resin, tannin, fixed oil, sugar, mucilage, etc.

Off. Prep.—*Aqua pimentæ*, *Syrupus rhamni*, *Br.*

Medical Action and Uses.—Pimento is an aromatic stimulant, and, like other agents of its class containing an essential oil, is used as a condiment to stimulate the digestive organs when they are suffering from exhaustion, and particularly from the debility caused by the prolonged heat of summer in tropical regions. In medical practice it is chiefly employed to relieve *flatulence*, to augment the effect of vegetable tonics, and to correct the tendency of purgatives to produce griping, or to cover the nauseous taste of certain medicines. It may be given in infusion, but the oil is more generally used. Like capsicum, pimento may be incorporated with Burgundy pitch or lead plaster to produce local stimulant, anodyne, and revulsive effects in *neuralgia* and *rheumatism*, or the extract itself may be spread upon cloth. Its application rapidly produces a sense of warmth in the part to which it is applied, followed by smarting and redness.

FIG. 220.

Pimenta officinalis, Lindley.

PIPER, U. S.—BLACK PEPPER.

Piper nigrum, Br.—*Poivre noir (commun)*, Fr.; *Schwarzer Pfeffer*, G.

The unripe berries of *Piper nigrum*, Linné. Bentley and Trimen, *Med. Plants*, 245.
Nat. Ord.—Piperaceæ.

Origin.—Black pepper is a climbing shrub about 20 feet (6 M.) high, indigenous to India, and at present cultivated in most of the East Indian and Philippine and some of the West Indian islands. It has smooth, alternate, petiolate, ovate acute, and entire, five- or seven-nerved leaves, opposite to which elongated spikes of monoecious or dioecious flowers are produced, followed by sessile, berry-like fruits, which change from green to red, and finally yellow. The spikes are gathered as soon as some of the fruits begin to turn red; the next day the berries are rubbed off with the hands, and dried either near a fire or in the sun. About 9,000,000 pounds of black and white pepper and about 5000 pounds of ground pepper are annually imported into the United States; in 1883 the importation of the former was nearly 7,000,000 pounds.

Description.—Black pepper is globular, about $\frac{1}{8}$ inch (4 Mm.) in diameter, reticulatedly wrinkled on the surface from the dried and contracted thin sarcocarp, blackish-brown or grayish-black externally, lighter colored internally, and encloses a single globular seed, which is whitish, mealy, and contains an undeveloped embryo in a central cavity. Pepper has a peculiar aromatic odor and a hot and pungent taste. *Piper tricozum*, Roxburgh, of India, yields a very similar fruit.

Constituents.—Black pepper was examined by Oersted (1819), who announced the discovery of *piperine*, and by Pelletier and Poutet (1820), who recognized the presence

of volatile oil, acrid resin, starch, gum, etc. Willert (1817) ascribed the acrid taste to the soft resin, which conclusion was corroborated by Pelletier. According to Buchheim

FIG. 221.

Piper nigrum, Linné.

(1876), pepper contains a second alkaloid, *chavicine*, which may be obtained from the ethereal solution of the alcoholic extract by agitating it with potassa solution to remove chlorophyll, resin, and fat acids, and evaporating; fat is removed by treatment with benzin, and piperine is left behind by repeated solution in a little ether. Thus obtained, chavicine is yellowish-brown, of the consistence of turpentine, has a strongly acrid taste, and when in alcoholic solution, boiled with potassa, is said to yield *piperidine* (see below) and amorphous *chavicic acid*. Lecanu obtained 1.17 per cent. of volatile oil from black and 1.04 per cent. from white pepper. Oil of pepper is colorless, lighter than water, commences to boil at 167.5° C. (333.5° F.), and was found by Dumas (1835) to be isomeric with oil of turpentine. It has the odor of pepper, but is destitute of its pungent taste, and yields with dry hydrochloric acid gas a liquid compound.

The *pungent resin* is dark-green, soluble in alcohol, ether, and alkalies, and, in connection with other constituents of pepper, also in water. Pepper yields about 5 per cent. of ash.

Adulterations.—Ground pepper is frequently adulterated with various farinaceous substances, the press-cake of flaxseed, capsicum, and other materials. The adulterations are best detected by the microscope. With the view of determining the presence of adulterations in ground pepper, A. W. Blyth (1874) examined

black pepper from five different localities, with the following results: Loss by the heat of a water-bath (moisture and volatile oil), 9.531 to 12.908, mean 10.95 per cent.; ash (for dried pepper), total, 4.189 to 5.770, mean 4.845 per cent., and soluble in water, 2.212 to 3.453, mean 2.84 per cent.; alcoholic extract, dried, 6.30 to 7.836, mean 6.922 per cent.; hot-water extract, 16.50 to 20.375, mean 18.177 per cent.

Other Peppers.—*PIPER ALBUM*, *White pepper*, consists of the ripe fruit of black pepper, which is immersed in water and with the hands deprived of the epicarp and sarcocarp. It consists of the seed, which is composed of a large white mealy perisperm united at the apex with a small endosperm, in which the embryo is enclosed, the whole being enclosed in the reddish-brown testa, and this is covered with the white, soft, inner tissue of the fruit, in which about ten light lines are observable running from the base toward the apex. White pepper is rather larger and less pungent than black pepper, but contains the same constituents. A factitious white pepper is said to have been sometimes put into the market, made from black pepper by rubbing off the outer layers: it is easily recognized by its smaller size and large central cavity. White pepper yielded to Blyth 7.650 per cent. of alcoholic extract, but only 1.120 per cent. of ash, one-half of which was soluble in water.

PIPER LONGUM, *Long pepper*, consists of the spikes of *Piper* (*Chavica*, *Miquel*) *officinatum*, *De Candolle*, which is indigenous to Java. The nearly-allied *Piper longum*, *Linné*, s. *Chavica Roxburghii*, *Miquel* (Bentley and Trimen, *Med. Plants*, 244), is likewise a shrub, but is found in India, Ceylon, and the Philippines. The spikes of the full-grown but still immature fruits are collected: they are 1 to 1½ inches (25–38 Mm.) long, nearly cylindrical, covered with the closely-packed, coalesced fruits, and agree with black pepper in odor, taste, and composition. In the amount of hygroscopic moisture and hot-water extract long pepper gives results agreeing with those mentioned above: but Blyth obtained 2.60 per cent. of alcoholic extract and 8.308 per cent. (4.472 soluble in water) of ash.

PIPER (MACROPIPER, Miquel) METHYSTICUM, Forster. (See page 964.)

PIPER RETICULATUM, Linné, has a pungently aromatic root, which is employed in Brazil for its stimulating properties.

PIPER (CHAVICA, Miquel) BETLE, Linné. (See page 964.)

PIPER (CHAVICA, Miquel) SIRIBOA, Linné, has leaves which are used like the preceding, and are of a similar appearance, but less distinctly heart-shaped.

PIPER (ARTANTHE, Miquel) CROCATUM, Ruiz et Pavon. It is indigenous to Peru: the leaves and berries have a peppery taste; the ripe spikes are employed for dyeing yellow.

PIPER ANISATUM, Kunth. It is found in the northern part of South America: the leaves and berries have an anise-like taste.

Off. Prep.—Confectio piperis, Br.; Oleores. piperis, U. S., Br.; Pulv. opii comp. Br.

Medical Action and Uses.—Pepper is a powerful local and general stimulant, a quality which it owes to its concrete and volatile oils, and it also probably exerts a special and more sustained influence upon the nervous system through its peculiar principle, piperine. Applied to the skin, powdered pepper occasions severe pain and redness; in the mouth and throat in large quantities it excites intense burning, and in the stomach a sense of diffusive warmth with some acceleration of the pulse. In very large doses it excites a burning heat throughout the abdomen, thirst and vomiting, sometimes fever, and occasionally convulsions. In some cases heat and tingling are felt in the palms of the hands and in the soles of the feet, followed by a sense of coolness in these parts. It augments the urine and irritates the bladder and urethra, and it may produce a transient eruption of urticaria upon the skin.

Black pepper is, of all condiments except salt, the most extensively used to facilitate the digestion of soups and watery vegetables. Anciently, it was one of the most approved remedies for *intermittent fever*, and in modern times a large number of examples attest its efficacy, both in the form of the crude drug and as piperine. There can be no doubt that in many cases it has effected complete cures, but it is more generally employed in connection with quinine when the latter alone has failed, and often with advantage. Whether its efficiency is due to its own anti-periodic properties, or to its rendering the system more susceptible to the action of quinine, is undecided. Pepper is sometimes used in poultices to promote the resolution of enlarged *lymphatic glands*; in gargles to stimulate the *throat* and *gums* in flaccid conditions of these parts; and in plasters for the relief of *muscular rheumatism* and to assuage *headache*, *colic*, and other local pains. In powder it has been used to destroy *head lice*. Anciently, it was employed as a topical application to *hemorrhoids*, and in recent times the confection of pepper has been given internally for a like purpose. In some cases of *fistula in ano*, of *gleet*, and of *leucorrhœa* it has been found very serviceable.

Powdered pepper may be given as a stomachic stimulant in *doses* of from 5 to 20 grains (Gm. 0.30–1.30), or as a condiment mixed with food. As an anti-periodic eight or ten pepper-corns may be taken two or three times a day.

PIPERINA, U. S.—PIPERINE.

Piperinum.—*Pipérine*, Fr.; *Piperin*, G.

Formula $C_{17}H_{19}NO_3$. Molecular weight 285.

Origin.—Piperine was discovered by Oerstedt (1819), and obtained pure by Pelletier and Poutet (1820). It has been prepared from black, white, and long pepper, and by Stenhouse (1855) from the fruit of *Cubeba Clusii*, *Miguel*.

Preparation.—It is most readily prepared from the alcoholic extract of white pepper by treating it with potassa solution, which dissolves the resin, washing the residue with water, and purifying it by repeated crystallization from alcohol. On neutralizing the potassa solution with an acid the pungent resin is obtained. Wittstein's process is as follows: 16 parts of black pepper are exhausted with cold water, and afterward with alcohol; the alcoholic extract is washed with water, digested with alcohol and 1 part of slaked lime, and the solution concentrated; the crystals are purified by recrystallization and treatment with animal charcoal. The yield varies between 5 and 9 per cent.

Properties.—Pure piperine crystallizes in colorless flat, four-sided prisms of a glassy lustre and almost tasteless. As usually met with, it is of a yellowish color, inodorous, and has at first a slight, but on continued mastication or in alcoholic solution a sharp, peppery taste. It remains unaltered on exposure, has a neutral reaction to test-paper, is nearly insoluble in water, and dissolves in volatile oils, in 60 parts of cold ether (Merck), in 30 parts of cold and in 1 part of boiling 80 per cent. alcohol (Wittstein), and freely in acetic acid; the last two solutions are precipitated on the addition of water. It is likewise soluble in chloroform, benzol, and benzin. At 129° C. (264.2° F.) it melts like wax to a yellowish oily liquid, which on cooling congeals to a mass of resinous appearance; when fused it may be ignited and burns with a bright flame, leaving a light charcoal, which is readily consumed by heating it in the air. Sulphuric acid colors it blood-red, the color disappearing on the addition of water, leaving the piperine unaltered if the action of the acid had not been prolonged (Pelletier). The solution of piperine in sulphuric acid is yellow, becoming dark-brown, and finally green-brown (Dragendorff). Nitric acid colors piperine successively greenish-yellow, orange, and red, and dissolves it with a yellow color, the solution separating yellow floccules on the addition of water; by

prolonging the action of the acid oxalic acid and a yellow bitter compound are produced (Pelletier). The resin resulting from this reaction becomes blood-red on the addition of potassa, and on heating the mixture piperidine is given off (Anderson, 1850). Piperine is a very weak base, and its salts are decomposed by water; crystallizable double salts, soluble in alcohol, may be obtained with the chlorides of mercury, platinum, and cadmium. By dry distillation with soda-lime piperidine is obtained. Boiled with alcoholic solution of potassa, piperine was found by Babo and Keller (1856) to be resolved into *piperic acid*, $C_{12}H_{10}O_4$, and *piperidine*, C_5H_9N . Piperic acid is in hair-like yellowish needles which fuse at 150° C. (302° F.), and at a higher temperature volatilize partly unaltered, at the same time giving off a coumarin-like odor. Piperidine is a colorless liquid of an ammoniacal and pepper-like odor, and when largely diluted of a bitter taste. It boils at 106° C. (222.8° F.), has a strong alkaline reaction, dissolves freely in water and alcohol, and yields with acids crystallizable salts; the piperate of piperidine crystallizes in silky scales, which, on being heated, give off a part of the alkaloid. Ladenburg (1884) obtained a small quantity of piperidine synthetically by treating an alcoholic solution of pyridine with sodium.

Dose. Piperine may be given in doses of from 1 to 10 grains (Gm. 0.06–0.60).

PISCIDIA.—PISCIDIA.

Jamaica dogwood, E.; *Piscidie*, Fr., G.

The bark of the root of *Piscidia Erythrina*, Jacquin.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—This is a West Indian tree, about 20 feet (6 M.) high. It has imparipinnate leaves, with about seven ovate entire leaflets, and paniculate racemes of whitish and deep-red flowers, producing linear four-winged racemes. The wood of the trunk is heavy, brown, coarse-grained, and very durable.

Description.—*Piscidia*-bark comes in quills about $\frac{1}{2}$ inch (12 Mm.) in diameter, or in flat or curved sections 1 or 2 inches (25 or 50 Mm.) broad, 4 or 6 inches (10 or 15 Cm.) long, and from $\frac{1}{12}$ to $\frac{1}{6}$, rarely $\frac{1}{4}$ inch (2 to 4 or 6 Mm.) thick. It is covered with a corky layer having a bright orange-brown, or occasionally a whitish, color, and a roughish wrinkled or somewhat fissured appearance. When the cork is detached the outer surface of the bark is of a dark ash-gray color, with a brown or blackish tint, and has slight wavy longitudinal wrinkles and thin transverse ridges. The inner surface is brownish and smooth, or from the bared bast-bundles more or less fibrous. In the interior the tissue is of a brownish-green or blue-green color, apparently due to chlorophyll contained in the parenchyma. The bark consists mainly of the liber, in which the transversely elongated bast-bundles are arranged in irregular circles separated by parenchyma, and in radial rows between the rather broad medullary rays. It breaks with a tough fibrous fracture, the bast-bundles adhering in bands. When broken, the bark has a narcotic odor, resembling that of opium; the taste is at first slight, afterward bitter and acrid.

Constituents.—The active principle, according to E. Hart (1883), is a neutral compound, *piscidin*, $C_{26}H_{24}O_8$, which may be obtained from the concentrated tincture by treating it with lime, filtering, adding a little water, and crystallizing; after recrystallization from alcohol it forms colorless prisms, which melt at 192° C. (377.6° F.), are insoluble in water, slightly soluble in ether and in cold alcohol, and easily soluble in benzol and chloroform. It is not a glucoside. The other constituents have not been investigated. Resinous and oily compounds are present, and crystals of calcium oxalate are observed in the tissue.

Pharmaceutical Uses.—EXTRACTUM PISCIDIÆ FLUIDUM. Fluid extract of *piscidia*, may be prepared in the same manner as fluid extract of *serpentaria*, using a menstruum composed of 3 parts of alcohol and 1 part of water.

Medical Action and Uses.—The bark of *Piscidia erythrina* was first known in Europe as having been used in the West Indies to catch fish by benumbing them (Wibmer, *Wirkung d. Arzneimittel*, iv. 222). Many years ago (1844), in England, Dr. Hamilton took a drachm of the tincture of this bark while suffering from a severe tooth-ache. It caused a burning sensation in the stomach and copious perspiration, followed by deep sleep. He also applied it with success to aching carious teeth (*Jour. Phil. Coll. Phar.*, v. 159). It appears to have been lost sight of until 1880, when it was stated to be a powerful anodyne, relaxing the system, producing salivation and sweating, and affording marked relief in neuralgia of the face (*Phil. Med. Times*, xi. 57). In 1881 the experiments of Dr. Isaac Ott led him to conclude that *piscidia* contains a narcotic

principle which does not affect the motor nerves, but acts on the sensory ganglia of the spinal cord, producing convulsions, partly by stimulating the cord and partly by heightening the excitability of the muscles. He also found that it reduces the frequency of the pulse by a direct action upon the heart, first increasing and then diminishing the arterial tension, and that it first contracts and then dilates the pupils (*Medical News, etc.*, xxxix. 212). It has had the credit of curing or relieving *neuralgia* (*Louisville Med. News*, June 5, 1880), but sufficient proof of its virtues is wanting. It should be remembered that of all affections neuralgia is perhaps the one most frequently relieved—for the time—by faith. Seifert used an extract of piscidia which, when given in the dose of from 4 to 8 grains (Gr. 0.20–0.40) to relatively healthy persons, caused sound sleep, after which some lightness of the head was felt, as after a dose of morphine; but it did not affect the pulse or temperature. In two cases of phthisis in which morphine had ceased to allay the cough this medicine palliated it, and in others in which no morphine had been used it acted in a similar manner, but in one instance it occasioned sweats which were checked by atropine. In several other affections its utility was less evident (*Centralbl. f. d. ges. Therapie*, i. 427). In trials made by Berger the results were entirely negative (*Ibid.*, ii. 121).

PIX BURGUNDICA, U. S., Br.—BURGUNDY PITCH.

Poix de Bourgogne, Poix blanche, Fr.; Burgunder Harz (Pech), G.

The prepared resinous exudation from the spruce fir, *Abies* (*Pinus, Lamarck, Picea, Link*) *excelsa, De Coudolle*, s. *Pinus Abies, Linné*, s. *Pinus Picea, Du Roi*. Woodv., *Med. Bot.*, pl. 208; Bentley and Trimen, *Med. Plants*, 261.

Nat. Ord.—Coniferæ.

Origin.—The *spruce fir*, or *Norway spruce fir*, is a stately tree attaining a height of 150 to 180 feet (50–60 M.), and growing in Northern Asia and Northern Europe, and in the latter continent southward in mountainous regions to the Pyrenees and Alps; it is frequently cultivated in the United States. It has spreading, nearly horizontal branches, pendulous branchlets, scattered, somewhat four-angled leaves, about $\frac{3}{4}$ inch (19 Mm.) long, and pendulous, light-brown, nearly cylindrical cones, which are from 6 to 7 inches (15–17 Cm.) in length. The Siberian variety, *Picea* (*Pinus, Antoine*) *obovata, Ledebour*, differs mainly in having smaller and more slender ovate cones.

Collection.—The oleoresinous exudation of the spruce fir, which flows from incisions, is collected in Finland, South-western Germany, Austria, and Switzerland, and is melted in water and strained; but the manufacture is on the decline, at least in Germany. That collected in some districts of the Bernese Jura is known in commerce as *poix blanche* (*Pharmacographia*). During the year 1881–82, 147,053 pounds, and in the following year 35,356 pounds, of Burgundy pitch entered the United States.

Description.—Burgundy pitch is thus described by the British Pharmacopœia: “Hard and brittle, yet gradually taking the form of the vessel in which it is kept; opaque, varying in color, but generally dull reddish-brown; of a peculiar, somewhat empyreumatic perfumed odor and aromatic taste, without bitterness; free from vesicles: gives off no water when heated.” The following additional characters of true Burgundy pitch were ascertained by Hanbury (1867): “Fracture shining, conchoidal, translucent; some samples contain much water and are opaque and of a dull-gray color, and require straining to free them from impurities; not wholly soluble in alcohol of .838, but leaves a small amount of white flocculent matter; placed in contact with double its weight of glacial acetic acid in a vial, it is dissolved, with the exception of a small amount of flocculent matter.” The description of the U. S. Pharmacopœia agrees with the above.

Constituents.—Burgundy pitch contains *volatile oil*, which is most likely isomeric with oil of turpentine, and *resin*, which probably consists mainly of Maly's *abietic acid*. (See TEREBINTHINA.)

Adulterations and Substitutions.—The German Pharmacopœia has very properly dismissed Burgundy pitch; that of 1872 recognized the product of various species of *Abies*, which were not enumerated, under the designations *Resina pini, Resina pini burgundica*, and *Pix alba*, and gave the following description: “It is a yellow or yellowish-brown, opaque, or diaphanous, fragile resin, having a glossy fracture, becoming soft when held in the hand, of a terebinthinate odor, and almost completely soluble in alcohol.”

The substance commonly sold in England is made by melting together colophony with palm oil or some other fat, water being stirred in to render the mixture opaque (*Phar-*

macographia). Hanbury described artificial Burgundy pitch as varying in color between tawny-yellow, orange-yellow, and orange-brown. The fracture is wax-like or shining or conchoidal, always opaque, but becoming gradually transparent on the surface by the loss of water; the odor is weak, terebinthinous, and hardly aromatic; it is less soluble in alcohol .838, and with glacial acetic acid forms a turbid mixture which separates into two layers—a thick oily liquid above and a bright solution below.

Off. Prep.—Empl. ferri, U. S.; Br.; Empl. galbani, Empl. opii, U. S.; Empl. picis, Br.; Empl. picis burgundicæ, Empl. picis c. cantharide, U. S.

Medical Action and Uses.—Applied to the skin as a plaster, it produces itching, redness, and a papular eruption, and upon a delicate integument may occasion a vesicular, and even a pustular, eruption, with superficial ulcers. This eruption has been attributed to the retention by the impermeable plaster of the cutaneous secretions, but the better opinion is that it depends upon the inherent properties of the resin.

In the form of a plaster Burgundy pitch is in general use to protect, sustain, or stimulate the part to which it is applied. In most cases these several objects are attained together. Thus, in the popular use of it as a remedy for *lumbago* particularly, but of other forms also of *muscular rheumatism*, it supports the part mechanically, protects it from external impressions, and stimulates it to the production of perspiration, or even to the formation of an eruption, as already mentioned. In the latter way it acts revulsively upon the deeper-seated parts, and is habitually used to relieve internal congestions and diminish secretions, as in *chronic bronchitis* and *chronic pulmonary tuberculosis*. In chronic and in subacute *pleurisy* its counter-irritant action is resorted to for promoting absorption of the effusion. In these several affections it also, if applied in a plaster of proper dimensions, gives to the chest a greatly-needed mechanical support during the act of coughing. Some obstinate cases of *sciatica* have been cured by enveloping the buttock and thigh in a Burgundy pitch plaster, and leaving it permanently in place. In like manner, this plaster has been used to relieve chronic *diarrhœa* following dysentery, etc., but this cannot conveniently be done when the abdomen is prominent or flaccid.

Before applying a plaster of this sort to a hairy skin the hair should be shaved off, and in removing the plaster from such a part it should first be softened by passing lightly over its free surface a bottle of hot water or a warm flat-iron. The portion of pitch which still adheres may be partially removed by pressing upon it a linen or muslin rag, to which the adhesive material will cling rather than to the skin itself, and the remainder may be washed off with warm alcohol.

PIX CANADENSIS, U. S.—CANADA PITCH.

Hemlock pitch, E.; *Poix de Canada*, Fr.; *Canadisches Pech*, G.

The prepared resinous exudation from *Abies* (*Pinus*, *Liné*, *Picea*, *Link*, *Tsuga*, *Carrière*) *canadensis*, *Michaux*. Bentley and Trimen, *Med. Plants*, 264.

Nat. Ord.—Coniferae.

Origin.—The *hemlock spruce* is a common forest tree of Canada and the Northern United States, but is more rare farther south, where it grows principally in the Alleghanies. It attains a height of 60 or 80 feet (18–24 M.), has horizontal branches, the young ones drooping; has flat, obtuse, somewhat denticulate, and on the lower surface glaucous, leaves, and elliptic-ovate cones about an inch (25 Mm.) in length. The wood is light, coarse-grained, and less valuable for boards than that of other pines. The bark is very astringent, and by treatment with water furnishes an extract rich in tannin, and is largely employed in tanning under the name of *extract of hemlock-bark*. By distilling the branches with water a volatile oil is obtained, which is sold as *oil of spruce* or *oil of hemlock*; 8 pounds of the boughs yield about 1 ounce of oil (Stearns, 1858).

Collection.—According to Stearns, there are two methods of collecting Canada pitch, one of which consists in cutting cup-like incisions into the living tree and removing the soft oleoresin as it exudes; the other and most common one is to remove the wood and bark around the knobs or knots of the felled trees, which are rich in resin; these being placed in water in a large kettle, the resin is boiled out, and rising upon the top is skimmed off, and further purified by remelting and straining.

Description.—Canada pitch is found in the market in opaque reddish-brown masses, which gradually become translucent on the surface. It is brittle at the ordinary temperature, but usually takes the form of the vessel in which it is kept; it is of a somewhat

lighter color internally, breaks with a shallow conchoidal and glossy fracture, is softened by the heat of the hand, and has a weak somewhat terebinthinate odor.

Constituents.—It is composed of one or more resins and of a minute quantity of volatile oil, which have not yet been examined.

Adulteration.—Stearns states that Canada pitch is often adulterated by the collectors with common rosin to the extent of 70 per cent. Such an addition must render it harder and less fusible, but no test is known by which to determine the sophistication.

Off. Prep.—Emplast. picis canadensis, U. S.

Medical Action and Uses.—Canada pitch is almost identical with Burgundy pitch in its action and uses, but owing to its greater softness is less convenient for making plasters. Its volatile oil, known as oil of spruce and oil of hemlock, is said to have been employed to produce abortion. There is no reason for attributing to it a specific action on the uterine system.

PIX LIQUIDA, U. S., Br., P. G.—TAR.

Resina empyreumatica liquida.—Goudron, Goudron végétal, Fr.; Theer, G.

An empyreumatic oleoresin obtained by destructive distillation from the wood of *Pinus palustris*, Miller, and of other species of *Pinus*. Bentley and Trimen, *Med. Plants*, 258.

Nat. Ord.—Coniferæ.

Origin.—The principal species used for the production of tar are *Pinus palustris*, Miller, *P. Taeda*, Linné, *P. rigida*, Miller, which grow in North America, and *P. sylvestris*, Linné, and *Larix sibirica*, Ledebour, indigenous to Northern Europe. (See TEREBINTHINA.) Sufficient tar is produced in the United States to supply the domestic market and leave a portion for exportation. 60,393 barrels of tar and pitch were exported in 1882.

Preparation.—Pine wood which is unfit for use as timber is usually employed. It is cut into billets of suitable size, which are arranged into large conical stacks, or, as is sometimes the case in Europe, are closely packed in clay furnaces of a similar shape. The stacks or piles are covered with a layer of earth and ignited above, and the draft is regulated so as to sustain a slow combustion without flame. The tarry products, as they are formed, gradually descend and collect in a cavity or ditch at the base of the pile, from which they are transferred into barrels. The process is one of destructive distillation, in which, however, the pyroligneous acid and volatile oil of the wood are lost. These products may likewise be saved by the use of furnaces or stills, in which the distillation may be carried on in the same manner as in the stacks; but the charcoal obtained is said to be inferior to that made in the ordinary way. The tar obtained by slow combustion as described above is largely employed in the arts for various purposes, for some of which the tar resulting in the preparation of pyroligneous acid cannot be substituted.

Description.—Tar is a thick, viscid, semi-fluid mass, heavier than water, of a deep blackish-brown color, transparent in thin layers if free from water, and has an unpleasant empyreumatic odor and a sharp and bitter taste. On standing, it usually separates a granular crystalline matter consisting of *pyrocatechin*, and often assumes the consistence of thick honey. It has an acid reaction, which, together with a light-brown color and sharp bitterish taste, is imparted to water agitated with it. On the application of heat, water and acetic acid distil over, together with a yellow volatile oil (see p. 19). Tar is soluble in alcohol, ether, chloroform, fixed and volatile oils, and caustic alkalies. The aqueous infusion of tar is colored transiently green by ferric chloride, due to the presence of pyrocatechin, and with lime-water acquires permanently a brown-red color.

Constituents.—Tar is of a very complex composition, which varies with the kind of wood, the amount of resins present therein, and the care with which it has been prepared. It contains *acetic acid*, *acetone* (page 11), *methyl alcohol* (page 150), *mesit*, $C_6H_{12}O_2$, *toluol*, C_7H_8 , *xylol*, C_8H_{10} , *cumol*, C_9H_{12} , *methol*, C_9H_{12} ; likewise *phenol*, C_6H_5O (see p. 39), *cresol*, C_7H_8O (see p. 42), *creasote* (see page 513), *paraffin*, *naphthalin* (page 1011), *pyrene*, $C_{16}H_{10}$, *chrysene*, $C_{18}H_{12}$, *retene*, $C_{18}H_{18}$, and others. Of the compounds mentioned, the first series up to methol pass over with the light tar oil, which also contains Reichenbach's *empion*, a very light oily product of low boiling-point. The heavy tar oil contains the other compounds named, and in addition *cedrret*, *kapnomor*, *picamar*, and *pittakal*, which names were introduced by Reichenbach to designate various substances not yet obtained in a pure state. After distilling from tar the light and most of the heavy oil a substance is left behind which is still recognized in some pharmacopœias as

PIX NAVALIS, s. *Pice nigra*, s. *solida*, s. *Resina pini empyreumatica*.—Pitch, Black pitch, *E.*; Poix noire, *Fr.*; Schwarzes Pech, Schiffspech, *G.*—It is a black, resinous, brittle mass, which becomes soft when held in the hand, and has the odor of tar.

Allied Drug.—**PIX BETULÆ**, s. **BETULINUM**, *Oleum betulæ empyreumaticum*, *Oleum rusci*.—Birch tar, *E.*; Huile russe, Huile de bouleau, *Fr.*; Birkentheer, Birkenöl, *G.*—It is prepared in Russia from the wood and bark of *Betula alba*, *Linnaë*, and is also known in commerce under the name of *dagget* or *degutt*. It resembles wood-tar in appearance, but remains liquid and has a peculiar penetrating odor, like that of Russia leather, in the manufacture of which it is used. It was partly examined by Sobrero (1842), who obtained from it a yellowish volatile oil, $C_{10}H_{16}$, of an agreeable odor, like that of birch-bark, and boiling at $156^{\circ} C.$ ($312.8^{\circ} F.$). (See also page 317.)

Pharmaceutical Products.—**SACCHARATED TAR**, tar purified by dissolving in warm alcohol, straining, and evaporating, 4 parts, sugar 96 parts; mix (Roussin, 1871).

AQUA PICIS, s. **PICEA**, *P. G.*; **INFUSUM PICIS LIQUIDÆ**, *U. S.* 1870.—Tar-water, Infusion of tar, *E.*; Eau de goudron, *Fr.*; Theerwasser, *G.*—Mix well tar 1 part with powdered pumice-stone 3 parts, and agitate the mixture, which may be kept on hand, for 5 minutes with water 10 parts. Tar-water is to be made fresh when wanted.—*P. G.*

Prepared in this manner, the water is enabled to exert its solvent action upon all the constituents of tar. Magnesia is unsuited for dividing the tar, owing to the formation of soluble salts. Magnes-Lahens (1876) pulverized the tar by mixing it with twice its weight of inert sawdust; 27 Gm. of this mixture will give with 1 liter of water a saturated solution containing 6 Gm. of extract. The large quantity of resinous and oily principles present in tar interferes with the solvent action of water; hence an excess of tar must be used, the first infusion being strongly acid, and, according to the French Codex, is rejected. Lefort (1868) determined the amount taken up by hot water to be 2 Gm. to the liter.

GLYCERITUM PICIS LIQUIDÆ, *U. S.* 1870.—Glycerite (glycerol) of tar, *E.*; Glycérolé de goudron, *Fr.*; Theerglycerol, *G.*—Triturate tar 1 troyounce with magnesium carbonate 2 troyounces; afterward with portions of a mixture composed of glycerin 4 fluidounces, alcohol 2 fluidounces, and water 10 fluidounces; express the liquid, put the residue into a percolator, and displace first with the expressed liquid, and afterward with water, until 18 fluidounces of percolate are obtained. This is essentially the formula proposed by J. B. Moore in 1869. The glycerite is of a rich reddish-brown color, and perfectly transparent when recently prepared, but gradually deposits blackish resinous matter, which should be filtered off.

TINCTURA PICIS BETULÆ, **TINCTURA RUSCI**, Tincture of birch-tar. Dissolve birch-tar 1 part in alcohol 10 parts, and filter.

Off. Prep.—**Syrupus picis liquidæ**, *U. S.*; **Unguentum picis liquidæ**, *U. S.*, *Br.*

Physiological Action.—Tar is hostile to insects, and is used successfully for destroying the *Acarus scabiei*. Applied to the skin where it is delicate, it is apt to cause a sense of heat and irritation, and occasionally even vesication, with an erythematous redness. Internally and in small doses it acts as a general stimulant, although when freely given it tends to impair the appetite. In larger doses it occasions oppression, nausea, vomiting, colic, and diarrhœa, with frequency of the pulse. In excessive quantities, besides these effects it may give rise to headache, a sense of intoxication and general depression, with irritation of the kidneys, and the secretion of high-colored urine smelling strongly of tar and giving a deposit on the addition of nitric acid. This deposit is distinguished from albumen by its solubility in alcohol or ether. Cases are reported of fatal poisoning by tar. Tar-water in small doses is said to quicken the pulse and augment the secretion of the skin and kidneys. The vapor of tar, when inhaled, increases the normal bronchial secretion, but diminishes that which depends upon an atonic condition of the bronchia. Applied to the skin pure or in an ointment, and especially in the treatment of skin diseases, it is very apt to occasion nausea and vomiting or diarrhœa; the discharges from the stomach and bowels have the characteristic odor of tar, and the urine the peculiar color and smell caused by tar taken internally.

Medical Uses.—Anciently, tar was used as a dressing for wounds and sores and various cutaneous eruptions in man and beast, and was administered internally as a remedy for chronic pulmonary complaints. These are the affections in which even now it is principally used. Tar-water is prepared by stirring 1 part of tar with 10 parts of pure water, and allowing them to stand for several days, and then decanting the impregnated water. It has been used with the greatest advantage in *chronic bronchitis* and in many cases of pulmonary *phthisis*, lessening the expectoration, diminishing the oppression and pain in the chest, and soothing the cough, without increasing the thirst or impairing the digestion. But when hectic symptoms are prominent it is seldom tolerated. This is true even of the treatment of these diseases by the inhalation of tar vapors, which in the more torpid cases is sometimes remarkably beneficial. The best mode of using tar vapors is the following: In a cup placed in a small water-bath over a common night-lamp mix some tar with about a twenty-fourth part of its weight of carbonate of potassium, in

order to neutralize the pyroligneous acid which may be present and which would irritate the lungs. The vapors should be extricated very slowly at first, so as moderately to charge with them the air of the chamber which the patient chiefly inhabits, and afterward they may be generated more freely. Quite as beneficial, and more convenient and agreeable, is the inhalation of tar-water, and even of wine of tar, from a steam atomizer.

Of other internal uses of tar may be mentioned that of tar pills for the relief of *constipation*, the use of tar-water by the mouth and by injection in chronic *vesical catarrh*, *gleet*, *leucorrhœa*, etc.

The ancient use of tar in the treatment of *scabies* is sometimes still resorted to, but it is less certain than other methods of curing it permanently, and it involves the ruin of the patient's body- and bed-linen. In *scaly eruptions* its efficacy is much more unequivocal, but the same objection to it exists as in the case of the disease just mentioned. Moreover, *lepra* and *psoriasis* generally get well under the use of arsenic alone. If this falls short of its purpose, tar may be employed in addition. For its efficient use it is necessary that the scales upon the skin should first be removed by a warm bath; after which the tar or its ointment should in small quantity be rubbed into the patches of the eruption with a brush, and the patient rolled in a blanket and allowed to remain quiet for five or six hours, when the excess of the application can be removed with cloths and the ordinary clothing resumed. In some cases of inveterate *eczema*, when the skin has become dry, rough, and thick, tar ointment or oil of tar is a most efficient remedy, provided that its strength be duly proportioned to the sensibility of the skin. It is also useful in *herpes circinatus* and in *prurigo*.

Tar has long been employed by the vulgar for *excoriations*, *boils*, *scorbutic sores*, and *unhealthy ulcers* generally. Of late it has been extensively used in the form of oakum as a dressing for such lesions, especially in hospitals. It seems especially adapted to burns which suppurate copiously. It corrects the fetor of such sores. The oakum is applied after being moistened with water, and is covered with an impermeable tissue. Tar and tar-water have been applied to *mercurial ulcers* of the mouth and throat, and the former is an excellent application to *fissured nipples* and *hæmorrhoids*. Finally, the fumes of tar are commonly used to deodorize and purify vessels, rooms, etc. tainted with *foul smells* or supposed to be infected with morbid poisons. They have also been employed advantageously in the treatment of senile *gangrene* (Post, *Trans. New York State Med. Soc.*, 1877, p. 246).

Tar may be given mixed with milk or beer, or else in pills. From 30 grains to $\frac{1}{2}$ ounce (Gm. 2-16) may be taken daily. The glycerite of tar is a convenient form of the medicine. Tar-water may be taken to the extent of a pint or two daily.

PLANTAGO.—PLANTAIN.

Rib-grass, *Ribwort*, *Ripple-grass*, E.; *Plantain*, Fr.; *Wegerich*, G.

Plantago lanceolata, Linné, and *Pl. major*, Linné.

Nat. Ord.—Plantaginaceæ.

Description.—These are acaulescent perennials, with short oblique rhizomes. The first-named species has lanceolate, obscurely toothed, more or less hairy and about five-ribbed leaves, and a deeply-furrowed scape bearing a dense ovate spike. The second species has broadly ovate or elliptic, somewhat toothed, about seven-ribbed, nearly smooth, petiolate leaves and a terete scape, bearing a cylindrical elongated spike. The flowers are small, have a dry membranaceous four-lobed corolla with four stamens, and produce small capsules containing two, or in the second species about ten, peltate brown seeds. The plants are indigenous to Europe, but now grow along roadsides and in fields in most temperate countries. They are inodorous and have a somewhat astringent, saline, and bitterish taste.

Constituents.—The analyses by Sprengel, Koller, Bley, and Schlesinger showed the presence of a bitter principle, albumen, sugar, resin, and various salts. Runge (1828) stated that, in common with various Umbelliferae and Compositæ, they contain *viridinic acid*, which forms with ammonia a yellow compound turning green on exposure to air; it belongs doubtless to the tannins.

Allied Plants.—*PLANTAGO VIRGINICA*, Linné. White plantain. It is common in sandy fields of the United States. The radical leaves are white-pubescent, obovate or spatulate, about 2 inches (5 Cm.) long; the short scape bears a dense cylindrical spike; the capsules are two-seeded. The plant agrees with the preceding ones in taste.

PLANTAGO PSYLLIUM, Linné. This annual plant is indigenous to the basin of the Mediterra-

nean. The seeds are employed and are known as fleaseed, *E.*; graines de puces, *Fr.*; Flohsamen, *G.* They are about $\frac{1}{2}$ inch (2 Mm.) long, boat-shaped, dark red-brown, and glossy, upon the convex back with a lighter colored line, the hilum located in a broad groove upon the lower side. The seeds of *Plantago arenaria*, *Waldstein et Kitabel*, are somewhat smaller, black and less glossy; those of *Plantago cynops*, *Linne*, are somewhat larger and lighter brown. The epithelial layer of these seeds yields much mucilage; this is also obtained from

SPOGEI-SEEDS, known in India as *ispaghul*. They are about $\frac{1}{2}$ inch (3 Mm.) long, pinkish-gray, and on the convex side marked with a brown-yellow spot. They are obtained from *Plantago Ispaghula*, *Rochburgh*, which is regarded as a cultivated variety of *P. decumbens*, *Forsk.*, indigenous to Northern Africa. (See Bentley and Trimen, *Med. Plants*, 211.) The seeds of several other species are likewise mucilaginous.

History and Uses.—The several species of plantain appear to have enjoyed the undeserved reputation of being remedies for divers diseases, including malignant ulcers, defluxions and mortifications, hæmorrhages, intermittent fever, etc. They owe whatever virtues they possess to their bitter and astringent constituents. In Europe they are still used for the same purposes as of old, and their fresh leaves are applied to wounds and inflammations of the skin. Quite recently (1883) Prof. Quinlan, observing a cottager arresting hæmorrhage by the application of the chewed leaves of *P. lanceolata*, "satisfied himself as to the hæmostatic power of the plant when applied to bleeding surfaces either in the chewed form or in that of the dried leaves" (*Practitioner*, xxx. 49).

PSYLLIUM (*Plantago psyllium*), *fleawort*, was anciently used in the treatment of ulcers, and was reckoned a cooling and astringent medicine. In Asia and in Southern Europe the mucilage derived from its seeds is used very much as the mucilages of quince, flaxseed, and slippery elm are applied to palliate external and also internal irritations. It has been employed with advantage to relieve habitual constipation by swallowing a tablespoonful of the seeds in half a tumbler of water before the principal meal. But it soon loses its original effect.

PLATINUM.—PLATINUM.

Platine, Or blanc, *Fr.*; *Platin*, *G.*

Symbol Pt. Atomicity bivalent and quadrivalent. Atomic weight 194.4.

Origin and Preparation.—This metal was apparently observed as early as the sixteenth century, but was more fully described and investigated after the middle of the eighteenth century by Watson, Scheffer, Lewis, Bergman, and others. It is found pure and in combination with palladium, rhodium, osmium, iridium, and other metals in California, in various parts of South America, in the Ural Mountains and other parts of Europe, and in Asia and Africa. It is often met with in auriferous sand, and occasionally in lead, iron, and other ores. The ore is treated with strong hydrochloric acid, well washed by elutriation, the residue treated with nitromuriatic acid, the acid solution evaporated, redissolved in water, and precipitated with ammonium chloride; on igniting the resulting ammonio-platinic chloride, platinum is obtained in a spongy condition.

Properties.—Spongy platinum is gray, soft, and porous, and fusible only by the aid of the oxyhydrogen blowpipe. The metal is of a silver-white color and metallic lustre, is soft like copper, possesses considerable malleability and ductility, and at a white heat may be forged. Platinum resists the action of most chemicals except mixtures of nitric with hydrochloric or hydrobromic acid, but at a high temperature it is readily attacked by most elements. With oxygen it forms a protoxide, PtO , and a binoxide, PtO_2 , which are reduced to the metal at a red heat. The platinous salts are brown, red, or colorless; the platonic salts have a yellow or brown color. The following compounds have been used:

PLATINIC CHLORIDUM.—Platinic chloride, *E.*; Perchlorure de platine, *Fr.*; Platinechlorid, *G.* $\text{PtCl}_4 \cdot 5\text{H}_2\text{O}$; molecular weight 426.—It is prepared by dissolving 3 parts of platinum in a mixture of 16 parts of hydrochloric and 7 parts of nitric acid, evaporating the solution nearly to dryness, redissolving in hydrochloric acid, heating to expel the nitric acid, and evaporating at a moderate heat to dryness, when a red crystalline mass is left, which may be obtained from water in handsome red crystals containing 46 per cent. of platinum. When heated to 100°C . these lose $4\text{H}_2\text{O} = 16.9$ per cent., and turn brown. If the salt is permitted to crystallize in the presence of free hydrochloric acid, brownish-red needles are obtained which have the composition $\text{PtCl}_4 \cdot 2\text{HCl} \cdot 6\text{H}_2\text{O}$, and contain 38 per cent. of platinum. This is the compound usually met with in commerce. Heated to above 110°C ., it parts with hydrochloric acid and chlorine, and near 225°C . (437°F .) dark-brown platinous chloride is left. Platinum chloride dissolves readily in alcohol and

water, yielding reddish-yellow liquids which precipitate the chlorides of potassium and of ammonium.

PLATINI ET SODII CHLORIDUM. Platino-chloride of sodium. Chloride of sodium and platinum. The double salt, $2\text{NaCl}.\text{Pt}(\text{Cl}_4.6\text{H}_2\text{O})$, crystallizes in light-red prisms, and is freely soluble in water and alcohol. For medicinal purposes a preparation containing an excess of the sodium salt is used, made by dissolving 3 parts of platinic chloride and 5 parts of sodium chloride in water, and evaporating to dryness, stirring continually. It is an orange-yellow powder having a saline and metallic taste.

PLATINI IODIDUM, Platinic iodide, PtI_4 . A solution of platinic chloride is mixed with a solution of an equivalent quantity of potassium iodide, the deep-red mixture nearly neutralized with potassium carbonate, and digested for an hour. The precipitate, after washing and drying, is a brown-black amorphous and tasteless powder, insoluble in water, but soluble in carbonate and iodide of potassium with a pale-red color.

PLATINI ET POTASSII CYANIDUM. Platino-cyanide of potassium, $2\text{KCN}.\text{Pt}(\text{CN})_2.3\text{H}_2\text{O}$. It is best prepared, according to Meillet, by mixing rather concentrated solutions of 1 part exsiccated platinic chloride and 2 parts potassium cyanide, and heating the mixture until the precipitate is redissolved; carbonate of ammonium and nitrogen are given off, and on cooling the double salt crystallizes. It forms long needles and prisms, having in different positions a yellow or bright-blue color, and when exposed to the air become opaque and rose-red. The salt is freely soluble in hot water, and its solution precipitates cupric salts greenish-blue, mercurous nitrate bright-blue, and ferrous salts bluish-white.

Physiological Action and Medical Uses.—There is very little to be added to the statements that were made by Höfer in 1840 respecting the compounds of this metal. He found that its chlorides were as poisonous as the chlorides of gold and mercury—the perchloride in 1-grain doses, the chloroplatinate of sodium in the dose of 2 grains. The perchloride in strong solution irritates the skin and occasions a slight eruption upon it. Internally, in small doses, it irritates the stomach, causes headache, and gradually modifies the blood and the secretions. The chloroplatinate of sodium, on the other hand, is not a local irritant, and its internal action is not as distinct as that of the perchloride of platinum. According to Bryk, perchloride of platinum applied to the skin produces a thick, yellowish-white, dry eschar, surrounded by intense injection and even extravasation. Given to rabbits in the dose of 30 grains, it caused convulsions and death. The experiments of Kebler (1878) led him to conclude—1. That it deprives frogs of the power of voluntary motion by acting on the motor centres, but at the same time excites spasmodic movements resembling those made by volition. The irritability of the paralyzed muscles is sensibly diminished, but not lost until death. The heart-muscles are unaffected. 2. In mammals it produces vascular paralysis, whose cause is in an altered state of the peripheral extremities of the nerves. The vomiting, diarrhoea, sometimes with bloody stools, the hyperæmia of the abdominal organs, the ecchymoses of the stomach, intestines, and bladder, were regarded as effects of the same cause, and in part also the phenomena displayed by the central nervous organs. (Compare Hofmeister, “Ueber die physiologische Wirkung der Platinbasen,” *Archiv f. exp. Pathol. u. Pharmacol.*, xvi. 393.)

According to Höfer, chloride of platinum is an efficient remedy for *syphilis*, and especially for its inveterate constitutional forms, and chloroplatinate of sodium is more suitable in the primary stages of the disease. The former has been described as analogous in its effects to the chlorides of gold and mercury. The dose of it is stated to be from $\frac{1}{4}$ to $\frac{1}{2}$ grain (Gm. 0.008–0.03) several times a day in mucilage or pill. A solution of 30 grains in 8 ounces (Gm. 2 in Gm. 250) of water has been used as an injection in *leucorrhœa* and *gleet*, and a liniment containing 2 grains to the ounce (Gm. 0.12 to Gm. 32) of olive oil or lard has been applied to indolent *ulcers*.

PLUMBI ACETAS, U. S., Br.—ACETATE OF LEAD.

Plumbum acetium, P. G.; *Acetas plumbicus*, *Saccharum saturni*.—Sugar of lead, E.; *Acétate de plomb*, (*Sucre*) *de saturne*, Fr.; *Essigsäures Bleioxyd*, *Bleizucker*, G.

Formula $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2.3\text{H}_2\text{O}$. Molecular weight 378.5.

Preparation.—Take of Oxide of Lead, in fine powder, 24 ounces; Acetic Acid 2 pints or a sufficiency; Distilled Water 1 pint. Mix the acetic acid and the water, add the oxide of lead, and dissolve with the aid of a gentle heat. Filter, evaporate till a pellicle forms, and set aside to crystallize, first adding a little acetic acid should the fluid

not have a distinctly acid reaction. Drain, and dry the crystals on filtering-paper without heat.—*Br.*

The process described is frequently followed on a large scale. Sometimes, however, metallic lead is dissolved in acetic acid, which requires to be done in the presence of air, since the metal is unable to displace the hydrogen of the acid. Plates of lead are placed endwise in open vessels containing acetic acid, one-half of their length projecting above the liquid, and as fast as the metal under these conditions is oxidized by the oxygen of the air, it is dissolved, so that the formation of the salt in both cases is the result of the action between plumbic oxide and acetic acid, water being formed at the same time; $\text{PbO} + 2\text{C}_2\text{H}_4\text{O}_2$ yields $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 + \text{H}_2\text{O}$. To obtain handsome and well-defined crystals the solution must have a very distinct acid reaction: if it is permitted to become neutral or faintly acid, a portion of the salt forms small granular crystals agglomerated into soft cauliflower-like masses, containing perhaps a basic lead compound.

For uses in the arts large quantities of impure acetate of lead are prepared from wood-vinegar, and vary in color from various shades of brown to pale-red and white.

Properties.—Pure acetate of lead crystallizes in colorless, glossy, transparent or translucent prisms, which are often tabular and have an acetous odor and a sweet astringent

FIG. 222.

Crystal of Lead Acetate.

and metallic taste. It is slightly efflorescent in the air, and on continued exposure is superficially converted into carbonate of lead. It fuses at 75.5°C . (168°F .), and congeals on cooling slowly to a radiating crystalline mass. At 100°C . (212°F .) it rapidly loses water and a portion of the acid, and at a higher temperature is decomposed, giving off acetic acid and acetone. It contains 14.2 per cent. of water of crystallization, which it loses over sulphuric acid and by the action of absolute alcohol, crystallizing from this liquid in an anhydrous condition; but when dissolved in hot stronger alcohol the salt crystallizes on

cooling with $2\text{H}_2\text{O}$. It dissolves at 15°C . (59°F .) in $1\frac{1}{2}$ parts, at 40°C . (104°F .) in 1 part, and at the boiling-point in $\frac{1}{2}$ part of water. The solution has a slight acid reaction, and if concentrated and mixed with strong alcohol gradually separates a portion of the salt in crystals. It dissolves also in about 1 part of boiling and in 8 parts of cold alcohol, and is precipitated from this solution as a crystalline powder on the addition of ether. The aqueous solution acquires a red color on the addition of a little dilute solution of ferric chloride, and is precipitated by the various reagents for lead salt (see below). On heating the salt in the flame of the blowpipe upon charcoal, globules of metallic lead are obtained, surrounded by a reddish-yellow incrustation. The salt is decomposed by the mineral and many organic acids, acetic acid being liberated.

Tests.—Acetate of lead should yield a clear solution with distilled water. A slight turbidity resulting from the presence of a little carbonate must disappear on the addition of a small quantity of acetic acid. Perfect solubility indicates the absence of sulphate and notable quantities of chloride. The aqueous solution, completely precipitated by sulphuretted hydrogen, should yield a filtrate which is not precipitated by ammonia and sulphhydrate of ammonium (zinc, etc.) or oxalic acid (calcium, barium), and it does not leave any fixed residue on being evaporated to dryness (alkalies). Small quantities of copper would be indicated by the blue color of the filtrate obtained after precipitating the solution of the salt with an excess of ammonia. Ferrocyanide of potassium should yield a white precipitate (absence of copper, iron, etc.), and on treating the salt with sulphuric acid in the presence of a crystal of ferrous sulphate a black color should not be produced (nitrate). "38 grains of acetate of lead dissolved in water require for complete precipitation 200 grain-measures of the volumetric solution of oxalic acid."—*Br.*

PLUMBUM ACETICUM CRUDUM. *P. G.* The solution of the salt in 3 parts of distilled water may be opalescent, but should yield a white (not a colored) precipitate with potassium ferrocyanide.

Off. Prep.—*Liq. plumbi subacetatis*, *U. S.*, *Br.*; *Pilula plumbi e. opio*, *Suppos. plumbi comp.*, *Unguent. plumbi acet.*, *Br.*

Physiological Action.—*On Animals:* Given to dogs in large but not immediately poisonous doses, acetate of lead occasions signs of pain, with vomiting and purging, and sooner or later death; after which the gastric mucous membrane is injected with venous blood and covered with thick mucus. If the dose has not been sufficient to prove fatal within a few days, paralysis occurs, of the hinder and then of the fore limbs, with embarrassed and spasmodic breathing, signs of extreme distress, and death by exhaustion. Injected into the veins, it destroys life, with signs of pulmonary congestion and feeble

action of the heart, the right cavities of which, with the lungs, are after death found distended with blood. After such poisoning lead may be found in the portal blood, the liver, the spleen, the urine, etc., but most of all in the bones, according to some observers—in the spleen, according to others. In his experiments on the slow poisoning of rabbits and guinea-pigs Maier found fatty degeneration of the gastro-intestinal glands, dilatation of the arteries, venous congestion, proliferation of the submucous connective tissue, and sclerous degeneration of the submucous and mesenteric ganglionic apparatus. These lesions he associates with saturnine colic and the emaciation of the animals experimented upon (*Virchow's Arch.*, xc. 455). Popow directed his attention more particularly to the alterations produced by lead in the spinal marrow. He found that the earliest local changes consisted of congestion of the veins of the pia mater and scattered exudations of blood. The gray substance of the cord was also hyperæmic, and presented bloody extravasations. The nerve-cells of the gray substance were in all cases altered. This appeared to be uniformly the starting-point of the lesion even when the white substance was more or less involved. Hence, concludes Popow, the spasms, anæsthesia, etc. of lead-poisoning must all be referred to their primary origin in the spinal centres, and not to any lesion of the nerve-trunks (*Ibid.*, xciii. 362). Esculent plants nourished by water from lead-factories become poisonous, and animals that breathe the air of such places are apt to be affected with convulsions or paralysis. According to Rutherford, acetate of lead seems to be a direct hepatic depressant.

On Man: Locally applied, a solution of acetate of lead blanches and corrugates the skin; hence it is said to be astringent. It is shown to be a cardiac sedative by its power of reducing the pulse-rate. An overdose, besides causing a sense of constriction and sweetness in the mouth, soon excites pain in the abdomen, with vomiting and diarrhœa, which is sometimes bloody; the limbs tremble and are affected with slight spasms, or even convulsions. Sometimes there is a giddiness like that of intoxication. There may be fever, hurried respiration, and scanty urine. Recovery from acute lead-poisoning is the rule, however severe the primary symptoms may be. Doses of from 2 to 8 drachms of the acetate have been taken without injury, but sometimes also a protracted derangement of the digestion is induced, which ultimately proves fatal. One case is recorded in which a drunken man took 3 ounces of this salt, and, although not treated for 24 hours, recovered (Luck). A singular case of death by acetate of lead was that of a woman who while using this salt as a vaginal injection was seized with peritonitis, of which she died. A precipitate of sulphide of lead was found on the surface of the peritoneum (*Amer. Jour. of Med. Sci.*, Oct. 1880, p. 577).

The long-continued use of medicinal doses of acetate of lead produces a metallic taste in the mouth, tenderness and swelling of the gums, and often a bluish line where they are attached to the incisor teeth, slowness and feebleness of the pulse, colic, a sense of constriction of the trunk, and some numbness of the hands and feet. To these symptoms may be added fetid breath, loosening of the teeth, blackened feces, neuralgic pains in the legs first, and then in the arms. It may be remarked, however, that these effects must be very rare indeed, since hardly any of the physicians who prescribe the medicine habitually have witnessed them. The most common evidence of chronic lead-poisoning is a peculiar paralysis of the extensor muscles (not of the supinators) of the hands first, and subsequently of the legs. It has been produced by hair-dyes and face-powders, by lotions, ointments, plasters, etc., containing lead; in compositors by handling type; by the use of snuff, wine, cider, beer, water, flour, and even air, impregnated with lead particles, as in freshly-painted rooms; by the use of food put up in leaden coverings or cooked in leaden utensils, and by chewing tobacco kept in leaden wrappers. Among those who work in lead in its manufacture or in its use as a pigment, or who drink liquors impregnated with it, the most usual effect is the so-called painter's colic, which appears to be a neuralgia with spasmodic contraction of the intestines. The investigations of Friedländer into the nature of the lesions causing lead-paralysis led him to conclude that lead affects the structure of muscles as well as their function, causing wasting of the nuclei of their cells and an atrophy of their fibres. Next in order, and probably as an effect, a degeneration of the nerves of the muscles takes place. Hence a paralysis is produced which is essentially peripheral, and which leads to the rapid atrophy of the affected muscles. This opinion is opposed to that of Popow given above.

Besides the paralysis of the extensor muscles, which is apt to result in their atrophy and a corresponding rigid contraction of the opposing flexors, other nervous symptoms arise from the same poison, and delirium, convulsion, or coma gives characteristic features to the attack. The delirium varies from mere wandering of the mind to maniacal vio-

lence; the convulsive attacks are generally epileptiform, and coma may either follow convulsion or occur independently of it. After death the only apparent lesion may be hypertrophy of the brain.

In many cases of chronic lead-poisoning albuminuria has been observed, and lead detected in the bile and urine; in pregnancy the death of the fœtus and abortion are very apt to occur. Where paralysis has long continued the muscles and the nerves that supply them are atrophied, and sulphuret of lead has been extracted from the spinal cord after death.

Although such effects are occasionally traceable to the influence of the acetate of lead, they are in the great majority of instances due to the toxic influence of other compounds of the metal; and when the vehicle is drinking-water its effects are owing to the presence of oxide and carbonate of lead diffused in water which does not contain enough sulphuric acid, and possibly of some other substances, to precipitate them. Hence the purer the water conveyed through leaden pipes or contained in leaden cisterns, the greater is the risk of its contamination. It has been suggested that those who, while they use water impregnated with lead, partake of salt freely, are more liable than others to be poisoned, since the chloride of sodium favors the production of a soluble and therefore readily-absorbed salt of lead.

The conclusions of Harnack's experiments on the mode of action of lead salts are important enough to be introduced here: "1. Lead colic as a symptom of chronic lead-poisoning is due to an irritation of the intestinal ganglia by the lead, and the consecutive disorder of the intestinal functions. In man the usual obstinate constipation is owing to general spasm of the intestine, but in the lower animals, on the other hand, there are increased peristaltic action and diarrhœa. The spasm of the intestine expels the blood from its vessels, causing plethora in other organs, while arterial tension is observed and slowing of the pulse. The pain is caused by intestinal spasm, and in part also by the consequent irritation of the peritoneum. The retraction and rigidity of the abdomen result from a reflex contraction of the muscles of its walls. [The more palpable explanation is more probable—viz. that the shrinking of the bulk of the contents of the abdomen involves the sinking in of its movable walls.] 2. The symptoms of lead-paralysis are due to the action of lead on the striated muscles. The fact that in the beginning the muscles do not lose their excitability, but only are rapidly exhausted, makes intelligible why muscles paralyzed with lead are not tetanized by the induced current, but are still competent to manifest their reaction occasionally. 3. Neuralgia of the joints from lead is due to the irritation of certain motor nerve-centres by the metal. 4. Cerebral symptoms of chronic lead-poisoning are due to modifications produced by it in various parts of the central organs of the nervous system. They are mostly of an irritative nature, and do not usually involve until late the centres situated in the brain and medulla oblongata. Experiments upon animals throw no light upon the occurrence of anæsthesia, amaurosis, etc. from lead." The observations of Friedländer are fully in accord with these conclusions (*Virchow's Archiv*, lxxv. 24), as are those of Dejerine, and so is the report of a fatal case by Zunker (*Zeitschrift f. klin. Med.*, i. 496), who found a high degree of degenerative neuritis—greatest, however, at the periphery and diminishing toward the origin of the nerves—a marked degeneration and atrophy of the affected muscles, and an irregularly distributed atrophy of the gray substance of the cord. On the whole, he concludes that in lead-palsy the nerves and muscles alone are at first affected, and that only in course of time do lesions arise in the spinal cord and other organs. Among these lesions is degeneration of the arteries, causing in the eye amblyopia, in the kidneys chronic sclerotic nephritis, and in the joints arthritis, which in predisposed persons assumes the characters of gout. (Compare Duckworth, *St. Bart's Hosp. Reports*, xvii. 249.)

When a *poisonous dose* of acetate of lead has been taken, sulphate of magnesium in a large quantity of water, with the addition of ipecacuanha, should be given to neutralize the poison and favor its rejection by vomiting. Afterward the solution of sulphate of magnesium should be continued, as an antidote to whatever portion of the lead salt may have reached the intestine and to cause its expulsion by purgation. If pain exists, it should be palliated by opiates, especially by the hypodermic injection of morphia. The ordinary treatment of *lead colic* consists in the methodical use of opiates and evacuants—the former hypodermically, the latter in the form of a solution of sulphate of magnesium or of sodium with tartar emetic, while large purgative enemata are repeatedly administered and large and warm emollient cataplasms are applied to the abdomen. Instead of saline cathartics, croton oil may be used. The action of purgatives may be aided, or even superseded, by that of induced electricity, which has the advantage of relieving the pain

at the same time. Alum, as elsewhere stated, is a most valuable remedy in this affection, and by some is held to be superior to purgatives.

In the more chronic forms of *lead-poisoning* the chief dependence must be placed upon iodide of potassium, which carries off the lead with the urine, and upon sulphurous baths, which remove it as it is eliminated from the skin, while means are taken to stimulate the paralyzed muscles by means of friction, massage, and, above all, by induced electricity. It is true that the use of the iodide of potassium as a means of eliminating lead from the system has been objected to on the ground that it must form an insoluble iodide of lead, and therefore only confirm the hold of the poison upon the tissues. Whether this must be the result of administering the remedy or not may be left to ingenious scientists to determine for their own satisfaction, while physicians continue to cure their patients by means which time as well as reason has approved. Meanwhile, it should be observed that under the use of the iodide of potassium in cases of lead-paralysis, lead is actually found in the urine (*Monthly Abst.*, Feb. 1881, p. 122; *Edinb. Med. Jour.*, xxviii. 651). A possible source of error in testing urine for lead by means of iodide of potassium is the fact that if the patient is taking bismuth a yellow iodide of that metal will be formed, identical in appearance with the iodide of lead (*Putnam, Boston Med. and Surg. Jour.*, Oct. 1883, p. 815). As a stimulant to the spinal centres of muscular motion strychnia is of extreme utility. The cerebral affections produced by lead are but little under the control of any medicine except opium, which is of great value in subduing delirium in the maniacal form.

Medical Uses.—*Internally*: Among internal *styptics* which act after absorption into the blood none is so general in its application or certain in its effects as acetate of lead. It is said to be more efficient in active than in passive hæmorrhages, but the rule, if it be one, is not absolute. It has repeatedly and unequivocally displayed its virtues in *hæmoptysis*, not so distinctly in *uterine hæmorrhage* connected with menstruation and with parturition, and still less conspicuously, though decidedly, in hæmorrhage from the *stomach*, *bowels*, and *kidneys*; in all of which cases ergot, the chlorides of iron, creasote and its congeners, excel it.

The sedative action of acetate of lead upon the heart, and its power of promoting coagulation of the blood, are thought to be illustrated by cures of sacculated *aneurism* alleged to have taken place under its use; and, although the evidence may not be conclusive, it is strong enough to inspire a certain degree of confidence in this plan of treatment. The same may be said of *hypertrophy of the heart*. But in the latter case the utility of the medicine is less demonstrable and more improbable.

In chronic *dysentery* and *diarrhœa* acetate of lead is one of the most valuable medicines of its class when given by the mouth and also by the rectum; and the same is true of its use in the decline of the acute form of the first-named disease. While the febrile symptoms continue it should seldom be employed. It is best administered in doses of 1 or 2 grains (Gm. 0.06–0.12) three or four times a day, associated with a grain or less of opium or 2 or 3 grains of Dover's powder. In some cases of *tympanites* due to indigestion, and of the same condition during *typhoid fever*, it has afforded relief.

The astringency it manifests in the diseases already named has been further shown in pulmonary affections with excessive secretion. It has long been in common use for diminishing the sputa in *tubercular phthisis* and *chronic bronchitis*, as well as for checking *sweats* in both diseases. In *whooping cough* with profuse bronchial secretion it has also been used. It has been recommended as the safest and best remedial agent in *pneumonia*, and particularly as superior to digitalis, tartar emetic, and veratrum; which may very well be, since these medicines are worse than useless in the disease.

In various nervous diseases, including *epilepsy*, *neuralgia*, *chorea*, and *hysteria*, it has been alleged to be curative; but this statement is without substantial foundation, except in regard to epilepsy, but that disease has seldom been treated by acetate of lead.

Externally: Acetate of lead has been less frequently employed than the subacetate as an astringent of external parts, yet it may be applied with advantage in lotions to *contusions*, *excoriations*, *sprains*, *fractures*, etc. It is more conveniently employed in collyria for *conjunctivitis*, both acute and chronic, and as an injection into the urethra in *gonorrhœa* and into the vagina in *leucorrhœa*. In chronic granular *conjunctivitis* finely-powdered acetate of lead has been applied to the mucous surface of the eyelids. A preparation which is in reality a solution of subacetate of lead has been made with acetate of lead 5 parts, litharge $3\frac{1}{2}$ parts, glycerin 20 parts. These ingredients, on being exposed to a temperature of 350° F. for some time and filtered through a hot-water funnel, furnish a clear viscid glycerole containing 120 grains of subacetate of lead to the ounce. When used, it

can be diluted with glycerin. It is stated to be peculiarly applicable to the treatment of certain forms of *chronic eczema*, especially of the lower extremities. It appears to be most useful when the affection is extensive, of a dusky hue, accompanied by much weeping, oozing, and infiltration of the skin, together with swelling of the subcutaneous tissue and a full and varicose condition of the veins. Its diligent application should be followed by careful bandaging (Duhring and Van Harlingen).

Administration.—As a styptic the *dose* of acetate of lead should be not less than 2 grains (Gm. 0.12) every hour, and generally associated with opium. As much as 5 grains (Gm. 0.30) every hour has been used successfully, and without damage, in certain cases of hæmorrhage. In diarrhœal and dysenteric affections 1 grain, with $\frac{1}{2}$ grain of opium (Gm. 0.06 with Gm. 0.03), three or four times a day, is the average dose; and for colliquative sweats 2 grains (Gm. 0.12) several hours before the usual time of appearance of the symptom.

PLUMBI CARBONAS, U. S., Br.—CARBONATE OF LEAD.

Cerussa, P. G.; *Plumbum carbonicum*, s. *hydrico-carbonicum*, *Carbonas plumbicus*.—*White lead*, E.; *Carbonate de plomb*, *Blanc de plomb*, *Céruse*, Fr.; *Bleicreiss*, *Bleicarbonat*, G.

Formula $2\text{PbCO}_3 \cdot \text{PbH}_2\text{O}_2 = \text{Pb}_3(\text{CO}_3)_2(\text{OH})_2$. Molecular weight 773.75.

Preparation.—On passing carbonic acid gas through a solution of acetate of lead, or on adding an alkaline carbonate to a solution of a neutral lead salt, a precipitate of PbCO_3 is obtained, which, as a pigment, has less *body* than the basic salt. The latter is obtained in two ways. One method, known as the *Dutch process*, is as follows: Cast sheets of lead are suspended in earthen pots containing a small quantity of vinegar or pyroligneous acid; a number of these pots are arranged in rows, alternating with layers of dung or spent tan, until a shed is filled, which is entirely covered with the same material. A warm and moist atmosphere, charged with carbonic acid, is thus produced in the shed, favorable for the oxidation of the metal and its conversion by the acetic vapors into basic acetate of lead, which is decomposed by the carbonic acid, yielding white lead and neutral acetate. The latter again unites with a fresh portion of oxide, forming basic acetate of lead, which is again acted upon by the carbonic acid; and the process continues until, in the course of a few weeks, the lead is completely covered with a thick crust of white lead, which is detached, ground with water, and washed to remove acetate of lead, and dried. Various modifications of this process have been recommended and are in use, the most important one being that largely used in Austria, where the sheet lead is suspended in wooden boxes, vapors of acetic acid, moisture, and carbonic acid gas being supplied in various ways; a number of such boxes are placed in a suitable room, where the temperature is slowly raised from about 25° to 50° C. (77° to 132° F.), until, after several weeks, the conversion is completed.

The other method is known as *Thénard's process*, according to which a solution of subacetate of lead is prepared in the usual way, and carbonic acid gas passed through it, the filtrate from the precipitate being again used in the preparation of the lead solution. This process has been modified by Benson, so that levigated litharge is mixed with 1 or 2 per cent. of sugar of lead and sufficient water to form a thin paste, which, with frequent stirring, is exposed to the action of carbonic acid until this ceases to be absorbed; the carbonate is washed with water.

Properties.—Commercial carbonate of lead is in pulverulent masses or forms a non-gritty, heavy, white powder, which is not altered on exposure to air unless sulphuretted hydrogen be present, when it turns black. It is inodorous, and at first tasteless, but gradually develops a slight sweetish and metallic taste. It is insoluble in water and alcohol, but dissolves with effervescence in diluted acetic or nitric acid. The solutions yield with sulphuric acid a white, and with potassium iodide a yellow, precipitate. The white precipitates occasioned in the solution by soda and potassa are soluble in an excess of the precipitant. Heated to 155° C. (311° F.), carbonate of lead parts with its water; near 180° C. (356° F.) it begins to lose carbonic acid and turns yellow, and when heated before the blowpipe upon charcoal it yields metallic globules of lead, surrounded by a red-dish-yellow incrustation.

Tests.—Carbonate of lead may be adulterated with the sulphates of lead, barium, or calcium, which would be left behind as a white residue upon treatment with dilute nitric acid; only a trifling residue should be left. On adding to this solution an excess of caustic soda, the white precipitate at first formed should be completely dissolved (calcium salt),

and this alkaline solution should not be rendered permanently turbid on the addition of 1 drop of diluted sulphuric acid (barium carbonate); but on precipitating the solution completely with sulphuric acid the filtrate should be colorless, and should not be precipitated or colored by potassium ferrocyanide (zinc, etc.) or by an excess of ammonia (copper, alumina, *P. U.*). The solution in diluted nitric acid, on being completely precipitated by sulphuretted hydrogen, should yield a filtrate which is not rendered turbid by sulphuric acid (barium and calcium carbonate), nor "on evaporation leave more than a trifling residue (zinc, earths, alkalies)." — *U. S.* On heating lead carbonate to redness it should not be charred (organic matters), and should leave at least 85 per cent. of oxide of lead.

Composition.—White lead is an oxycarbonate, and has the formula given above, in which case it will leave a residue of 86.2 per cent. upon being heated to redness. But the composition may vary from the presence of other oxycarbonates, and the residue left on ignition has been found as low as 83.7 and as high as 86.7 per cent.

Pharmaceutical Uses.—White lead is used in preparing *Liq. gutta-perchæ*, *U. S.*, *Br.*, and is an ingredient in some plasters and in *Ung. plumbi carbonatis*, *U. S.*, *Br.*

Medical Action and Uses.—This preparation is only used externally in the form of a powder to protect irritated surfaces, as in *erythema*, *erysipelas*, *intertrigo*, etc., and to produce constriction of the congested skin. It should never be applied where the cuticle is broken, as it is one of the most poisonous of the salts of lead. It enters into an official ointment, and it is sometimes used in the form of white paint, mixed with linseed oil, as an application to superficial *burns* and *scalds*, but care should be taken to apply it only to the unbroken skin.

PLUMBI IODIDUM, *U. S.*, *Br.*—IODIDE OF LEAD.

Plumbum iodatum, *P. G.*; *Ioduretum plumbicum*.—*Iodure de plomb*, *Fr.*; *Jodblei*, *G.*
Formula PbI_2 . Molecular weight 459.7.

Preparation.—Take of Nitrate of Lead, Iodide of Potassium, each 4 ounces; Distilled Water a sufficiency. Dissolve the nitrate of lead, by the aid of heat, in $1\frac{1}{2}$ pints and the iodide of potassium in $\frac{1}{2}$ pint of the water, and mix the solutions. Collect the precipitate on a filter, wash it with distilled water, and dry it at a gentle heat.—*Br.*

The reaction between the two salts results in the production of nitrate of potassium, which remains in solution, and iodide of lead, which precipitates; $Pb_2NO_3 + 2KI$ yields $2KNO_3 + PbI_2$. The quantities ordered by the Pharmacopœia are almost exactly in equivalent proportions, and the yield is $5\frac{1}{2}$ ounces. Boudet (1847) ascertained that acetate of lead cannot be advantageously used in the preparation of the iodide, inasmuch as double iodide of lead and potassium is invariably produced, and remains dissolved in the newly-formed potassium acetate. The nitrate does not exert any similar influence; hence nearly the whole theoretical quantity of lead iodide is obtained by the official process.

Properties.—Iodide of lead, if precipitated in the cold, is a bright-yellow powder, and if obtained from boiling solutions crystallizes in thin, shining, golden-yellow scales. It has the spec. grav. 6.1, is inodorous, of a slight metallic taste, and when heated turns brick-red, blackish-brown, and, if air be excluded, fuses to a red-brown liquid, and volatilizes, partly undecomposed, at a strong red heat; on cooling it gradually acquires again its yellow color. When heated in contact with air it melts, iodine is given off, and oxyiodide of lead remains behind, having an orange-yellow or amber-yellow color. It is permanent in a dry atmosphere, but when exposed to the light while moist is slowly decomposed, binoxide and carbonate of lead being formed, besides free iodine. Denot (1834) ascertained that it requires 1235 parts of cold and 187 parts of boiling water for solution. According to Lassaigne (1831), the aqueous solution, saturated at $20^\circ C.$ ($68^\circ F.$), contains .17 per cent. (1 in 590), and at $100^\circ C.$.39 per cent. (1 in 200), of iodide of lead. The *U. S.* and German Pharmacopœias give its solubility in cold water (of $15^\circ C.$) as being 1 in about 2000 parts. These solutions are colorless and neutral to test-paper. The salt dissolves more readily in solutions of ammonium chloride and of soluble iodides and alkali acetates, and is at least partly converted into double iodides. Alcohol dissolves very little of the salt, and, according to Vogel, boiling ether decomposes it, dissolving iodine and leaving pale-yellow oxyiodide.

Tests.—Its purity is ascertained from the properties described. The presence of a double compound with potassium iodide is indicated by the lighter color of the product, and is proven by dissolving a sample in warm solution of ammonium chloride, which leaves lead chromate undissolved, precipitating the lead with either sulphuric or hydro-

sulphuric acid, evaporating the filtrate to dryness, and igniting, when no fixed residue should be left. The presence of lead oxyiodide or chromate renders the salt incompletely soluble in hot water. The last-named compound dissolves in caustic potassa or soda with a yellow color, while the solution of lead iodide in the same reagents is colorless. On triturating 1 part of lead iodide with 2 parts of ammonium chloride, and adding 2 parts of cold water, the mixture should soon acquire a white color, and when heated should form a colorless solution without leaving any residue (lead chromate).

Off. Prep.—Emplast. plumbi iodidi, *Br.*; Unguent. plumbi iodidi, *U. S.*, *Br.*

Medical Action and Uses.—Iodide of lead is generally used as an external application in the form of an ointment, which is official. It has, however, been given internally, with alleged advantage, to diminish malarial enlargement of the *spleen*, in the dose of $\frac{1}{5}$ grain (Gm. 0.013) twice a day in pilular form, and gradually increased.

PLUMBI NITRAS, *U. S.*, *Br.*—NITRATE OF LEAD.

Plumbum nitricum, Nitras (Azotas) plumbicus.—Azotate (Nitrate) de plomb, *Fr.*; *Salpetersaures Bleioxyd, Bleisalpeter, G.*

Formula $Pb(NO_3)_2$. Molecular weight 330.5.

Preparation.—Metallic lead dissolves slowly in warm dilute nitric acid, but litharge or carbonate of lead is readily taken up by the acid, the latter with effervescence of carbonic acid gas. A solution of nitrate of lead is also obtained in the preparation of binoxide of lead from the red oxide by digesting it with dilute nitric acid. If prepared from litharge containing copper, the resulting copper nitrate remains at first in the mother-liquor, but will contaminate the last crops of crystals, necessitating washing with water and recrystallization.

Properties.—Nitrate of lead crystallizes on slow evaporation in colorless transparent octahedrons. When obtained by the cooling of hot solutions the crystals are white and translucent or opaque. It has the specific gravity 4.4, is not altered by exposure, and when heated decrepitates, fuses, and gives off oxygen and nitrous vapors, leaving finally oxide of lead. Kremers (1854) ascertained that 1 part of the salt requires at $10^\circ C.$ ($50^\circ F.$) 2.07, at $25^\circ C.$ ($77^\circ F.$) 1.65, at $45^\circ C.$ ($113^\circ F.$) 1.25, and at the boiling temperature 0.72, parts of water for solution. It is likewise soluble, though less freely, in weak alcoholic liquids, but is nearly insoluble in strong alcohol and in nitric acid. The salt is inodorous, possesses a sweetish astringent and somewhat metallic taste, and deflagrates slightly on being triturated with sulphur or thrown upon red-hot charcoal. Its solution has the reactions of soluble lead salts and of nitrates, contains 62.5 per cent. of lead, and is free from water of crystallization.

Tests.—The aqueous solution, on being completely precipitated by hydrosulphuric acid, should yield a filtrate which on evaporation leaves no fixed residue (zinc, earths, and alkalis). The solution should not be rendered turbid by silver nitrate (chloride), and after having been completely precipitated by sodium sulphate should yield a filtrate which is not colored red by potassium sulphocyanide (iron) nor blue by an excess of ammonia (copper), nor should this ammoniacal liquid be precipitated by ammonium sulphhydrate or ammonium phosphate (zinc, magnesia).

Pharmaceutical Uses.—In the preparation of Plumbi iodidum.

Other Lead Salts.—PLUMBI CHLORIDUM, *Chloride of lead*, $PbCl_2$ (mol. weight 277.3), is obtained by precipitating a solution of lead salt with hydrochloric acid or chloride of sodium. It is a white crystalline powder, which fuses when heated, and congeals to a horn-like mass (*Plumbum cornu*). It is soluble in 105 parts of water, sparingly soluble in dilute hydrochloric acid, and more freely so in the same acid when concentrated. It dissolves also in alkaline acetates and hyposulphites.

PLUMBI TANNAS, *Tannate of lead*, is prepared by dropping a solution of tannin into a solution of acetate of lead, washing and drying the precipitate. It is at first nearly white, but turns gradually brown.

UNGUENTUM PLUMBI TANNICI, PLUMBUM TANNICUM PULIFORME, *s.* CATAPLASMA AD DECUBITUM, *P. G.*, is made by triturating tannin 1 part with solution of subacetate of lead 2 parts, and incorporating the mixture with 17 parts of lard. It is prepared extemporaneously.

Medical Action and Uses.—A solution of nitrate of lead (gr. x to $\frac{3}{4}$) may be employed as a discutient for bruises and local inflammations, but it is much more useful as a deodorizing agent to correct the fetor arising from *gangrenous sores* and *offensive discharges* from the nostrils, ears, vagina, and rectum. It is a very efficient remedy for non-constitutional *ozæna* and a palliative of the syphilitic form. It is best applied by means

of the nasal douche, in a solution containing from 2 to 5 grains to the ounce of water (Gm. 0.12–0.30 in Gm. 32). As a cicatrizing astringent it is very useful in the treatment of *sore nipples* when dissolved in glycerin or brandy in the proportion of 10 grains to the ounce (Gm. 0.60 to Gm. 32). It should be applied after suckling, and the child should not be allowed to take the breast again until the nipple has been thoroughly washed. If the ulcer or fissure is deep, a stronger solution than the above may be required. Powdered nitrate of lead appears to be an efficient application to the sanious fungous ulcers resulting from *onychchia*. After the first dressing, it is said, the pain ceases, the swelling decreases, suppuration is lessened, and the fetid odor is destroyed. As the application is painful, it is recommended that the ulcer be first washed with a strong solution of sulphate of morphia. This lead salt is also stated to have cured several cases of *epithelioma* when its powder was dusted over the affected part several times. *Chloride of lead* has been used externally in an ointment with a view of allaying pain and repressing morbid growth, very much as the ointment of carbonate (or the cerate of subacetate) of lead has been employed. *Tannate of lead* has been similarly applied in ointments and liniments and in the *Cataplasma ad decubitus* above described.

PLUMBI OXIDUM, U. S., Br.—OXIDE OF LEAD.

Lithargyrum, *Plumbum oxydatum*, P. G.—*Litharge*, E.; *Protoxide de plomb*, Fr.; *Bleioryd*, *Bleiglätte*, G.

Formula PbO . Molecular weight 222.5.

Preparation.—Oxide of lead is prepared by combining metallic lead with oxygen derived from the air. If heated to near a white heat, lead begins to volatilize, and in contact with the air burns with a bright white flame to oxide, which was formerly known as *flowers of lead*. When merely heated to fusion the metal oxidizes, forming a yellow amorphous powder known as *massicot*, but at a higher temperature the oxide melts and congeals in crystalline scales known as *litharge*, or *semi-vitrified oxide of lead*. In this state it is obtained in several processes, such as that known as *cupellation*, in which the lead is oxidized, and the litharge, as it forms, removed by a blast, leaving any silver behind which may have been contained in the lead. An identical product is obtained by passing a current of air over molten lead heated to dull redness and constantly renewing the surface.

Properties.—Litharge is a more or less crystalline powder which is composed of small scales varying in color between yellowish and pale brick-red. When of a distinct yellow tint and glossy surface it has been called *argyritis*, *yellow* or *silver litharge* (*Silberglätte*, G.), while the red-tinted kind is sometimes known as *chrysis*, *red* or *gold litharge* (*Goldglätte*, G.). Its density varies between 9.25 and 9.5. It is inodorous and tasteless; in contact with the atmosphere it gradually combines with a little carbonic acid. When heated, it acquires a red-brown color, and at a higher heat fuses, congealing on cooling in scales. In the presence of even a small proportion of silica it congeals to a glass-like mass, and in the presence of charcoal it is reduced to metallic lead. It is soluble in dilute nitric acid and in hot acetic acid, the solutions showing with reagents the behavior of lead salts. It is now generally conceded that oxide of lead is completely insoluble in alcohol and water; according to older statements, it dissolves in 70,000 parts or more of water after prolonged contact. It appears to be somewhat soluble in water under increased pressure, also in glycerin and in solutions of sugar and other carbohydrates, which on being digested with it acquire a brownish color and a caramel-like odor.

Tests.—Oxide of lead should dissolve in diluted nitric acid with very little effervescence (carbonate), and leaving merely a slight residue (lead binoxide); and this solution, when precipitated by sulphuric acid, should yield a filtrate which, on being supersaturated by ammonia, does not acquire a blue color (absence of copper) and does not yield a brown precipitate, or but a slight one, consisting of ferric hydrate; nor should a white precipitate be produced on the further addition of sulphhydrate of ammonium (zinc) or of oxalate of ammonium (calcium). The tests given by the U. S. Pharmacopœia do not indicate the presence of copper or of metallic lead. The latter is detected in the residue left on dissolving the oxide in acetic acid. The amount of carbonic acid is ascertained by the loss occasioned by ignition; according to the German Pharmacopœia, it should not exceed 2 per cent., indicating the presence of not more than about 14 per cent. of oxy-carbonate of lead.

Composition.—Pure oxide of lead consists of 92.82 lead and 7.18 oxygen.

Pharmaceutical Uses.—Oxide of lead is used in the preparation of most lead salts and of plasters, and in preparing digitalin.

Other Oxides and Metallic Lead.—*PLUMBI OXIDUM RUBRUM*, Minium, *P. G.*—Red lead, *E.*; Oxyde rouge de plomb, *Fr.*; Mennige, *G.*—On heating massicot to near 450° C. (840° F.) it gradually combines with more oxygen, and is converted into red lead; the conversion of the denser litharge into red lead is attended with greater difficulties. It is a bright orange-red, granular, crystalline powder, which, on being heated, becomes deeper red, purplish, and finally black, and has a density varying between 8.7 and 9.1. It is partly soluble in dilute nitric acid, leaving binoxide of lead: at a red heat it is converted into litharge, oxygen being given off; and when heated upon charcoal metallic lead is produced. When mixed with about 20 per cent. of sugar and then treated with dilute nitric acid, it is wholly dissolved. When pure it contains 90.66 per cent. of lead and 9.34 of oxygen, its formula being $Pb_3O_4 = 2PbO \cdot PbO_2$. A variety of red lead less dense than the ordinary kind, and of a bright orange-red color, is used as a pigment under the name of *orange mineral* or *Paris red*.

PLUMBI BINOXIDUM.—Peroxide (Binoxide) of lead, Puce oxide of lead, *E.*; Peroxyde (Oxyde puce) de plomb, *Fr.*; Bleihyperoxyd, *G.*—This is left behind as an insoluble powder on treating red lead with diluted nitric acid, and is also produced from solution of lead salts by mixing them with an excess of solution of chlorinated lime or chlorinated soda. It is a dark-brown powder, which, on exposure to the light, slowly gives off oxygen, leaving red lead, and by heat is converted into oxygen and litharge. When triturated with one-eighth of its weight of sugar or with its own weight of oxalic acid, it is reduced to oxide or converted into carbonate. Its mixture with sulphur may be ignited by friction—a behavior which renders it useful in the manufacture of matches. Since it readily parts with one-half of its oxygen, it is a valuable reagent for strychnine and some other organic bodies, yielding colored oxidation-products. Its formula is PbO_2 , and it contains 86.61 lead and 13.39 oxygen.

PLUMBUM.—Lead, *E.*; Plomb, *Fr.*; Blei, *G.* Symbol Pb. Atomicity bivalent or quadrivalent. Atomic weight 206.5.—Lead has been known from the most remote period. It is found in the United States and many other countries, occasionally as oxide, more frequently as carbonate (*white lead ore*), or in combination with other acids. The most abundant lead ore is *galena*, a sulphide of lead, PbS , which is frequently associated with the sulphides of zinc, iron, copper, and silver. The metal is obtained from the galena by roasting it, whereby a portion is oxidized to sulphate of lead, while another portion parts with its sulphur, which escapes as sulphurous acid, the metal being converted into oxide. The newly-formed compounds react with the unaltered galena, forming lead, which fuses, and sulphurous acid, which escapes. A considerably quantity of lead remains in the slag, which is used in a subsequent operation. The extraction of silver is effected by cupellation (see page 267), and the oxide of lead is then reduced to the metallic state by heating it with charcoal.

Lead has a bluish-gray color and a bright metallic lustre. It is a soft metal, and when cooled slowly leaves a mark on being drawn over paper. Its specific gravity is 11.4; it is very malleable and ductile, but less tenacious than most other common metals; fuses at 325° C. (617° F.) and volatilizes at a white heat. On congealing, it expands slightly, but afterward contracts considerably, and under some circumstances it may be obtained crystallized in regular octahedrons. When exposed to a moist atmosphere it is superficially oxidized and becomes covered with a grayish layer. In contact with water and air or in the presence of a minute quantity of ammonia or of nitric acid, the metal is corroded and small quantities of it are held in solution. Sulphates prevent the lead from being dissolved, or, if dissolved, precipitate an insoluble sulphate.

In addition to the three oxides described above, the existence of a suboxide, Pb_2O , has been assumed, but is doubted by many chemists. The *sesquioxide of lead*, $Pb_2O_3 = PbO \cdot PbO_2$, has been obtained as a yellow precipitate by adding chlorinated soda to an alkaline solution of lead, and more recently (1878) by H. Debray as a greenish-brown powder by heating peroxide of lead to 350° C. (662° F.).

There are two series of *lead salts*, in one of which lead is contained in the acidulous radical, while in the other it constitutes the base. The former are called *plumbates*, and are obtained by heating together peroxide of lead with alkaline hydrates; the alkaline plumbates are colorless, decomposed by much water, and yield plumbates of the metals by acting upon metallic salts. The *plumbic salts* are white or colorless, unless colored by the acid; mostly insoluble in water, and then usually soluble in dilute nitric acid. The salts, which are soluble in water, have a sweet and metallic taste and an acid reaction to litmus, and their solutions yield white precipitates with carbonates, sulphates, phosphates, and chlorides, the last of which is slightly soluble in water, but less soluble in hydrochloric acid, while the precipitated sulphate of lead is insoluble in water and dilute sulphuric and hydrochloric acids. Alkalies produce white precipitates of plumbic hydrate, which is insoluble in ammonia, but soluble in potassa and soda. Ferrocyanide of potassium yields a white precipitate. The precipitates by potassium chromate and potassium iodide are characterized by a bright-yellow color; the latter crystallizes from hot solutions in golden-colored scales. Sulphuretted hydrogen precipitates black sulphide of lead, which is insoluble in dilute acids and in sulphhydrate of ammonium. Iron and zinc separate from the solutions of lead salts the lead in the metallic state, and by heating the salts with carbonate of sodium upon charcoal before the blowpipe, metallic globules of lead and a reddish-yellow incrustation of lead oxide are obtained.

Off. Prep.—The following chemical compounds are officinal: Plumbi acetat. Plumbi

carbonas, Plumbi iodidum, Plumbi nitras, Plumbi oxidum; and as solutions in water, Liquor plumbi subacet. and Liq. plumbi subacetat. dilut., *U. S., Br.*

The following pharmaceutical preparations contain compounds of lead: Ceratum plumbi subacet., Emplastrum ammoniaci cum hydrarg., Empl. arnicæ, Empl. asafœtidæ, Empl. capsici, *U. S.*; Empl. belladonnæ, *U. S., Br.*; Empl. calefaciens, Empl. cerati saponis, *Br.*; Empl. ferri, Empl. galbani, Empl. hydrargyri, Empl. opii, Empl. plumbi, Empl. resinæ, Empl. saponis, *U. S., Br.*; Suppositoria plumbi comp., Unguentum plumbi acetatis, *Br.*; Ung. plumbi carbon., Ung. plumbi iodidi, *U. S., Br.*; Ung. plumbi subacet. comp., *Br.*

Medical Action and Uses.—Oxide of lead is seldom used alone. It enters into the composition of lead plaster, and hence of most of the plasters which owe their adhesiveness to that compound. A mixture of oxide of lead with sweet oil has been applied to superficial *burns*, and ordinary white paint, containing litharge, linseed oil, and oil of turpentine, is a popular and excellent remedy for the same affection. Care should be taken not to leave it in contact with the broken skin.

PODOPHYLLUM, *U. S.*—MAY-APPLE.

Podophylli rhizoma, *Br.*—*Podophyllum-root*; *Mandrake-root*, *E.*; *Rhizome de podophyllum*, *Fr.*; *Fussblattwurzel*, *G.*

The rhizome of *Podophyllum peltatum*, *Linné*. Bentley and Trimen, *Med. Plants*, 17. *Nat. Ord.*—Berberidaceæ.

Origin.—Mandrake is an herbaceous perennial growing in rich woodlands in Canada and the United States. The pale-green stem is about 10 or 12 inches (25 or 30 Cm.) high, and bears at its summit two peltate, deeply five- or seven-lobed leaves, which are 4 to 6 inches (10–15 Cm.) in diameter, and a single white flower with six or nine petals and twice the number of hypogynous stamens. The flowerless stems frequently bear only a single leaf. The fruit is a yellowish, oval, fleshy berry, and contains twelve or more seeds, which are enclosed in a pulpy arillus. The rhizome is collected in autumn.

Description.—The rhizome is horizontal, several feet long, but as found in commerce is always in fragments varying from 1 to 6 or 8 inches (3 to 20 Cm.) in length. It consists of joints or annual shoots, 1 to 3 inches (25 to 75 Mm.) long, $\frac{1}{4}$ to $\frac{1}{2}$ inch (3–6 Mm.) thick, and marked with distant leaf-sears. The end of each joint is enlarged to the diameter of about half an inch (12 Mm.), is depressed globular in shape, and occasionally branching, has approximate leaf-sears, on the upper side a circular depressed

FIG. 223.

Rhizome of *Podophyllum peltatum*, *Linné*.

stem-scar containing one or two rows of wood-bundles, and on the lower side is beset with from eight to twelve nearly simple rootlets. Rhizome and rootlets are of a yellowish- or reddish-brown color externally, smooth or with longitudinal wrinkles, very brittle, and therefore the radicles often detached; nearly inodorous, and of a sweetish somewhat bitter and acrid taste. The rhizome is white and mealy inside, and has a rather thick bark and a thin circle of yellowish wood-bundles enclosing a compact central pith. The rootlets have a thick white bark and a thin yellowish central cord.

Constituents.—The analysis of podophyllum by J. R. Lewis (1847) showed the presence of starch and other common vegetable principles, and of two resins, one soluble, the other insoluble, in ether. According to H. A. Tilden (1859), the former resin predominates largely in the rhizome collected in October, but if collected in April it contains the two resins in nearly the same proportion. The bitter principle was obtained in an impure condition by Hodgson (1831). F. F. Mayer (1863) announced the presence of berberine and another (white) alkaloid, and of saponin. After the precipitation of the resin from the strong alcoholic tincture by means of water we have on several occasions

obtained a yellow precipitate on the addition of hydrochloric acid, which could be recrystallized from alcohol and was regarded as muriate of berberine. Investigations by F. B. Power (1877-78), however, indicate the total absence from the rhizome of any alkaloid; and we have subsequently shown that at all periods of its growth the rhizome is free from alkaloid. Power doubts also the existence of Mayer's saponin, and regards the frothing of the infusion as due to the acid resin, a compound of which seems to constitute the yellow coloring matter. The mother-liquor from which the resin has been precipitated gives indications of the presence of protocathechuic acid, which later investigations (1878) proved, however, not to pre-exist in the rhizome. (See page 1299.)

TINCTURA PODOPHYLLI, Br.—Resin of podophyllum 160 grs.; rectified spirit 20 fl.oz.

Off. Prep.—Abstractum podophylli, Extractum podophylli, Extr. podophylli fluid., U. S.; Resina podophylli, U. S., Br.

Physiological Action.—*On Animals:* Administered by the stomach to dogs and other animals, podophyllin produces retching, salivation, and vomiting, followed by purging, with colic and tenesmus. Hypodermically, its operation is the same, except that it is said not to occasion vomiting. Injected into the cavity of the peritoneum, it appears not to have caused any inflammation of that membrane nor any special symptoms until after a number of hours, when dry retching occurred and purging of glairy mucus mixed with blood. The animal seemed to suffer great pain, its pulse grew rapid and feeble, and death took place by exhaustion. No evidence was given of any special influence of the medicine on the liver. Experiments performed with the direct intention of inquiring into the cholagogue action of the drug have led to diametrically opposite conclusions—on the one hand, that podophyllin diminishes the total amount of the biliary secretion or of its constituents, according to the dose administered; and, on the other hand, that it increases greatly the amount of biliary secretion, preserving the normal proportion of the special biliary matter. The latest judgment in the matter is that expressed in a report to the British Medical Association (1879) of a series of experiments performed on dogs, and which agrees with the conclusion of Rutherford published in 1876. It is as follows: "Podophyllin is a very powerful stimulant of the liver. During the increased secretion of bile the percentage amount of special bile solids is not diminished. If the dose be too large the secretion of bile is not increased. It is a powerful intestinal irritant."

On Man: Workmen employed in pulverizing podophyllum find it excessively irritating to the eyes, nose, mouth, respiratory passages, and even to the skin (*Med. Record*, xii. 357). The resin applied to an ulcer produces its characteristic purgative effects with nausea. Internally, in small doses, it is a very slow and gentle laxative, producing formed or semi-solid stools, but in large doses it is a drastic and persistent purge. Its bitter and nauseous taste, when taken in powder or in solution, causes salivation, but under any form, and however introduced into the system, it has the same effect if it occasions nausea, which it does by irritating the stomach. It excites the secretion of bile, if at all, in the same way as it does that of the saliva, by the reflex influence of the irritation produced by it in the stomach and duodenum. In the case of a woman who took 10 grains of podophyllin severe abdominal pains came on in about 2 hours, but did not last for more than an hour. The most striking symptom was extreme prostration, with sweating and a violent headache, sharp at first, but afterward dull. In 3½ hours from taking the medicine copious vomiting set in and lasted about 8 hours, each paroxysm being attended with purging. There was very little pain, and the patient recovered (*Phila. Med. Times*, xii. 520). It is alleged that its contact with the mouth blunts the sense of taste and causes the salivary glands to swell (*Ibid.*, x. 564). Prof. Rothrock states that the leaves of podophyllum are just as active as the root (*Ibid.*, viii. 96); and Dr. Hilsman relates that a child two years old having eaten a quantity of poke-berries, the next morning it was unable to see and its muscles were all relaxed, the heart was rapid and feeble, and the extremities cold, and it had a convulsion. After recovery it was affected with urticaria (*Med. Record*, xix. 27). These phenomena appear to us to have been the effect of indigestion, and not of a specific poison.

According to Podwyssotski (*Arch. f. Pathol. u. Pharm.*, xiii. 29), the essential constituent of podophyllum is podophyllotoxin, of which he says that the dose is from one-fourth to one-third of a grain for an adult.

Medical Uses.—Podophyllum has, like jalap, the excellent quality of causing a slow but complete evacuation of the bowels, without greatly tending to render them torpid, provided it be given in suitable doses. This quality makes it useful in habitual constipation. For this purpose ¼ grain (Gm. 0.01) of podophyllin with ½ grain (Gm. 0.013) of extract of belladonna, 1 grain (Gm. 0.06) of extract of hyoscyamus, and a

grain (Gm. 0.06) of soap may be made into a pill to be taken at bed time. Like other active cathartics, podophyllin in removing constipation removes also one of the causes which tend to prolong constipation—the condition which is generally spoken of as *torpor of the liver*, and which is attended with hepatic fulness and perhaps some yellowness of the skin, and which is, in fact, generally due to the infarction of the excretory ducts of the liver with inspissated bile. It nearly always arises from sluggish habits of living, imprudence in diet, and neglect of the function of defecation. In the constipation produced by *lead* the following formula may be employed: $\mathcal{R}$. Podophyllin gr. ss; Ext. nucis vom. gr. j; Ext. belladonnæ gr. ss; for a pill to be taken two or three times a day.

The dose of powdered podophyllum as a purgative is from 10 to 20 grains (Gm. 0.60–1.20); the dose of the extract is about the same; as a laxative, from 5 to 10 grains. The strength of resin of podophyllum is uncertain, and its dose varies from $\frac{1}{8}$ grain to 1 grain (Gm. 0.01–0.06) and upward. It seldom begins to act in less than 12 hours. It has been given in varnished capsules, which are supposed not to dissolve before reaching the duodenum, and thus the nausea and gastric irritation are alleged to be mitigated. The following may be found a convenient formula: $\mathcal{R}$. Podophyllin gr. ij; tincture of ginger fʒij; diluted alcohol to fʒij. $\mathcal{M}$.—S. A teaspoonful in a wine-glassful of water as a habitual laxative in constipation. Braun states the dose of podophyllin to be for a child of thirteen years from $\frac{1}{8}$ to $\frac{1}{4}$ grain, and under one year from $\frac{1}{12}$ to $\frac{1}{8}$ grain; and of podophyllotoxin, for children under one year, from $\frac{1}{80}$ to $\frac{1}{40}$ grain; up to four years, $\frac{1}{30}$ to $\frac{1}{15}$ gr.; and above that age $\frac{1}{10}$ to $\frac{1}{4}$ grain. It is most conveniently dissolved in the proportion of $\frac{3}{4}$ grain in about 100 drops of rectified spirit. Of this solution from 2 to 10 drops may be given in a teaspoonful of syrup (*Practitioner*, xxviii. 54).

POLYGALA.—BITTER POLYGALA.

Polygale, Laitier, Fr.; *Kreuzblume*, *Milchwurz*, G.

The root and herb of *Polygala rubella*. Willdenow, s. *P. polygama*, Walter.

Nat. Ord.—Polygalaceæ.

Description.—The bitter polygala or *bitter milkwort*, which has been dismissed from the last U. S. Pharmacopeia, is a biennial herb growing in dry fields and pastures from Canada southward to the Gulf of Mexico. It has a fusiform root and numerous glabrous nearly simple stems which are 6 to 8 inches (15–20 Cm.) high, and bear a terminal narrow raceme of about fifteen to twenty-five purple, finally pendulous flowers. The leaves are alternate, linear-oblong or oblanceolate, narrowed below, obtuse, and somewhat mucronate. The flowers are showy and conspicuously crested; racemes of inconspicuous flowers are produced on procumbent stems, and usually fertilized in the bud. The plant is without odor and has a bitter taste.

Allied Species.—*POL. SANGUINEA*, Linné. It grows in similar localities to the preceding, has the stem fastigiate branched above and leafy to the top; narrow linear or lance-linear leaves, and terminal globular heads of dark-red and inconspicuously crested flowers. Several others, like *Pol. fastigiata*, Nuttall, and *Pol. Nuttallii*, Torrey et Gray, are closely related to it.

POL. AMARA, Linné. It grows in mountainous woods and meadows of Europe, is about 6 inches (15 Cm.) high, has rosulate obovate or spatulate radical leaves, smaller linear or oblong linear stem-leaves, and lax racemes of blue flowers. It is used in Europe as *Herba polygalæ*.

POL. VULGARIS, Linné. A common European perennial with ascending stems, 5 to 9 inches (12–22 Cm.) long, lanceolate or spatulate radical leaves, longer linear-lanceolate stem-leaves, and short or lax and elongated racemes of blue or purplish flowers.

POL. MAJOR, Jacquin. It is a perennial herb of South-eastern Europe, the root of which is used as *Radix polygalæ hungaricæ*. This is about 1½ inches (38 Mm.) long and $\frac{1}{8}$ inch (4 Mm.) thick, is somewhat branched, has a thin pale yellowish-brown bark and a thick cylindrical woody medullum, is nearly inodorous, and has a sweetish, unpleasant, acrid, and slightly bitter taste.

POL. SERPENTARIA, Ecklon et Zeyher, is indigenous to Southern Africa, where the root is used as an alexipharmic. It is about 8 inches (20 Cm.) long, light-brown, and has a thin, internally reddish-brown bark and a brownish or yellowish wood.

POL. VENENOSA, Jacquin, a shrub of Java, with large oblong or obovate leaves, is considered to be poisonous.

SOULAMEA AMARA, Lamarck, indigenous to the Moluccas, is a shrub or tree, all parts of which are intensely bitter and are reputed to possess anti-periodic properties.

MONNINA POLYSTACHIYA, Ruiz et Pavon, is a Peruvian shrub, the root-bark of which contains saponin, and is used there in diarrhœa and as a substitute for soap in washing and in polishing metals.

Constituents.—Reinsch (1839) obtained from *Polygala amara* small quantities of

solid volatile oil, tannin, and wax, considerable pectin, and a crystalline compound, *polygalamarin*, which has a very bitter taste and foams considerably when agitated with water.

Medical Action and Uses.—*Polygala rubella* is said to be closely analogous in medicinal virtues to *P. amara* of Europe. Some of the most recent European works on the materia medica reject the latter altogether. It is, however, a mild bitter tonic, with some influence in *bronchial catarrh*, and may be convenient in domestic medicine, but scarcely deserves an official rank. *P. vulgaris* possesses the same virtues essentially. Its active principle is analogous to senegin.

POTASSA, U. S.—PotASSA.

Potassa caustica, Br.; *Kali causticum fusum*, P. G.; *Potassæ (Potassii) hydras*, *Kali hydricum fusum*, *Oxydum potassicum*, *Lapis causticus chirurgorum*.—*Caustic potash*, *Potassium hydrate*, E.; *Potasse caustique*, *Potasse fondue*, *Pierre à cautère*, Fr.; *Aetz-kali*, G.

Formula KHO. Molecular weight 56.

Preparation.—Take of Solution of Potash 2 pints. Boil down rapidly in a clean silver vessel until there remains a clear fluid of oily consistence, a drop of which, when removed on a warm glass rod, solidifies on cooling. Pour this into proper moulds, and when it has solidified, and while it is still warm, put it into stoppered bottles.—*Br.*

The process by which the solution is made is described and explained on p. 916. This solution is evaporated, and the remaining potassium hydrate fused until ebullition ceases, and a glass plate laid upon the vessel ceases to become moist from condensed water; the fused mass is then poured upon a cold iron plate, and after congealing broken into smaller pieces, or it is poured into clean cylindrical iron moulds which have been previously warmed. If it is desired to obtain the potassa in powder, the melted mass while cooling is briskly stirred with a silver spatula, or the solid pieces are rapidly triturated in a warm iron mortar. The finished product should in all cases be at once put into well-stopped bottles made of hard glass. Vessels made of glass, porcelain, copper, and of most other materials are corroded by the concentrated solution and the fused hydrate; the operation must therefore be performed in a vessel of silver or of well-cleaned iron.

Properties.—Caustic potassa is either pulverulent or in irregular pieces of crystalline texture: more generally it is in dry white cylindrical pieces, which break readily with a crystalline and somewhat translucent fracture. It is inodorous or has a faint odor of lye; its taste is strongly caustic and acridly alkaline. It dissolves at 15° C. (59° F.) in 0.47 parts of water (Bineau) and in 2 parts of alcohol, and is much more soluble in both liquids at the boiling temperature; the taste and reaction of these solutions are strongly alkaline. The alcoholic solution is yellowish, and on keeping turns brown. Potassa is but slightly soluble in ether. On exposure to the air it rapidly absorbs moisture, liquefies, and combines with carbonic acid. When heated it fuses to a colorless oily liquid, and in a strong red heat it slowly volatilizes, forming white acid vapors. The aqueous solution has the properties and chemical behavior of liquor potassæ (see page 917).

Tests.—Most of the salts likely to be present in caustic potassa are insoluble in alcohol, and are therefore precipitated if the potassa is dissolved in 2 parts of water and the solution mixed with 4 parts of alcohol; only a scanty precipitate (sulphate, silicate, and nitrate of potassium, alumina, ferric oxide) or a small amount of dense watery liquid (potassium carbonate) should be separated. Minute quantities of chloride and sulphate are usually present, indicated by the white turbidity produced with silver nitrate and with barium chloride in the solution acidulated with nitric acid. For the detection of small quantities of nitrate Hager recommends a freshly-prepared mixture of 3.5 Ccm. of sulphuric acid, 7 Ccm. of water, and a little sodium chloride; while still hot about 1 Gm. of potassa is dropped in, and the test-tube is closed with a small paper filter, the point of which is moistened with a solution of potassium iodide; the liberation of iodine indicates the presence of nitric acid. 1 part of potassa should yield with 2 parts of distilled water a colorless solution (absence of organic matter), and on "boiling this with 15 parts of lime-water a filtrate should be obtained which on being poured into an excess of nitric acid does not evolve any gas-bubbles."—*P. G.* This test admits the presence of 3.9 per cent of potassium carbonate. "To neutralize 2.8 Gm. of potassa should require not less than 45 Ccm. of the volumetric solution of oxalic acid, corresponding to at least 90 per

cent. of absolute hydrate of potassium."—*U. S.* This test is without value unless the total absence of soda is ascertained.

An impure potassa of a deep-gray or greenish color is sometimes met with. It is unfit for medicinal purposes, and may be purified by treating it with alcohol, which dissolves the alkali, and evaporating this solution to dryness.

Composition.—The formula of potassa is given above. When pure it contains 16.07 per cent. H_2O and 83.93 per cent. K_2O , but as met with in commerce there is usually an excess of water, amounting to 6 or 8 per cent.

Pharmaceutical Uses.—Potassa is used in the preparation of *Æther*, *Liquor potassæ*, *Potassa cum calce*, *Potass. iodidum*, *U. S.*, and *Potass. permanganas*, *Br.*

Metallic Potassium and Salts.—**POTASSIUM**, or **KALIUM**, was first isolated by Humphrey Davy (1807), and is obtained with some difficulty by heating hydrate or sulphide of potassium with metallic iron, in which case ferrie oxide or sulphide is formed; or an intimate mixture of potassium carbonate and charcoal is heated to strong redness, when carbonic oxide is produced, and the metal distills into a receiver containing petroleum.

It is silver gray, of a strong metallic lustre, harder than sodium, but softer than lead, fuses at $58^\circ C.$ ($136.4^\circ F.$), is brittle at the freezing-point of water, and at a red heat volatilizes, forming green vapors. Its density is 0.865, its atomic weight 39, and its atomicity univalent. It has a great affinity for oxygen, and when thrown upon water decomposes this liquid, melts, and burns with a purple flame. It must be preserved under petroleum naphtha, which is free from oxygen. There are three oxides of potassium known—the *monoxide*, K_2O , *dioxide*, K_2O_2 , and *tetroxide*, K_2O_4 , of which only the former is of importance on account of the uses in medicine and the arts to which its combinations with water and acids are put.

SALTS OF POTASSIUM. Potassa is a very strong base, and completely neutralizes the strongest acids. The salts are colorless, unless the acid has a distinct color, and are neutral to test-paper, except those with weak acids, which have a distinct alkaline reaction. They are mostly readily soluble in water, and in such solutions, if not too dilute, are precipitated in a gelatinous condition by hydrofluosilicic acid, and in a crystalline form by perchlorate of ammonium, tartaric acid, acid tartrate of sodium, platinic chloride, and picrate of sodium. The last two precipitates are yellow, the others white. When heated before the blowpipe the potassium salts impart a purplish tinge to the flame, which is masked by the presence of a small quantity of sodium salt. The yellow color of the latter is absorbed by looking at the flame through blue glass, and the potassium flame becomes then visible.

Physiological Action.—*On Animals*: Injected into the veins of dogs, 5 grains of caustic potassa dissolved in water produced difficult breathing, exhaustion, paralysis, and speedy death. Larger doses administered to horses by the veins were not fatal, but, besides causing signs of distress, produced increased urination. Given to dogs by the stomach, potassa excites violent and fatal gastro-enteritis.

On Man: Potassa is one of the strongest caustics. It destroys animal tissue by abstracting water, neutralizing free acids, decomposing nitrogenous compounds, and forming solutions of fibrin, albumen, and gelatin. Between the fingers it has a soapy feel. In contact with the soft tissues it causes severe burning pain, and produces a moist, ashen, and then black, leathery slough, which leaves a granulating ulcer behind it.

The symptoms of poisoning by a solution of potassa are these: An acrid, urinous, and caustic taste in the mouth, burning in the throat; nausea, and vomiting of alkaline matters, which are usually bloody; intense pain in the fauces, œsophagus, stomach, and bowels; diarrhœa, convulsions, delirium; a cold, clammy skin, and, if the dose has been large and not instantly rejected, speedy death. Sometimes death takes place from inflammation of the larynx; sometimes, after several weeks from the gastro-intestinal lesions (which consist of more or less destruction of the mucous membrane, etc.); and, finally, it may occur after several months from stricture of the œsophagus.

In small or medicinal doses potassa increases the amount of urine secreted, rendering it less acid; in larger or in long-continued doses it diminishes the coagulability of the blood, and may give rise to a cachectic condition, with paleness and œdema of the skin, passive hæmorrhages, and general emaciation—a state identical with that occurring in scurvy.

Medical Uses.—Potassa in solution is used as an antacid to correct *acidity of the stomach* which proceeds either from fermentation of the contents of the organ or from an excessive amount of its proper secretion, and which is accompanied with heartburn, sour eructations, aphthæ, spasm of the œsophagus, vomiting, gastric cramp, colic, tympanites, irregular diarrhœa, etc. In treating such conditions with alkalies the acidity is indeed palliated, but its cause must be removed to make a cure certain, and that is usually best secured by means of tonic medicines and regimen. For the relief of *calculous disorders* potassa is less appropriate than soda and its carbonates. 20 minims (Gm. 1.30) of solu-

tion of potassa largely diluted are said to prevent and also to relieve *strangury* from *cantharides*. Formerly, this medicine was considered as almost a specific in the treatment of glandular *scrofula*, but the influence of the hygienic conditions existing at the same time appears to have been underrated. It should not, however, be neglected, but given in the dose of 5 drops (Gm. 0.30), largely diluted, after meals. Solution of potassa is useful in some cases of *acne rosacea*, and in the treatment of *boils* it has been thought efficient.

Externally, potassa is used chiefly as a caustic to promote the healing of callous ulcers and sinuses and to destroy fungous granulations. It has been especially employed to destroy *chancres* in their first stage and to cauterize *poisoned wounds*. It is much used in the treatment of *ingrown nail* and *paronychia*, and was formerly employed for opening *scrofulous abscesses*. It has been applied as a counter-irritant in diseases of the *hip-joint* and other joints and for the purpose of exciting inflammation in the ends of *ununioned fractured bones*; but these uses, as well as its application to *carbuncles*, *erectile tumors*, *varicose veins*, and to the spine in *tetanus*, are wellnigh obsolete, having been superseded by more efficient and less painful remedies. The same may be said of its use in the treatment of *urethral stricture*. It is one of the most convenient agents for establishing *issues*. To prevent the caustic action from spreading laterally, a piece of adhesive plaster should be applied first, with an aperture of the size of the intended issue. Upon the skin thus exposed and moistened a small portion of fused potassa is laid, and the degree of its action regulated by the duration of its contact. The action may be arrested at any point by a sponge or cloth wet with vinegar. Milder action may be secured by applying the stick of fused potassa, duly covered, except at one end, with shellac varnish or sealing-wax, and maintaining its contact for a longer or shorter time according to the effect desired. (For other uses of potassa see LIQUOR POTASSÆ and POTASSA C. CALCE.)

POTASSA CUM CALCE, U. S.—POTASSA WITH LIME.

Pulvis causticus cum calce, *Pulvis causticus Viennensis (Londinensis)*.—*Vienna caustic*, E.; *Caustique (Poudre) de Vienne*, Fr.; *Wiener Aetzpulver*, G.

Preparation.—Potassa, Lime, of each 50 parts (1 oz.). Rub them together so as to form a powder, and keep it in a well-stopped bottle.—U. S.

Properties.—This is a grayish-white powder of a strongly caustic taste and alkaline reaction. When exposed to the air it absorbs moisture and carbonic acid. Treated with diluted nitric or hydrochloric acid, it dissolves completely with slight effervescence, and yields a solution in which both potassium and calcium are indicated by reagents.

CAUSTICUM CUM POTASSA ET CALCE, *F. Cod.*, is a stronger preparation, known in France as *caustique de Filhos*, and made by fusing 100 parts of caustic potassa, adding thereto 10 parts of powdered burned lime, and pouring the mass into lead tubes of suitable size to harden.

CAUSTICUM COMMUNE MITIUS. Under this name a preparation was formerly employed which was made either by intimately mixing equal weights of soft soap and powdered burned lime, or caustic potassa was dissolved in three times its weight of water, and a sufficient amount of lime added until the whole was converted into a pasty mass.

Medical Action and Uses.—This caustic is milder in its operation than pure potassa. When applied in a dry state to the skin, it absorbs moisture from it and from the air, and partially deliquesces. It is best employed after being reduced to a paste with a little alcohol. Its action may be limited laterally by means of adhesive plaster, and in depth by the duration of its contact. The sticks of Filhos's caustic may be protected from the air by waxed paper, by sealing-wax, gutta-percha, or varnish. For still further mitigating the caustic action of the potassa in this preparation the alkali may be fused with gutta-percha in any required proportion. Its uses are the same as those of potassa.

POTASSA SULPHURATA, U. S., Br.—SULPHURATED POTASSA.

Potassii sulphuretum, U. S. 1870; *Kalium sulfuratum*, P. G.; *Hepar sulphuris*.—*Sulphuret of potassium*, *Liver of sulphur*, E.; *Sulfure de potasse*, *Foie de soufre*, Fr.; *Schwefelleber*, G.

Origin.—The name "liver of sulphur" was introduced by Basilius Valentinus in the fifteenth century, but the process of melting together sulphur with an alkali was known already to Albertus Magnus in the thirteenth century, and the solubility of sulphur in alkalis to Geber in the eighth century. Spielmann (1766) recommended the

preparation of liver of sulphur from 2 parts of carbonate of potash and 1 part of sulphur, in which proportion the ingredients are still employed.

Preparation.—Sublimed Sulphur 1 part; Carbonate of Potassium 2 parts. Rub the carbonate of potassium, previously dried, with the sulphur, and heat the mixture gradually in a covered crucible until it ceases to swell and is completely melted. Then pour the liquid on a marble slab, and when it has solidified and become cold break it into pieces, and keep them in a well-stopped bottle of hard glass.—*U. S.*

The different pharmacopœias prepare this compound in a like manner, and use the sulphur and carbonate of potassium in the proportion given above. On heating the mixture an evolution of carbonic acid takes place, causing the mass to swell, and when this ceases the heat is finally raised to a dull redness, so as to produce perfect fusion (*Br.*), and continued until a small portion of the mass is found to be entirely soluble in water without separating any sulphur (*P. G.*). The crucible must be kept covered to prevent the sulphur from igniting, and after the melted mass has been poured out on a slab, flagstone, an oiled iron plate, or into a porcelain mortar, it is either broken into suitable pieces as soon as it has congealed, or first allowed to cool, being in the mean time covered with a porcelain basin or bell-glass, so as to exclude the air as completely as possible (*Br.*). The yield from the quantities given in the formula is about 2½ parts.

(On fusing sulphur with carbonate of potassium the latter is decomposed, with the evolution of carbonic acid gas, the sulphur uniting with the potassium to form a potassium polysulphide, a portion of which is oxidized by the oxygen of the carbonate, in excess over that contained in the carbonic acid gas, to form sulphate or hyposulphite of potassium; $4K_2CO_3 + 5S_2$ yields $K_2SO_4 + 3K_2S_2 + 4CO_2$, and $3K_2CO_3 + 4S_2$ yields $K_2S_2O_3 + 2K_2S_3 + 3CO_2$. But the degree of heat is likewise of importance, since at a high temperature the hyposulphite of potassium is decomposed into pentasulphide and sulphate; $4K_2S_2O_3$ yields $K_2S_5 + 3K_2SO_4$. It is evident from this that products of very different composition are obtained by varying the proportion of the material, or, if this be used in the same relative proportions, by the injudicious application of heat, by which a part of the sulphur may be sublimed. The directions of the Pharmacopœia should therefore be strictly adhered to.

Properties.—Sulphurated potassa, when recently made or well preserved in closed vessels, is in irregular fragments, breaking with a shallow conchoidal fracture and having a liver-brown color, which in contact with moisture changes to greenish-yellow or brown-yellow. It has a slight odor of sulphydric acid, a bitter and acridly alkaline sulphurous taste, and an alkaline reaction to test-paper. It is partly deliquescent on exposure, and yields with water a brownish-yellow solution which has a strong odor of sulphuretted hydrogen, and evolves the latter freely on the addition of hydrochloric or sulphuric acid, sulphur being at the same time deposited. After boiling the hydrochloric acid solution until the sulphuretted hydrogen has been expelled, the liquid, freed from sulphur by filtration, will yield a yellow precipitate with chloride of platinum and a white precipitate with chloride of barium. The acid solution on being neutralized with soda yields, with a saturated solution of sodium bitartrate, a white crystalline precipitate of potassium bitartrate (*U. S.*). The same precipitate is obtained on dissolving sulphurated potassa in 20 parts of water, boiling with excess of acetic acid, filtering, and adding tartaric acid (*P. G.*). About one-half of the weight of sulphurated potassa is dissolved by rectified spirit (*Br.*), the insoluble portion being mainly sulphate of potassium.

When intended for internal use the compound should be perfectly soluble in 2 parts of water. For external use an impurer article, *Kalium sulfuratum ad balneum*, is made like the above, with the exception that impure carbonate of potassium (pearlash) is substituted for the purified.

If not protected from contact with air, sulphuret of potassium becomes green, and afterward gray, being partly converted into carbonate through the carbonic acid of the air, and partly oxidized to hyposulphite, sulphite, and sulphate, sulphur being at the same time liberated.

Tests.—On triturating together 10 parts of sulphurated potassa and 12.69 parts of crystallized sulphate of copper with 60 parts of water, and filtering, the filtrate should remain unaffected by hydrosulphuric acid (presence of at least 56 per cent. of true sulphide of potassium).—(*U. S.*) Hirsch states (*Vergleichende Uebersicht*, page 206) that 10 parts of the freshly-prepared compound, made with potassium carbonate of 90 per cent. purity, will precipitate 9 parts of crystallized copper sulphate, but should be regarded as of good quality if from 7.5 to 8 parts of the latter salt be precipitated; Hager adopts 8 parts of the copper salt as the lowest limit. None of the pharmacopœias give a test

for the detection of soda which may have been partly substituted for the potassa salt; it is best detected by accurately precipitating the aqueous solution with nitrate of lead, evaporating the filtrate, powdering the residue, and leaving it in contact with alcohol of spec. grav. .879, of which 17 parts will dissolve 1 part of sodium nitrate, while potassium nitrate is sparingly soluble. The alcohol, previously saturated with the latter salt, will dissolve the sodium salt, the amount of which may thus be estimated.

Off. Prep.—Unguent. potas. sulphuratæ, Br.

Allied Compounds.—POTASSII SULPHIDUM, Potassium monosulphide, K_2S ; molecular weight 110. Sulphuretted hydrogen gas is conducted into a solution of potassa as long as it is absorbed, and an equal bulk of potassa solution is added. The colorless liquid has a bitter taste and a strongly alkaline reaction, and on evaporation *in vacuo* yields colorless deliquescent quadrangular prisms, containing $5H_2O$, which are somewhat soluble in alcohol.

POTASSII SULPHOCARBONAS, Sulphocarbonate or thiocarbonate of potassium, K_2CS_3 . On agitating a solution of potassium monosulphide with carbon bisulphide the liquid acquires a yellow or red-brown color, according to its concentration and purity, and on careful evaporation at $30^\circ C.$ ($86^\circ F.$) yields orange-yellow deliquescent crystals of the hydrated salt, or a crystalline precipitate of the same salt on mixing the brown liquid with alcohol. It has a cooling, pungent, and somewhat sulphurous taste, and is sparingly soluble in alcohol. On agitating potassa solution with carbon bisulphide a brown liquid containing both carbonate and sulphocarbonate of potassium is obtained. Such a solution has been employed in Europe for the destruction of the phylloxera insect which infests grapevines.

Physiological Action.—Experiments on animals and observations on man show that the local action of this compound is that of an irritant, and even a caustic. Taken internally in doses of several drachms, it causes inflammation of the throat, stomach, and intestine, and sometimes speedy death. The corresponding symptoms are burning in the parts mentioned, vomiting, purging, fever, muscular trembling and spasm, and in fatal cases dyspnoea, a small and irregular pulse, venous congestion of the skin, and loss of sensibility and consciousness. After death the blood is fluid and dark and the alimentary canal inflamed. In medicinal and long-continued doses it is said to give rise to a state of the blood such as mercury occasions—*i. e.* a loss of coagulability—and at the same time to impair the digestion, producing flatulence and discharges of sulphuretted hydrogen.

Medical Uses.—The extremely offensive smell and taste of this preparation have caused its use as an internal medicine to be nearly abandoned; but even if these obstacles had not existed it would scarcely have held its ground against the results of accurate observation. At one time it was thought to be a specific remedy for *membranous croup*, but longer experience showed that the supposed merits of the medicine were, as in so many other cases, due to errors in diagnosis, to mistaking spasmodic croup, which is seldom fatal, for pseudo-membranous laryngitis, from which recovery is rare. It is no longer used, although once regarded as a specific, for *whooping cough*; nor for *pulmonary consumption*, in which it was formerly employed; nor yet for *scrofula*, especially of the glands, which it was once believed to cure; nor does it continue to be prescribed as an antidote in acute poisoning by lead, arsenic, mercury, or copper salts. There is more reason to think it of service in chronic poisoning with mercury and lead. It has been used with doubtful advantage in the treatment of certain forms of *dyspepsia*, apparently those attended with mucous regurgitation or vomiting.

Externally, lotions and ointments made with sulphurated potassa have been much used in the treatment of limited eruptions of *acne*, *impetigo*, *psoriasis*, etc., and for lessening mucous or purulent discharges from the nostrils, ears, vagina, etc. It is sometimes employed in the treatment of *scabies*, as in the following liniment: ℞. Potass. sulphurat. ʒvj; Saponis alb. Oij; Ol. olivæ ʒiv; Ol. thymi ʒij; M. (Jadelot); but less commonly than sulphur itself. It is, however, very efficient, although if thoroughly applied after the skin is softened by a prolonged warm bath, it is apt to produce eruptions of eczema, which require time and treatment for their cure.

The action and uses of baths containing this preparation are as follows: About 4 ounces (Gm. 128) of it are sufficient for a full bath. Such a bath, even at ordinary temperatures, stimulates the skin and is apt to cause sleeplessness, but these and corresponding effects are more decided when the temperature of the water is equal to that of the skin or above it. Hence these baths are contraindicated when fever is present or a tendency to hæmorrhage exists. Such conditions apart, they are often very serviceable in chronic rheumatism, scrofula, cutaneous eruptions, and chronic profluvia from the bowels and urinary organs, and have been used in lead-palsy and other paralysses. They excite copious sweating, and, as above remarked, tend to produce papular and vesicular eruptions of the skin, particularly if the baths are prolonged, as they sometimes are, for several

hours. If these effects, and especially the perspiration, are wanting, a sense of fulness, and indeed a relative plethora, may be induced, which is not free from the dangers before alluded to. In such cases a douche directly applied to the affected part is to be preferred.

Internally, the *dose* of sulphuret of potassium is from 3 to 10 grains (Gm. 0.20–0.60).

POTASSII ACETAS, *U. S., Br.*—ACETATE OF POTASSIUM.

Potassæ acetat, Br.; *Kalium*, s. *Kali aceticum*, P. G.; *Acetas potassicus*, s. *kalicus*, *Terra foliata tartari*.—*Acetate of potash* (*potassa*), E.; *Acétate de potasse*, Fr.; *Kaliumacetat*, *Essigsäures Kali*, G.

Formula $KC_2H_3O_2$. Molecular weight 98.

Preparation.—Take of Carbonate of Potash 20 ounces; Acetic Acid 2 pints or a sufficiency. To the acetic acid, placed in a thin porcelain basin, add gradually the carbonate of potash, filter, acidulate, if necessary, with a few additional drops of the acid, and, having evaporated to dryness, raise the heat cautiously so as to liquefy the product. Allow the basin to cool, and when the salt has solidified, and while it is still warm, break it in fragments and put it into stoppered bottles.—*Br.*

On adding carbonate or bicarbonate of potassium to acetic acid an effervescence of carbonic acid gas takes place, and water and potassium acetate are formed: $K_2CO_3 + 2HC_2H_3O_2$ yields $2KC_2H_3O_2 + H_2O + CO_2$, and $KHCO_3 + HC_2H_3O_2$ yields $KC_2H_3O_2 + H_2O + CO_2$. On the application of heat the carbonic acid which remains dissolved in the water is expelled, and the liquid should now have a neutral or preferably a slightly acid reaction, in which case it contains a slight excess of acetic acid. The evaporation of this solution is effected either by means of a sand-bath or over the naked fire, and the salt may be obtained dry and granulated by continued stirring at about $120^\circ C.$ ($248^\circ F.$); or the dry salt is fused by the cautious application of heat, so as not to char it, after which the melted salt is allowed to solidify. In making this salt bicarbonate of potassium is preferable, in being nearly free from impurities and yielding at once a salt perfectly soluble in water. Carbonate of potassium is less pure, but usually yields a clear solution with acetic acid, which, on being evaporated to dryness and again dissolved in water containing a little acetic acid, leaves some floccules of silica behind, from which it may be filtered and afterward again evaporated.

Acetate of potassium may also be prepared from acetate of lead by precipitating its solution with a slight excess of carbonate of potassium, filtering, acidulating the filtrate with acetic acid, testing with sulphydric acid to ensure its complete freedom from lead, and evaporating.

Properties.—Acetate of potassium is a white salt forming a crystalline soft mass or a dry granular powder, or more frequently it is seen as a satiny, foliaceous, crystalline mass which melts to an oily liquid at about $280^\circ C.$ ($536^\circ F.$), and at a higher temperature evolves acetic acid, acetone, empyreumatic and inflammable products, and leaves potassium carbonate and charcoal. The salt is nearly inodorous, is free from acetous odor, has a warm and somewhat pungently saline taste, and is very deliquescent in the air. It dissolves at $15^\circ C.$ ($59^\circ F.$) in 0.4 (*U. S.*), 0.36 (*P. G.*) part of water, and in 2.5 (*U. S.*), 1.4 (*P. G.*) of alcohol. According to Osann, it dissolves at $2^\circ C.$ ($35.5^\circ F.$) in 0.531 part, at $13.9^\circ C.$ ($57^\circ F.$) in 0.437 part, and at $28.5^\circ C.$ ($83.3^\circ F.$) in 0.321 part of water. The aqueous solution, saturated while boiling, contains 1 part of the salt to 0.125 part of water, and boils at $169^\circ C.$ ($336^\circ F.$) (Berzelius). Cold absolute alcohol dissolves one-third, and at the boiling temperature one-half, its weight of the salt. The alcoholic solution on the addition of ether gives a crystalline precipitate of the salt, and on passing carbonic acid gas through it potassium carbonate is separated and acetic ether produced. The aqueous solution has a nearly neutral but faintly alkaline reaction, disengages acetous vapors on the addition of sulphuric acid, and yields with platinic chloride a yellow, and with sodium bitartrate a white, crystalline precipitate, and it gives with ferric chloride a dark-red color, and on boiling a brown-red precipitate. A solution of the salt in 20 parts of water precipitates potassium bitartrate on the addition of tartaric acid. On triturating the salt with iodine it acquires an indigo-blue color, changing to brown on the addition of water.

Tests.—Acetate of potassium, when strewn upon colorless sulphuric acid, should not impart a dark color to the latter (organic impurities). Its solution in distilled water should not give a precipitate or a turbidity on the addition of hydrosulphuric acid, hydrosulphate of ammonium, or ferrocyanide of potassium (absence of heavy metals). A 2

per cent. solution of the salt should not give more than a faint opalescence with carbonate of sodium (alkaline earths), with chloride of barium (sulphate or carbonate), or, if acidulated by nitric acid, with nitrate of silver. The concentrated aqueous solution of the salt on being dropped into acetic acid should not produce any effervescence (carbonate), and if mixed with an excess of hydrochloric acid and evaporated to dryness the remaining salt should be completely soluble in water (silica from potassium carbonate). "If 4.9 Gm. of acetate of potassium are ignited until gases cease to be evolved, the alkaline residue should require for complete neutralization not less than 49 Ccm. of the volumetric solution of oxalic acid (corresponding to at least 98 per cent. of absolute acetate of potassium)." — *U. S.* Since the other pharmacopœial tests admit only mere traces of other salts, this test is intended to prove the absence of sodium acetate and of more than 2 per cent. of moisture. The latter is more readily estimated by drying the salt at 120° C. (248° F.); considering the hygroscopic nature of the salt, 3 or 4 per cent. of moisture would seem to be admissible. The presence of notable quantities of sodium acetate is best determined by the intense yellow color imparted by the salt to a non-luminous flame. 4.9 Gm. of dry potassium acetate, evaporated to dryness with an excess of hydrochloric acid, leave a residue of KCl weighing 3.72 Gm., or, allowing for 2 per cent. of moisture, 3.645 Gm. The same weight of exsiccated sodium acetate leaves only 3.49 Gm., and of the crystallized sodium salt 2.104 Gm., NaCl.

Pharmaceutical Uses.—Potassium acetate, being unfit for dispensing in the dry state, is always prescribed in solution. For convenience in dispensing the German Pharmacopœia recognizes—

LIQUOR KALII ACETICI, s. KALII ACETICUM SOLUTUM, which contains one-third of its weight of the dry salt, and is prepared by neutralizing 100 parts of acetic acid spec. grav. 1.041 with 48 or 50 parts of potassium bicarbonate, expelling the carbonic acid gas by heat, and diluting with sufficient water to obtain 147 parts. Its specific gravity is 1.176–1.180.

Off. Prep.—For preparing *Liquor ferri acetatis*, *Br.*

Physiological Action.—It acts upon the blood as a solvent and diluent, upon the glands and mucous membranes as a depurative, augments the secretion of bile, urine, and sweat, and does not readily disorder the digestion. In doses of from half an ounce to an ounce (Gm. 16–32) it is a mild laxative. It is decomposed in the system, and is discharged with the urine as carbonate of potassium, rendering this secretion alkaline and increasing its quantity as well as its solid contents. In large and continued doses it is said to occasion renal catarrh, and even bloody urine.

Medical Uses.—The title *sal diureticus* which was formerly applied to this salt it is justly entitled to, and there is good reason to believe that, besides increasing the quantity of the urine secreted, it also promotes the disintegration and discharge with that secretion of various effete and noxious elements. It displays this virtue notably in chronic infarctions of the *liver* accompanied with *jaundice*, in analogous congestions of the *spleen*, *uterus*, and *hemorrhoidal vessels*, and particularly in such conditions resulting from malarial poisoning. In like manner, probably, must be explained its virtues in *gout*, *lithiasis*, *furuncles*, *carbuncles*, and various *cutaneous affections*, as well as in *acute articular rheumatism*. In the last-named disease especially are its virtues conspicuous when it is given in such doses and so frequently as to render the urine alkaline. Like other forms of the alkaline treatment of this disease, it lessens the risk of cardiac complications. In this and other affections distinguished by an excess of uric acid it acts in the same manner as the carbonates of the alkalis.

In several forms of *dropsy* its diuretic virtue is of extreme value. Most conspicuously is it efficient in the dropsy following scarlatina and in other forms of tubular desquamative nephritis. But it is also very efficient in cardiac dropsy and in ascites of hepatic origin. In an inferior degree it is useful in splenic dropsy also. According to circumstances, it may be associated with squill, digitalis, parsley, broom, dandelion, etc. Under the title *potio Riverii* acetate of potassium has long been employed in acute febrile affections as a *diaphoretic*. This draught is made by saturating 2 drachms (Gm. 8) of carbonate of potassium with vinegar, and adding 6 ounces (Gm. 190) of sweetened water. A tablespoonful of it every two hours is the proper dose.

This salt should always be administered in a large quantity of liquid, except when it is prescribed as a diaphoretic. In febrile affections, as a sedative, its *dose* is 10 grains (Gm. 0.60). In acute articular rheumatism 30 grains (Gm. 2) may be given every four hours. As an alterative it may be prescribed in the same or in still larger doses. As a laxative the dose is about $\frac{1}{2}$ ounce (Gm. 16).

POTASSII BICARBONAS, U. S., Br.—BICARBONATE OF POTASSIUM.

Potassæ bicarbonas, Br.; *Kalium bicarbonicum*, P. G.; *Kali carbonicum acidulum*, *Bicarbonas potassicus*, s. *kalicus*.—*Bicarbonate of potash*, E.; *Bicarbonate de potasse*, Fr.; *Kalumbicarbonat*, *Doppelt-kohlensaures Kali*, G.

Formula KHCO_3 . Molecular weight 100.

Preparation.—This salt was first prepared by Cartheuser (1757) from potash and ammonium carbonate. Cavendish originated the process which is still used, acting with carbonic acid gas upon a solution of the carbonate.

Take of Carbonate of Potash 1 pound; Distilled Water 2 pints; Hydrochloric Acid $1\frac{1}{2}$ pints; Water 3 pints; White Marble, in fragments, 1 pound or a sufficiency. Dissolve the carbonate of potash in the distilled water, and filter the solution into a 3-pint bottle capable of being tightly closed by a cork traversed by a glass tube sufficiently long to pass to the bottom of the fluid. Introduce the marble into another bottle in the bottom of which a few small holes have been drilled, and the mouth of which is closed by a cork also traversed by a glass tube, and place the bottle in a jar of the same height as itself, but of rather larger diameter. Connect the two glass tubes air-tight by a caoutchouc tube. The cork of the bottle containing the carbonate of potash having been placed loosely, and that of the bottle containing the marble tightly, in its mouth, pour into the jar surrounding the latter bottle hydrochloric acid previously diluted with the water. When carbonic acid gas has passed through the potash solution for 2 minutes, so as to expel the whole of the air of the apparatus, fix the cork tightly in the neck of the bottle, and let the process go on for a week. At the end of this time numerous crystals of bicarbonate of potash will have formed, which are to be removed, shaken with twice their bulk of cold distilled water, and, after decantation of the water, drained, and dried on filtering-paper by exposure to the air. The mother-liquor, filtered if necessary, and concentrated to one-half at a temperature not exceeding 43.3°C . (110°F .), will yield more crystals. The tube immersed in the solution of carbonate of potash, which should have as large a diameter as possible, may require the occasional removal of the crystals formed within it, in order that the process may not be interrupted.—Br., 1867.

Carbonate of potassium, kept in flat, open vessels in localities where saccharine liquids are undergoing vinous fermentation, is gradually converted into bicarbonate. The same salt is also obtained on passing carbonic acid gas over the moist carbonate. For preparing it on a small scale a rather concentrated solution of carbonate of potassium in water is made, into which carbonic acid gas is conducted. 1 molecule of this gas unites with 1 molecule each of potassium carbonate and water, forming 2 molecules of the bicarbonate, thus: $\text{K}_2\text{CO}_3 + \text{H}_2\text{O} + \text{CO}_2 = 2\text{KHCO}_3$. The bicarbonate being less soluble in water than the carbonate, a portion of it crystallizes out, the crystals being larger if they form slowly. To accomplish this the British Pharmacopœia directs a peculiar arrangement of the apparatus, by means of which the generation of carbonic acid is regulated by the rapidity with which it is absorbed by the solution, an excess of it remaining in the apparatus, displacing the acid liquid from the bottle containing the marble, thereby completely stopping the further generation of the gas until after partial absorption has taken place. When somewhat larger quantities of the salt are to be prepared, it is convenient to divide the solution among three or more vessels and pass the gas successively through them. In all cases the delivery-tube of the gas dipping into the solution should be of large bore, and preferably widened in the shape of a funnel, which precaution will prevent the closing of the tube by the crystallizing bicarbonate. Since the commercial carbonate of potassium is usually contaminated with silicate, silica is separated by the carbonic acid in the form of floccula, and may afterward be removed by agitating the crystals with cold water and decanting the liquid with the suspended silica. The remaining solution is then filtered and evaporated, or the liquid may be heated to a temperature not exceeding 60°C . (140°F .) until the crystals are dissolved, then rapidly filtered while warm, and, if necessary, further concentrated at the temperature mentioned, and set aside to crystallize. The complete saturation of the solution with carbonic acid is conveniently ascertained, according to Hirsch, by means of a very dilute solution of barium chloride, which yields no precipitate in the cold with bicarbonate, but at once a white one with carbonate of potassium. The crystals should be drained and dried at the ordinary temperature.

329,149 pounds of bicarbonate of potassium and saleratus were imported into the United States in 1876, and 1,571,012 pounds in 1883.

Properties.—Bicarbonate of potassium crystallizes in transparent, colorless, monoclinic prisms, which are permanent in the air, inodorous, and have a saline and slightly

alkaline but not a caustic taste. When heated to near 200° C. (392° F.) it gives off carbonic acid and water, suffering a loss of 31 per cent. The salt is very sparingly soluble in alcohol, and at 15° C. (59° F.) dissolves in 3.2 (*U. S.*), 4 (*P. G.*) parts of water. According to Poggiale, 100 parts of water dissolve at 10° C. (50° F.) 23.23 parts, at 20° C. (68° F.) 26.91 parts, and at 60° C. (140° F.) 41.35 parts, of the salt; the solution has a slight alkaline reaction to test-paper, effervesces briskly on the addition of acids, yields with an excess of tartaric acid a white crystalline precipitate of potassium bitartrate, and parts with one-half its carbonic acid slowly when evaporated *in vacuo*, and rapidly when heated to the boiling-point. 5 Gm. of the salt exposed to a low red heat leave 3.45 Gm. of a white residue consisting of carbonate of potassium, which requires for exact neutralization 50 Ccm. of the volumetric solution of oxalic acid. 20 grains of bicarbonate of potassium neutralize 14 grains of citric acid or 15 grains of tartaric acid.—*Br.* A less pure bicarbonate of potassium in a pulverulent state is met with in commerce under the name of *sal aeratus*, but much sold as such is bicarbonate of sodium.

Tests.—The presence of carbonate of potassium causes the bicarbonate to become moist on exposure, and its solution in cold water to yield a white precipitate with sulphate of magnesium and a yellow or brick-red one with corrosive sublimate; the latter reagent produces a white precipitate with pure bicarbonate of potassium. The limit of carbonate is ascertained as follows: "If 1 Gm. of the salt be dissolved in 200 Ccm. of cold water, and the solution be carefully mixed, without agitation, with a solution of 1.22 Gm. of chloride of barium in 200 Ccm. of cold water, no precipitate or opalescence should make its appearance within 10 minutes."—*U. S.* Metallic salts, if present as impurities, remain behind on dissolving the salt in water, or are indicated by producing a precipitate on the addition of sulphuretted hydrogen. Other salts of potassium are best detected in the solution in 20 parts of water acidulated with nitric acid by nitrate of silver (chloride) or nitrate of barium (sulphate); no precipitate should be produced, but an opalescence is admissible. Sodium salts present as impurities will impart an intense yellow color to a non-luminous flame. The complete solubility of the salt in 4 parts of cold water excludes notable quantities of sodium bicarbonate.

Composition.—Bicarbonate of potassium represents 47 per cent. K_2O , 44 per cent. CO_2 , and 9 per cent. H_2O .

Pharmaceutical Uses.—In the preparation of *Liq. magnesii citratis*, *U. S.*, *Br.*; *Liq. potasse*, *Liq. potass. arsenit.*, *Liq. potass. citrat.*, *U. S.*; *Liq. potass. efferves.*, *Br.*; *Mistura potass. citrat.*, *U. S.*

Medical Action and Uses.—Bicarbonate of potassium increases the quantity of the urine and renders it alkaline. The very interesting experiments of Balfe (1878) show that when taken on an empty stomach the acidity of the urine on the day of administration is only slightly depressed, while on the day following the acidity is considerably higher than on the day before the salt was taken. But when it is administered during the process of digestion the acidity of the urine entirely disappears. This fact is readily explained by the different conditions of the stomach when it is empty and when it contains food. In the former case the acid salt is received into the stomach when its secretions are either neutral or alkaline, and is absorbed undecomposed into the blood; but when, on the other hand, it is taken during digestion, the acid contents of the stomach decompose it, carbonic acid is liberated, and escapes by the mouth, while the alkaline base passes into the system and causes the urine to assume an alkaline reaction. This explanation is, of course, as applicable to the sodium as to the potassium bicarbonate. This salt in ordinary doses of 10 or 15 grains does not appreciably affect the biliary secretion (Rutherford).

In the manner now described bicarbonate of potassium dissolves and eliminates an excess of *uric acid* in the system. Even when *stone* actually exists in the bladder, it lessens the irritability of the organ, diminishing the pain and the frequent necessity of urination. Doubtless, also, its primary action in the *prima viæ* is to neutralize the excessive acidity of their contents, and thus, from the start, to prevent irritation of the nervous system. In *jaundice* depending upon high living or upon malarial poisoning, with enlargement of the liver, dyspeptic symptoms, constipation, and scanty and turbid urine, this salt is of signal advantage. In all of these cases its virtues probably depend upon its power of increasing the alkalinity of the blood and rendering the secretions more liquid. In *cutaneous eruptions* depending upon, or connected with, the previously mentioned conditions its virtues are unquestionable. Although bicarbonate of sodium is more generally employed than the potassium salt in the treatment of *diabetes*, the latter is nevertheless of great utility, and is by some authorities preferred, as promoting more

effectually the elimination of uric acid. It is prescribed in doses of from 30 to 60 grains (Gm. 2-4) in 24 hours, dissolved in about 3 pints of water, which should be taken partly at intervals during and after meals with red wine. As a general rule, it may be stated, according to Balfé, that in cases of acid dyspepsia arising from the excessive formation of acid within the system, as in lithæmia, the alkaline bicarbonates should not be administered before food, but after, and that their administration before meals is indicated in those cases where the free acid is formed in the stomach itself, the result of fermentative changes of undigested food or morbid mucus, when it is necessary to diminish the too high degree of acidity thus caused in order to permit digestion to be properly performed.

POTASSII BICHROMAS, U. S., Br.—BICHROMATE OF POTASSIUM.

Potasse bichromas, Br.; *Kalium bichromicum*, P. G.; *Bichromas kalicus*.—*Bichromate of potash*, E.; *Bichromate de potasse*, Fr.; *Kaliumdichromat*, *Doppeltchromsaures Kali*, G. Formula $K_2Cr_2O_7$. Molecular weight 294.8.

Origin.—The metal chromium was discovered by Vauquelin in 1797 in a Siberian mineral which is composed of chromate of lead, but it is more abundantly found as *chrome iron ore*, which is a compound of chromic and ferrous oxides, $FeO \cdot Cr_2O_3$. It is met with in several localities in the United States, in Russia, and in Sweden, and is used in preparing the bichromate.

Preparation.—The ore is roasted, finely powdered, mixed with carbonate of potassium and chalk, and the mixture strongly heated in a current of air, which oxidizes the iron to ferric oxide, and the chromium to chromic acid, the latter combining with the potassium carbonate to chromate of potassium with the evolution of carbonic acid. To facilitate the oxidation a small portion of nitrate of potassium is sometimes added, but is not necessary; the chalk is used merely for preventing the mixture from fusing. After the roasting has been completed the mass is lixiviated with water, which dissolves neutral chromate of potassium, and the solution, after being acidulated with nitric or acetic acid, is evaporated and crystallized. Sulphuric acid is not as well adapted for this purpose, because the sulphate and chromate of potassium, being isomorphous, would crystallize together. The chrome iron ore may also be roasted with lime, in which case chromate of calcium is formed, which is dissolved in water and decomposed by carbonate or sulphate of potassium. During the year 1876-77 there were 2,471,669 pounds, and in 1881 4,404,237 pounds, of bichromate and chromate of potassium imported into the United States.

Properties.—Bichromate of potassium crystallizes in large yellowish-red transparent four-sided prisms or plates, which are inodorous and are not altered on exposure. The salt melts below a red heat to a transparent dark brown-red liquid, which on cooling crystallizes and finally falls into a crystalline powder. At a white heat the salt is decomposed into oxygen gas, green chromic oxide, and yellow chromate of potassium, which may be separated by dissolving the latter in water. Bichromate of potassium is insoluble in alcohol; it is soluble in water, 1 part of the salt requiring

at	0°	10°	20°	40°	60°	80°	100° C.,	
in	20.14	11.81	7.65	3.43	1.98	1.37	0.98	parts of water (Kremers);
in	21.76	13.51	8.06	3.86	2.22	1.46	1.06	“ (Alluard).

The solution has an orange-red color, an acid reaction, and a bitter styptic, metallic taste, and is deoxidized, with the formation of chromic oxide or chromic salts, on the addition of sulphuretted hydrogen, sulphurous acid, or of sulphuric acid and alcohol, or other organic matters. Heated with hydrochloric acid, chlorine is given off. The solution yields a pale-yellow precipitate with chloride of barium, a yellow one with acetate of lead, and a purplish-red one with nitrate of silver, the three precipitates being soluble in nitric acid. With a cold saturated solution of sodium bitartrate a white crystalline precipitate of potassium bitartrate is produced.

Tests.—As met with in commerce, the salt is usually pure. Its solution in 100 parts of water should not be precipitated on the addition of excess of carbonate potassium (absence of calcium salt), and after having been acidulated with nitric acid should not be disturbed by barium chloride (absence of sulphates) or by silver nitrate (chlorides).

Composition.—The salt is free from water, and represents 31.86 per cent. K_2O and 68.14 CrO_3 ; it may be regarded as a compound of chromic anhydride

Fig. 224.

Crystal of Potassium Bichromate.

with potassium chromate = $K_2CrO_4 \cdot CrO_3$, or as the neutral salt of *dipprochromic acid*, $H_2Cr_2O_7$, which is not known in the uncombined state.

Other Chromates.—CHROMATE OF POTASSIUM, K_2CrO_4 ; molecular weight 194.4. It is obtained by adding carbonate of potassium to a hot solution of the bichromate as long as effervescence is observed; the solution changes in color to yellow, and yields on evaporation six-sided lemon-yellow crystals, which may be fused without decomposition and dissolve in less than 2 parts of water, the solution having an alkaline reaction. It is employed as a reagent.

CHROMATE OF LEAD, $PbCrO_4$, the well-known pigment known as *chrome-yellow*, *Paris yellow*, or *lemon-chrome*, is obtained by precipitating the solution of a lead salt with chromate or bichromate of potassium. It contains 68.9 per cent. of oxide of lead and 31.1 per cent. of chromic anhydride. On being digested with dilute solution of potassa or with chromate of potassium, it parts with one-half of its chromic acid, leaving a bright red basic compound, which, either pure or mixed with more or less chrome-yellow, is used as a pigment under the names of *American vermilion*, *chrome-red*, and *chrome-orange*. A mixture of chrome-yellow and Prussian blue in various proportions constitutes *chrome-green*.

Pharmaceutical Uses.—In the preparation of chromic acid, valerianic acid, and, dissolved in water, as a test liquid.

Medical Action and Uses.—A man after swallowing 3 drachms of bichromate of potassium was seized with vomiting, purging, and severe abdominal pains. The whole body was cold, and the hands shrivelled and blue; the face also was dusky; the breath was cold and the voice feeble. The mouth and throat were dark, thick, bloody mucus was vomited, the thirst was excessive, the pulse feeble and frequent, the respiration hurried, the urine suppressed, and continued so for several days. The patient recovered (*Med. News and Abst.*, Sept. 1881, p. 563). Falck refers to four cases of poisoning by this salt, of which two ended fatally, the doses in the fatal cases being respectively 8 and 15 Gm. (5ii and ʒiv) (*Lehrbuch*, 1880, p. 144). Bichromate of potassium, applied topically, acts like chromic acid, but more mildly. It should therefore be preferred where the full escharotic action of the acid is not required. We have known it to act decidedly as a caustic upon the delicate integument behind the corona glandis when applied for the removal of *venereal warts*. Ordinary warts of the softer sort may generally be destroyed by it.

POTASSII BITARTRAS, U. S.—BITARTRATE OF POTASSIUM.

Potassii tartras acida, Br.; *Tartarus depuratus*, P. G.; *Cremor tartari*, *Kali bitartaricum*, *Bitartras potassicus s. kalicus*.—*Acid tartrate of potash*, *Cream of tartar*, E.; *Bitartrate de potasse*, *Crème de tartre*, *Pierre de vin*, Fr.; *Weinstein*, G.

Formula $KHC_4H_4O_6$. Molecular weight 188.

Origin.—Acid tartrate of potassium is contained in many acidulous fruits, but is collected altogether from the juice of the grape, in which it becomes insoluble after fermentation, and is deposited in the casks in crystalline crusts. These form the *crude tartar* or *argol*, and consist of potassium bitartrate, with calcium tartrate, coloring and extractive matters, and yeast and other vegetable fragments. *Red argol* is deposited from red wines and has a brownish-red color; *white argol*, obtained from white wines, is gray or brownish-white. Crude tartar is not used medicinally, and little is collected in the United States; but the importation of it has increased from 6,965.015 pounds in 1876 to 18,313.544 pounds in 1882, while in the same years the importation of refined and partly-refined tartar has decreased from 2,582.651 to 82.887 pounds, and to 26,448 pounds in 1883.

Purification.—Crude tartar is boiled with water, much of the coloring matter precipitated by the addition of clay, the liquid filtered through animal charcoal or otherwise clarified, and crystallized. The operation has to be repeated several times. The amount of tartrate of calcium contained in crude tartar varies between about 5 and 15 per cent. Although this salt is insoluble in water, it dissolves to some extent (more in hot than in cold) solutions of tartrates; hence it cannot be completely removed from cream of tartar by simple recrystallization. However, the crystals forming on the side of the crystallizing-vats contain less of this impurity than the crusts deposited at the bottom, and by careful management the amount may be reduced to about 3 per cent or less.

To obtain it free from calcium salt, finely-powdered cream of tartar is macerated for 24 hours with 8 or 10 per cent. of hydrochloric acid, previously diluted with water, or it is dissolved in boiling water, the same amount of hydrochloric acid added, and the solution continually stirred while it cools. The mother-liquor is drained off, the crystalline powder washed with cold water, and dried. A considerable proportion of bitartrate of potas-

sium remains in the mother-liquor, and may be utilized in the preparation of tartaric acid by neutralizing it with lime, when tartrate of calcium is deposited.

Properties.—When a hot solution of bitartrate of potassium is rapidly cooled the salt separates in very small crystals, which float on the liquid, and from this behavior it has received the name *cream of tartar*. The larger crystals, which are deposited, were formerly distinguished as *crystalli tartari*. They are rhombic prisms, and quite pure, are colorless, but as usually seen are more or less opaque from the presence of calcium tartrate. But in this form it is rarely kept in the shops, where it is almost exclusively employed in the form of powder. This is white, somewhat gritty, not altered on exposure, inodorous, and has a pleasant acidulous taste and distinct acid reaction. Bitartrate of potassium requires at 15° C. (59° F.) 210 (*U. S.*), 192 (*P. G.*) parts, and at 100° C. (212° F.) 15 (*U. S.*), 20 (*P. G.*) parts of water for solution; it is freely soluble, with the formation of neutral salts, in ammonia and potassa solution, and in solution of alkali carbonates, with the evolution of carbonic acid gas. It is insoluble in alcohol, is more soluble in dilute hydrochloric acid than in water, and is precipitated from this solution by alcohol; the solutions in dilute sulphuric and nitric acids, however, when mixed with alcohol, deposit sulphate and nitrate of potassium. The solutions in alkaline liquids again deposit the salt on being sufficiently acidulated with hydrochloric, acetic, or other acid. When neutralized with potassa or soda the aqueous solution yields with nitrate of silver a white curdy or crystalline precipitate of silver nitrate, which on boiling becomes brown, and then black. When heated in a crucible it evolves inflammable gas and the odor of burnt sugar, and leaves a black residue known as *black flux*, which is a mixture of potassium carbonate and charcoal; the latter is finally consumed on continuing the ignition with free access of air, leaving potassium carbonate or *white flux*. These fluxes are often made by deflagration of intimate mixtures of 2 parts of cream of tartar with potassium nitrate, using 1 part of the latter for the black, and 4 parts for obtaining the white flux. On subjecting potassium bitartrate to destructive distillation, carbonic acid, carbonic oxide, and various hydrocarbons are obtained in the gaseous state; also an aqueous liquid containing much acetic acid, a sublimate of pyrotartaric acid, various tarry products, and, in the retort, carbonate of potassium.

Tests.—The United States Pharmacopeia states that when bitartrate of potassium is treated with a hot solution of potassa whatever remains undissolved is impurity. In this way only the coarser adulterations, such as *terra alba* (see p. 329), sand, etc., or calcium tartrate if present as impurity to a considerable extent, can be detected. Cream of tartar has been adulterated with gypsum, chalk, alum, amylaceous substances (stale bread, etc.). These substances are best detected by treating the powder with an excess of ammonia, wherein it should be completely soluble, and the solution should not be precipitated by hydrosulphuric acid (absence of copper, iron, etc.), and should become merely opalescent by oxalate of ammonium (calcium salts). The residue left by ammonia will acquire a blue color on the addition of iodine if starch is present; cold dilute hydrochloric acid added to the residue will leave *terra alba*, starch, and some gypsum undissolved, and produce effervescence if chalk is present. The acid solution, mixed with an excess of acetate of ammonium or sodium, should not yield white precipitates with ferric chloride (phosphates), ammonia (alumina), or carbonate of ammonium (calcium salt). Chlorides and sulphates are most conveniently detected in the aqueous solution of cream of tartar, which, after addition of a few drops of nitric acid, should not be precipitated by barium nitrate (sulphates) or silver nitrate (chlorides). “204 grains heated to redness till gas ceases to be evolved leave an alkaline residue, which requires for exact neutralization at least 1000 grain-measures of the volumetric solution of oxalic acid.”—*Br.* This test proves the absence of more than 7.8 per cent. of admixtures and impurities. The U. S. Pharmacopeia requires the total absence of sulphate and chloride, but admits not more than 6 per cent. of calcium tartrate; the German Pharmacopœia permits the presence of traces of chloride, and of not more than $\frac{1}{4}$ per cent. of calcium tartrate. For the detection of the latter both pharmacopœias have adopted the test proposed by Biltz: 1 Gm. of the salt is repeatedly agitated and macerated for half an hour with 5 Gm. of acetic acid (*Acidum aceticum dilutum*, *P. G.*); then diluted with 25 Gm. of distilled water (sufficient to make 300 Cem. *U. S.*), and the filtrate (25 Cem. of the filtrate, *U. S.*) is mixed with 8 drops (5 Cem. *U. S.*) of test solution of ammonium oxalate, when it should not become cloudy in less than 1 minute (*P. G.*), nor distinctly turbid in less than $1\frac{1}{2}$ minutes (*U. S.*). The diluted acetic acid (*P. G.*) is nearly identical with the acetic acid (*U. S.*). In the above test with 8 drops of ammonium oxalate a turbidity beginning after $\frac{1}{2}$, 1, or 2 minutes indicates respectively $\frac{1}{2}$, $\frac{1}{4}$, or $\frac{1}{8}$ per cent. of calcium oxalate.

Composition.—Bitartrate of potassium does not contain any water of crystallization. Each molecule contains 1 atom of potassium, and 25 per cent. of its weight is represented by K_2O , and on ignition 36.7 per cent. of K_2CO_3 is left.

Pharmaceutical Uses.—In the preparation of Acid. tartaricum, Antim. et potassii tartras (Antimonium tartaratum), Ferri et potassii tartras (Ferrum tartaratum), Potassii et sodii tartras (Soda tartarata), and Potass. tartras, *Br.* It is an ingredient of Confectio sulphuris, *Br.*, and Pulv. jalapæ comp., *U. S., Br.*

Medical Action and Uses.—In full doses cream of tartar is refrigerant, laxative, and diuretic; the last operation, however, is more evident after small doses given in a large proportion of water. It is apt to disturb digestion by causing flatulence and griping, and, when long continued, to impair nutrition. In excessive doses it may act poisonously, causing vomiting, purging, thirst, colic, and great exhaustion, even to paralysis, which may terminate fatally.

In *febrile* diseases a weak solution of the salt moderates vascular excitement and augments the secretion of urine. For this purpose it is conveniently dissolved in lemonade. As a purgative it is frequently associated with sulphur, magnesia, or jalap. With sulphur or with confection of senna it forms a convenient laxative in cases of *hemorrhoids*. With jalap it is often used as a hydragogue cathartic in *dropsy*, and especially in *anasarca*, and as a diuretic in the same disease, dissolved in an infusion of juniper-berries. With magnesia it has been recommended in *habitual vomiting* arising from gastric acidity, and in pregnancy.

The dose of cream of tartar, as a cathartic, is from $\frac{1}{2}$ ounce to an ounce (Gm. 32–64); as a diuretic, from 60 to 120 grains (Gm. 4–8) in water, largely diluted and taken in divided doses. For the same purpose whey may be employed, prepared by adding 120 grains (Gm. 8) of the bitartrate to a pint of milk.

POTASSII BROMIDUM, *U. S., Br.*—BROMIDE OF POTASSIUM.

Kalium bromatum, P. G.; *Bromuretum potassiumum*, s. *kalicum*.—*Bromure de potassium*, Fr.; *Bromkalium*, *Kaliumbromid*, G.

Formula KBr. Molecular weight 118.8.

Preparation.—Combine 2 ounces of bromine with sufficient iron (1 ounce) in the presence of 24 ounces of water until a green solution is obtained; filter, add solution of $2\frac{1}{8}$ ounces of pure potassium carbonate in 24 ounces of water until it ceases to produce a precipitate; heat the mixture for half an hour; filter, wash the precipitate with hot water, evaporate the filtrate, and crystallize.—*U. S.* 1870. Take of solution of potash 2 pints; bromine 4 fluidounces or a sufficiency; wood-charcoal, in fine powder, 2 ounces; boiling distilled water $\frac{1}{2}$ pint. Put the solution of potash into a glass or porcelain vessel, and add the bromine in successive portions, with constant agitation, until the mixture has acquired a permanent brown tint. Evaporate to dryness, reduce the residue to a fine powder, and mix this intimately with the charcoal. Throw the mixture in small quantities at a time into a red-hot iron crucible, and when the whole has been brought to a state of fusion remove the crucible from the fire and pour out its contents. When the fused mass has cooled dissolve it in the water, filter the solution through paper, and set it aside to crystallize. Drain the crystals and dry them with a gentle heat. More crystals may be obtained by evaporating the mother-liquor and cooling. The salt should be kept in a stoppered bottle.—*Br.*

In the first process ferrous bromide is formed by the action of bromine upon iron, and the solution of this salt, which is of a green color, is decomposed by potassium carbonate, resulting in the production of potassium bromide, which remains in solution, and of a white precipitate of ferrous carbonate; $FeBr_2 + K_2CO_3$ yields $2KBr + FeCO_3$. The latter is very bulky, but by boiling it for some time is converted into a denser ferric hydrate, which is more readily washed out with water than the carbonate. On concentrating the filtrate, crystals of potassium bromide are obtained.

On adding bromine to solution of potassa, 5 molecules of bromide and 1 of bromate of potassium are produced; $3Br_2 + 6KHO$ yields $5KBr + KBrO_3 + 3H_2O$. By evaporating the solution to dryness, mixing the salts with charcoal, and heating to redness, the bromate is deoxidized to bromide, while the oxygen unites with the charcoal, forming carbonic oxide, which escapes; $KBrO_3 + C_3$ yields $KBr + 3CO$. Dissolving in water and concentrating the solution will yield the bromide in crystals. Instead of deoxidizing with charcoal, the same result may be attained by passing sulphuretted hydrogen through the solution, when the hydrogen of the latter will unite with the oxygen of the bromate,

forming water, while sulphur is liberated and requires to be separated by filtration; $\text{KBrO}_3 + 3\text{H}_2\text{S}$ yields $\text{KBr} + 3\text{H}_2\text{O} + \text{S}_3$.

On treating a solution of calcium bromide (see p. 349) with potassium sulphate and filtering from the precipitated gypsum, the liquid will yield potassium bromide, requiring recrystallization for obtaining it pure. The salt is extensively manufactured in the United States.

Properties.—Pure bromide of potassium crystallizes in colorless cubes which are neutral to test-paper. As met with in commerce, the crystals are white, glossy, and, having been obtained from an alkaline solution, have a slight alkaline reaction. It is permanent in the air, inodorous, has a pungent, saline taste, and when heated decrepitates, melts at a dull red heat, and on cooling congeals again to a transparent mass; at a bright red or at a white heat it is slowly volatilized without decomposition. According to Kremers (1856), 1 part of this salt dissolves at 0°C . (32°F .) in 1.87, at 20°C . (68°F .) in 1.55, at 40°C . (104°F .) in 1.34, and at 100°C . (212°F .) in 0.98 part, of water. It is sparingly soluble in alcohol, requiring of it about 200 parts (or, according to Hager, 180 parts) of 90 per cent. alcohol; “it dissolves in 16 parts of boiling alcohol.”—*U. S.* The aqueous solution yields a white crystalline precipitate on the addition of tartaric acid or of a saturated solution of sodium bitartrate, and on the addition of a few drops of chlorine-water liberates bromine, which dissolves in ether, chloroform, or carbon disulphide with a reddish-yellow or brown-yellow color, which in the last two solvents will have a violet tint if iodide be present. 1 Gm. of the powdered and dried salt, when completely precipitated by nitrate of silver, yields, if perfectly pure, 1.579 Gm. of dry bromide of silver.

Tests.—Crystals or fragments of the crystals of the salt laid upon moistened red litmus-paper should not at once produce a violet-blue stain (absence of more than about 0.1 per cent. of alkali).—*U. S., P. G.* A little of the powdered salt taken up with the loop of a platinum wire and held in a non-luminous flame should to the latter at once impart a violet color.—*P. G.* The crushed salt should not with diluted sulphuric acid at once assume a yellow color (absence of bromate).—*U. S., P. G.* 20 Ccm. of a 5 per cent. solution of the salt should not become turbid with 4 drops of a solution of nitrate of barium (*P. G.*), or should not produce an immediate cloudiness or precipitate with 5 or 6 drops of the same test solution (*U. S.*). 1 Gm. of the salt dissolved in 10 Ccm. of water should, after the addition of a few drops of test solution of ferric chloride and of some chloroform, not impart a violet color to the latter (*P. G.*); the same solution, on being mixed with some gelatinized starch, and on the careful addition of a few drops of chlorine-water upon the top of the mixture, should not produce a blue zone at the line of contact of the two liquids (*U. S.*). Both tests prove the absence of iodide. If 3 Gm. of the well-dried salt be dissolved in distilled water to make 100 Ccm., and 10 Ccm. of this solution be treated with a few drops of test solution of bichromate of potassium, and then volumetric solution of nitrate of silver be added, not less than 25.14 Ccm. (*Br.*), and not more than 25.5 (*Br.*), 25.7 (*U. S.*), 25.6 (*P. G.*) Ccm. of the latter should be consumed before the red color ceases to disappear on stirring. 0.3 Gm. of pure potassium bromide would require 25.25 Ccm. of the volumetric solution, but in the presence of 2 or 3 per cent. of potassium chloride 25.6 or 25.7 Ccm. respectively are necessary. A very delicate test for chloride is the following: To a solution of the salt are added bichromate of potassium and sulphuric acid, and the mixture distilled; the distillate will contain *chlorochromic anhydride*, CrO_2Cl_2 , and after neutralization with ammonia will have a yellow color and show the reaction of chromates.

Physiological Action.—*On Animals:* Experiments on various animals demonstrate that the effects of bromide of potassium are not due to the action of the salt upon the nervous centres alone, but upon all the parts which immediately fall under its influence. It is indeed correctly described as a sedative of the heart and of the cerebro-spinal centres, for whether administered to animals by the stomach or hypodermically the following phenomena occur: paralysis of the hind legs and of the thoracic muscles, irregular and feeble action of the heart, paralysis of the iris, evacuation of the bowels, and death, usually by asthenia, but sometimes preceded by tetanic spasms. Paralysis of motion precedes that of sensation, and the loss of both functions is primarily due, not to an impression upon the great nervous centres, but upon the nervous extremities; for the loss of function begins in the extremities and advances toward the spinal cord and brain, voluntary motion and the respiratory act not ceasing until after complete spinal paralysis. Administered by the stomach, the first effect upon the circulation is to produce languor of movement in the capillary blood-vessels, which is due chiefly to the sedative action of the salt

upon the heart, and, as a necessary consequence, a diminution of the calibre of those blood-vessels. The heart, however, continues to beat until all other signs of life become extinct. But if the bromide in a large dose is applied directly to the heart or injected into the veins, death takes place by syncope, the paralyzed heart remaining after death distended. Applied immediately to the capillary vessels, it primarily stimulates and contracts them. The opinion has been advanced, as the result of experiment, that it is not the bromine nor the bromide of potassium, but the potassium alone, which occasions the striking phenomena of sedation in the nervous and muscular systems. It is probable that the diminished frequency and force of the heart may be due to this element, and hence the lowering of the temperature; but no other potassium salt than the bromide diminishes the reflex excitability or occasions sleep, or produces either the acneiform eruption or the group of phenomena described as bromism (Krosz), nor does any other have the slightest influence in preventing epileptiform attacks. That the bromine is essential to the production of these effects is proved by their occurring when, instead of combinations of bromine with alkalies, hydrobromic acid, bromated acetic acid, bromo-benzol, etc. are employed (Steinauer).

On Man: The functional effects of bromide of potassium, generally manifested after the prolonged use of the salt in daily doses of from 40 to 120 grains, are usually such as these: The fetid odor of bromine upon the breath, redness of the soft palate, and an increased or diminished secretion of saliva; diminution, and even abolition, of the reflex sensibility of the palate, the root of the tongue, and the epiglottis, without diminution of the sensibility of those parts to contact and to pain; frequently a craving appetite for food, but sometimes a complete suspension of this function; constipation; some diuresis, or else arrest of the urinary secretion; sedation or complete suspension of sexual desire; diminution and retardation of the menses; pulmonary catarrh; a general heaviness or inertness, drowsiness, diminished clearness of the intellect; sleep, which is generally natural, but sometimes resembles the most profound lethargy; sedation of the excitomotor functions of the spinal marrow and an impairment of the general sensibility; the memory, especially for words, is enfeebled, and they are often strangely misused; eruptions, of acne principally, sometimes of ulcers or boils, or of eczema, appear upon the skin, which grows muddy or bronzed (the presence of bromine in the pustules of acne has been chemically demonstrated). In rare cases a form of eruption occurs in infants which may be described as a hypertrophic or papillomatous dermatitis. The eruption has been compared to a half-ripe raspberry; the papules degenerate, and, if neglected, form sanious ulcers (Parker, *Trans. Clin. Soc.*, xii, 199; Seguin, *New York Med. Record*, xxii, 474). The muscles are enfeebled and their co-ordinated movements imperfect: the gait is unsteady and tottering, and frequently there is loss of flesh. In the more striking cases of bromism the patient is excessively feeble and depressed; the sight and hearing lose their acuteness; the gums are red, swollen, and painful; the nostrils are filled with hardened mucus, and diarrhoea exhausts the strength; there is sometimes profuse sweating or incontinence of urine and feces: pulmonary catarrh impedes respiration, and occasionally death takes place, with febrile symptoms and coma. In exceptional cases mental derangement is superadded, with maniacal violence and hallucinations. It is related that a hemichoreic woman took 610 grains of this salt in three days. "The patient suddenly developed delirium, which continued after the bromide was stopped. Subsequently, she became apathetic and semi-idiotic" (*Med. Record*, xx, 627).

It has been remarked that children of from seven to fifteen years of age tolerate larger doses of the bromide than other persons, and are less apt than adults to become dull and sleepy or to have their muscular co-ordination impaired. This peculiarity is probably due to the rapid elimination of the salt, especially by the salivary glands, the kidneys, and the skin. It is stated that while a nursing mother was taking 30 grains of bromide of potassium daily her infant became emaciated and anæsthetic, and its urine contained potassa. The child speedily recovered on ceasing to use its mother's milk (*Med. Record*, xxii, 336).

All of the phenomena produced by bromide of potassium appear to depend upon its power of restricting the capillary circulation. This seems to be a legitimate inference from the inhibitory and paralyzing influence it exerts upon the spinal nervous system, including, especially, its anaphrodisiac and anti-spasmodic operation, and from its influence on the brain in producing its characteristic sleep and in palliating pain. If, as seems probable, it causes contraction of the capillary blood-vessels, as well as sedation of the heart's action, the phenomena alluded to may be ascribed to these agencies, as may also those morbid alterations of nutrition above described. Since this judgment was written the observations of Dr. Mary Putnam Jacobi on the human brain exposed by an

opening in the cranium have been published. They led to the conclusion that bromide of potassium produces a contraction of the smallest blood-vessels and capillaries, the larger remaining the same; or, in other words, that it limits directly the nutrition, and therefore the activity, of the organ.

Medical Uses.—As is usual in the history of medicines, the virtues of bromide of potassium were discovered accidentally. The high price of iodide of potassium, which is so largely used in the treatment of constitutional syphilis, caused a trial to be made of the bromide in the hope that it might serve as a substitute for the more costly salt. The result showed that the scientific anticipation was totally unfounded, but at the same time it revealed the sedative, anæsthetic, and hypnotic virtues of the medicine, and led to its more suitable use in therapeutics, at first in allaying priapism and other forms of sexual excitement, then in hysteria and in hystero-epilepsy, and finally in epilepsy itself. Since then it has been employed in numerous diseases, especially of the nervous system.

In *sleeplessness* depending upon nervous excitement, exhaustion, and irritability—in hysterical and maniacal wakefulness, for example—rather than upon cerebral hyperæmia as it occurs in sthenic inflammatory diseases, the utility of the medicine is most conspicuous. This fact is not altogether incompatible with the probable theory which ascribes the hypnotic virtues of the bromide to its power of diminishing the amount of blood in the brain, but is more in accordance with the view that it causes sleep by anæsthetizing the organ, precisely as it does in the fauces and other parts when directly applied to them. It is a valuable substitute for opiates in those cases of infantile wakefulness which depend more upon nervous erethism than upon pain or any local disease. In the last-named cases a dose of 10 grains (Gm. 0.60), repeated if necessary, will suffice, but in adults from 20 to 40 grains (Gm. 1.30–4) should be administered every hour or two until the proper effect is secured. This may be promoted by cold ablutions of the head or prolonged tepid general baths.

Neuralgia occurring in connection with general nervous erethism induced by exhausting causes, or with a state of hypochondriac melancholy, with more or less functional derangement of the stomach, heart, etc., or with an overstrained nervous system goaded by unsatisfied sexual desires, has been repeatedly palliated, and sometimes cured, by this medicine. The best result is most apt to be reached in the last-named form of the disease. But a case is on record in which a man of sixty-two, who had suffered from tic-douloureux for 28 years, was completely cured in a fortnight by the daily administration of 100 grains (Gm. 7) of the bromide, given in divided doses (Peter).

In almost all forms of *insanity* attended with excitement and insomnia this preparation is of great value, no other having an equal power of allaying the symptoms with so little risk of injury. In *delirium tremens* it is equally efficient, but it is less so in mania-a-potu. In the latter it should be associated with cold baths. In *chorea* no other medicine exerts as powerful a restraint upon the movements or more frequently leads to a permanent cure. But the greatest triumph of bromide of potassium is shown by its control over *epilepsy*, a disease more intractable than any other that is not inherently fatal. In this connection the experiments of Albertoni are of high interest (*Archiv. f. exp. Pathol. etc.*, xx. 251). In a number of animals he tested the epileptogenous zone on one side of the brain, and found that convulsive attacks were excited by irritating it. He then administered full doses of bromide of potassium until its physiological effects were developed, and, having exposed the sensitive centre of the uninjured side of the brain, he found that irritation of it no longer brought on convulsions. When epilepsy is congenital or is caused by traumatic or other substantial lesions, this medicine, like all others, may be altogether inefficacious. The nearer the disease approaches to a purely functional disorder, the more amenable it is to treatment, and therefore the more so in proportion as it is of recent origin and before those alterations of nutrition have taken place in the blood-vessels and in the substance of the nervous centres which render the disease inveterate. Such, at least, is, as we conceive, the more judicious opinion; but in the judgment of some neither the cause, degree, nor duration of the disease enables one to judge how well or ill it may be affected by the medicine. All are, however, agreed that it must be administered in full doses and for a long time—in daily doses amounting to not less than 60 grains (Gm. 4) and gradually increased as its active power declines. Whether or not radical and absolute cures are ever made of genuine epilepsy is undetermined, but the great preponderance of opinion is unquestionably upon the negative side of the proposition. The most authoritative judgment is, that the epileptic is never secure against a return of his attacks, and that if he is prudent he will, in spite of an apparent cure, continue to use

the medicine at intervals for the remainder of his life, or, as one has phrased it, it should become, as it were, his daily bread. It has been customary in the treatment of epilepsy to employ a prescription containing, besides bromide of potassium, the bromides of sodium, and ammonium, and also the iodide of potassium and the carbonate of ammonium, the whole dissolved in water and flavored with tincture of colombo. The bitter saline taste of this mixture soon renders it very disagreeable to many persons who can take without serious repugnance a simple solution in water of one or more of the salts. It may very well be questioned whether the presence in the above formula of any of the salts except the bromides of potassium and ammonium increases its efficacy.

In *tetanus*, idiopathic as well as traumatic, this bromide has exhibited decided curative powers, and some cases have recovered after enormous quantities of it had been taken. In one successful case about a pound of the salt was consumed in the treatment, and in another 13 ounces were used in 20 days. In *poisoning by strychnia* the results have been equally striking and conclusive, and confirm clinically what physiological experiment had before demonstrated, that bromide of potassium is a true antagonist of strychnia. It is remarkable that a medicine supposed to have a special influence upon the nervous centres connected with the genital organs should not have proved more curative of *hysteria* than of epilepsy itself. Clinical experience, however, shows its influence over hysterical attacks to be very slight and transient; and yet, on the other hand, it is efficacious in certain *local hysterical spasms*, as of the eyelids, œsophagus, and facial muscles, connected with uterine irritation. *Infantile convulsions*, arising from teething and other eccentric causes of irritation, have repeatedly been arrested by this medicine, which may be administered by the rectum if it cannot be given by the mouth in doses of from 5 to 10 grains (Gm. 0.30–0.60), repeated every hour. In some cases of *puerperal convulsions* it has proved equally efficacious, but is probably a less reliable remedy than the anaesthetics. In *whooping cough* bromide of potassium has been employed by the stomach and also by the inhalation of its atomized solution. By the former method the spasmodic element is eliminated in part indirectly, and by the latter through a direct anaesthetic action upon the larynx. In this manner one of the most dangerous factors of the disease is removed. For inhalation there may be used a solution of 2 grains of the salt in an ounce (Gm. 0.12 in Gm. 32) of water. *Spasmodic asthma* has been treated in the same manner, and with notable advantage. *Spasmodic vomiting*, due to reflex irritation, as in *pregnancy*, is sometimes controlled by the bromide, especially when full doses of 60 to 90 grains (Gm. 4–6) are given either by the mouth or the rectum. Usually, the latter mode of administration is to be preferred, or, if the medicine is given by the stomach, it should be in small and repeated doses. It need hardly be remarked that an essential part of the treatment consists in rectal alimentation. For this purpose the pancreatic emulsion is the most appropriate agent. The *vomiting of phthisis*, which is so serious a symptom in the advanced stages of the disease, may generally be controlled by applying a strong solution of the salt to the pharynx and larynx by means of a brush or by atomization. Bromide of potassium appears to be the most successful medicine hitherto used in *sea-sickness*. It should be taken in the dose of about 10 grains in cold water flavored with tincture of ginger, before meals and at whatever times nausea is marked. *Mercurial tremor* and *nervous palpitation* of the heart are favorably influenced by this bromide. The latter affection is oftenest relieved when associated with functional *angina pectoris*.

Bromide of potassium, it has already been stated, even when freely used by healthy persons, blunts or suspends both sexual desire and power, and it has been employed with great advantage when erections of the penis result from morbid conditions either of the sexual organs or of the nervous centres. There is no more efficient preventive of *chordee* produced by gonorrhœa, of the persistent *erections* so frequently met with in infants, and those which sometimes follow the application of cantharidal blisters. The same is true of certain less ordinary cases of persistent *priapism*, as well as of the common examples of nocturnal *seminal emissions*, especially as they occur in young men of chaste life and sedentary habits and in those who have been more or less addicted to self-abuse. Not less serviceable is it in relieving nocturnal *incontinence of urine* in children. It has also been used with excellent results in those cases of hysteroid excitement which verge on *nymphomania*. In these instances large doses of the medicine must be employed. Instead of being administered by the mouth, the bromide may be injected into the rectum or the bladder in cases like those enumerated or of more substantial disease of these organs. A solution of 1 : 20 has been found the most useful. Its anaesthetic virtues are also shown in its allaying the pain of *teething* when it is applied to the swollen gums mixed with honey or in watery solution. It alleviates *toothache* when intro-

duced into a carious cavity. In a lotion the salt palliates the burning and stinging of *urticaria* and the itching in some other diseases of the skin.

Several examples have been published which go to prove that bromide of potassium is occasionally successful in curing *intermittent fever* when quinine and arsenic have failed; and even when, after the cure of the paroxysmal attacks, the *spleen* remains enlarged, it is asserted that no other remedy so promptly and certainly reduces it to its normal dimensions as this preparation. It need not usually be prescribed in larger doses than 15 or 20 grains (Gm. 1-1.30) a day. In the defective sight or *amblyopia* sometimes produced by intemperance this bromide has been found very useful when given in doses at first of 10 grains (Gm. 0.60) three times a day, and gradually increased until its specific effects upon the nervous system begin to show themselves. It probably acts by diminishing the congestion of the cerebral blood-vessels. Several other diseases have been reported to be curable by it, among others *diphtheria*. But an examination of the evidence produced in the discussion of the subject leaves no doubt that this bromide, like all topical applications whatever, has not the least influence on the course and issue of the disease. At best, it may hasten the separation of false membrane from the pharynx, but of this the evidence is far from conclusive.

The association of bromide of potassium with quinine, and also with iron, is said to prevent the headache, throbbing, and general discomfort which some persons experience on taking those medicines, and also the nauseant and depressing effects which occasionally follow the use of opiates.

The anæsthetic action of the medicine upon the *pharynx* and *larynx* has already been referred to in connection with ulcerated states of these organs; the same influence is resorted to for facilitating the use of the laryngoscope, and for lessening the irritability of the *urethra* when the introduction of instruments through it is required. In the treatment of *gangrenous sores* its antiseptic virtues may be invoked.

The *acneiform eruption* produced by the continued use of bromide of potassium, and which with many patients forms a serious objection to its use, may very generally be prevented, as Echeverria first pointed out (1870), by adding to each dose of the bromide from 5 to 8 minims of Fowler's solution. This dose of the latter medicine is entirely too large, and cannot be continued, as it must be to prevent the eruption. Gowers (1878) recommended doses of from 1 to 5 minims, and stated that they need not bear any direct proportion to the degree of the eruption, which, he adds, occurs not only with bromide of potassium, but also with the sodium salt, and still more readily with bromide of ammonium. Duckworth recommends the use of the following lotion: ℞. Precipitated Sulphur ʒij; Spirit of Camphor fʒij; Lime-water fʒij; twice a day after washing the skin with oatmeal gruel instead of soap (*St. Bart's Hosp. Rep.*, xv. 15). In this country Indian corn meal would be preferable. Prowse recommended a solution of 1 grain of salicylic acid in an ounce of water, to be applied frequently (*Brit. Med. Jour.*, Aug. 1880, p. 127).

The commencing dose of bromide of potassium is from 3 to 30 grains (Gm. 0.20-2), according to the age of the patient. It is necessary to repeat the dose several times a day, and in most cases to increase it until its specific effects begin to appear. It should then be reduced or for a brief space of time suspended.

POTASSII CARBONAS, U. S., Br.—CARBONATE OF POTASSIUM.

Potassæ carbonas, Br.; *Kalium carbonicum* (*purum*, s. e. *tartaro*), P. G.; *Carbonas potassicus*, s. *kalicus*, *Potassii carbonas purus*, U. S. 1870; *Sal tartari*.—*Carbonate of potash* (*potassa*), E.; *Carbonate de potasse*, Fr.; *Kaliumcarbonat*, *Kohlensaures Kali*, G.

Formula (K_2CO_3) $_2$ H $_2$ O. Molecular weight 330.

Origin and Preparation.—Carbonate of potassium is contained in many mineral waters, and is met with in the animal economy chiefly after the administration of citrate or tartrate of potassium. Plants take their inorganic constituents from the soil, and when incinerated leave them behind as *ashes*. The ash of most plants contains potassium, sodium, calcium, and magnesium in combination with chlorine, carbonic, sulphuric, phosphoric, and silicic acids, usually ferric oxide, and occasionally some other elements. As a general rule, plants grown near the seashore yield an ash rich in sodium, and those grown inland an ash in which potassium salts predominate. Succulent plants or parts of plants generally yield a larger percentage of ash (calculated for the exsiccated substance) than dry or woody parts. The amount of ash and its constituents necessarily varies to a certain extent, being influenced by the nature of the soil, the age of the plant, and by various other causes; the composition of the ash and of its soluble portion must there-

fore vary for the same species. Among the vegetables which yield an ash rich in potassium salts must be mentioned *corn-cobs*—that is, the fully-developed axis of the fruit-spikes of *Zea Mays*, *Linnae*, after having been deprived of the corn. Examined by H. Ilazard (1872), they were found to contain, on an average, when air-dried, 0.762 per cent. of carbonate of potassium, which may easily be obtained in a nearly pure state; and, estimating the corn crop of the United States at 1,100,000,000 bushels, and 14 pounds of cobs to the bushel, he calculated that 115,000,000 pounds of this alkali could be obtained from that source alone.

At the present time this article is chiefly obtained in those countries, as in some parts of Europe and North America, where wood is cheap or where its transportation to more remunerative markets is too costly, by burning the wood and lixiviating the ashes. The solution is obtained as concentrated as possible by passing the weaker liquids through fresh portions of ash, afterward evaporated and heated in iron vessels, so that on cooling it will solidify to a very hard mass; this constitutes the *crude potash* of the market. This crude potash is of a more or less deep-brown, reddish-brown, or bluish color, due to organic impurities and to iron, copper, or manganese; it is deliquescent on exposure and has a very caustic taste. It is not recognized by any of the pharmacopœias.

Large quantities of potash are at present prepared from the ash obtained from the residue of beet-sugar manufacture, which contains about one-third its weight of this salt, and is freed from other potassium and sodium salts by allowing these to crystallize from concentrated solutions at different temperatures. On washing the fleeces of sheep with water, evaporating the solution, and igniting the residue, an ash is obtained containing but a small percentage of sodium salts and a larger proportion of chloride and sulphate of potassium. The potassium salts obtained in these processes, notably in the former one in large quantities, also the potassium salts from the Stassfurt mines, are by suitable processes converted into potassium sulphate, and this salt into carbonate by a process similar to that of Leblanc for soda (see SODII CARBONAS), by heating the sulphate with lime and charcoal, whereby carbonate of potassium and an insoluble oxysulphide of calcium are formed. Balard (1865) found it advantageous to employ not pure sulphate of potassium, but a salt containing about 20 per cent. of magnesium sulphate, which leaves the product of ignition in a porous condition, so that it may readily be exhausted by water.

Various methods of obtaining carbonate of potassium from other sources have been recommended, and to some extent are used. E. Meyer (1857) proposed to ignite an intimate mixture of 10 parts of *feldspar* (silicate of aluminium and potassium) with from 14 to 18 parts of lime, to boil the mass with water under pressure, and to evaporate the solution, at the same time conducting the products of combustion over the liquid, in order to convert the caustic potassa into carbonate and to precipitate the alumina which was in solution.

1. POTASSII CARBONAS IMPURUS. *U. S.* 1870; Kalium carbonicum crudum. *P. G.*; Cineres clavellati.—Impure carbonate of potassium. Pearlash. *E.*; Potasse impur. *Fr.*; Rohe Potasche. *G.*—This is the white salt, still impure, the preparation of which has been described above. It is at present only recognized by the German Pharmacopœia, which for the anhydrous or nearly anhydrous salt requires it to contain 90 per cent. of potassium carbonate, and 2 Gm. of it to be neutralized by not less than 26.7 Ccm. of normal hydrochloric (or oxalic) acid.

2. POTASSII CARBONAS. *U. S.* 1870; Kali carbonicum depuratum. *P. G.* 1872.—Carbonate of potassium. *E.*; Carbonate de potasse. *Fr.*; Gereinigtes kohlensaures Kali. *G.*—This salt, no longer officinal, but frequently found in the shops, is prepared by treating the preceding with its own weight of cold water, decanting the clear solution, evaporating it in a bright iron vessel, and granulating.

3. OFFICIAL POTASSIUM CARBONATE. For its preparation the following directions were given in the *U. S. P.* 1870: Take of bicarbonate of potassium, in coarse powder, 12 troyounces; distilled water 12 fluidounces. Put the bicarbonate of potassium into a capacious iron crucible; heat gradually until the water of crystallization is driven off; then raise the heat to redness, and maintain that temperature for half an hour. Having taken the crucible from the fire and allowed it to cool, dissolve its contents in the distilled water and filter the solution. Pour this into an iron vessel and evaporate over a gentle fire until it thickens. Lastly, remove it from the fire, and stir constantly with an iron spatula until it forms a granular salt.

When an organic salt of potassium is ignited, the residue left contains carbonate of potassium. Cream of tartar, being the most common salt available for this purpose, was formerly more extensively employed than at present for preparing pure carbonate of

potassium; hence the name *salt of tartar*, which is, however, in the United States usually employed as a synonym for *purified* carbonate of potassium. In making carbonate from the bitartrate of potassium, the latter is usually mixed with saltpetre, which should be entirely free from chloride, and then deflagrated by throwing the mixture in small portions into a red-hot crucible, when the potassium of both the bitartrate and nitrate is left behind as carbonate. In this way *black* and *white flux* are prepared, of which the latter usually contains nitrite of potassium. By exhausting the black flux with water and evaporating the solution a very pure carbonate of potassium is obtained.

Since pearlash contains, besides carbonate, various other soluble salts of potassium and sodium, a pure carbonate cannot be obtained from it, though many of the foreign salts may be removed by the use of cold water in small quantities in which the other salts are less soluble than the carbonate. But by converting the carbonate into bicarbonate the latter salt may be obtained nearly chemically pure, and when heated to redness will give off water and carbonic acid, and leave an equally pure carbonate; 2KHCO_3 yields $\text{K}_2\text{CO}_3 + \text{H}_2\text{O} + \text{CO}_2$. In these operations only silver or clean iron vessels should be employed, for reasons explained under POTASSA.

Properties.—Carbonate of potassium in its pure state is a white inodorous salt, sometimes crystalline, but usually in the form of a granular powder, which has a strong alkaline reaction and a strongly alkaline but scarcely a caustic taste, and is deliquescent in the air, forming a colorless or yellowish liquid of an oily appearance (*Oleum tartari per deliquium*). It is soluble in its own weight of cold water and in two-thirds its weight of boiling water, and from its concentrated solution may with some difficulty be obtained in transparent crystals containing 16.36 per cent. of water. It is insoluble in alcohol, dissolves in dilute acids with effervescence, and has the chemical behavior of potassium salts. Since solutions of sodium carbonate, unless rather diluted, yield with an excess of tartaric acid a crystalline precipitate, it is best to test for potassium with a fragment of the salt attached to the loop of a platinum wire, which should impart a violet but not a permanently yellow color to a non-luminous flame; or, the salt may be dissolved in a slight excess of diluted hydrochloric acid; such a solution will give a yellow precipitate with test solution of platinic chloride and a white crystalline precipitate with a saturated solution of sodium bitartrate. The salt when heated to redness loses between 15 and 18 (about 16 *Br.*) per cent. of water; this exsiccated salt melts at a bright-red heat, and slowly volatilizes at a white heat. The German Pharmacopœia recognizes the anhydrous or nearly anhydrous salt containing at least 95 per cent. of pure potassium hydrate; hence 2 Gm. of it should be neutralized by not less than 27.4 Ccm. of normal hydrochloric or oxalic acid, which indicates 94.5 per cent. K_2CO_3 . 83 grains require for neutralization not less than 980 grain-measures (*Br.*), or 3.45 Gm. of the salt not less than 40.5 Ccm. (*U. S.*) of the volumetric solution of oxalic acid, corresponding to, respectively, 82 (*Br.*) and 81 (*U. S.*) per cent. of K_2CO_3 . Before applying the volumetric test the absence of notable quantities of sodium carbonate should be proven.

Tests.—A solution of the salt in 20 parts of water should not be affected by sulphide of ammonium (metals) nor by ammonium carbonate (alumina); it should yield with an excess of silver nitrate a white precipitate, which on being moderately heated should not acquire a dark color (sulphur compounds). If to the same aqueous solution a little ferrous sulphate, ferric chloride, and an excess of hydrochloric acid be added, the liquid on warming should not become blue (cyanide). If a solution of the salt, prepared with diluted sulphuric acid, be mixed with half its volume of strong sulphuric acid, and a solution of ferrous sulphate be carefully poured upon the mixture, a brown zone should not make its appearance between the two layers (nitrate or nitrite).—*P. G.* "A solution of the salt supersaturated with nitric acid and evaporated to dryness leaves a residue which should be entirely soluble in water or leave merely a trifling amount of insoluble matter (silica); this solution should produce not more than a cloudiness with sodium carbonate (earths, etc.) or with barium chloride (sulphate), or after acidulation by nitric acid with silver nitrate (chloride)."—*U. S.* The German Pharmacopœia directs a 5 per cent. solution for these tests.

Pharmaceutical Uses.—LIQUOR KALI CARBONICI. 11 parts of pure carbonate of potassium are dissolved in 20 parts of distilled water; the solution has the specific gravity 1.330 to 1.334, and 3 parts of it should contain 1 part of potassium carbonate.—*P. G.*

Pearlash is only employed for preparing purified carbonate of potassium. In the preparation of most potassium salts the pure carbonate or the bicarbonate of potassium may be employed. Carbonate of potassium is employed in preparing Atropia, Liquor

arsenicalis, *Br.*; Mistura ferri comp., Potass. sulphuretum, *U. S.*, *Br.*; and for Decoet. aloes comp. and Enema aloes, *Br.*

Medical Action and Uses.—Carbonate of potassium is less irritating than potassa, but more so than the bicarbonate. In large doses it acts as an irritant on the stomach, and even as a caustic when pure. It has been employed in baths in the treatment of *tetanus*, *puerperal convulsions*, *paralysis*, *chronic gout* and *rheumatism*, *glandular swellings*, *suppressed cutaneous eruptions*, etc. In all of these cases it probably acts through its substitutive or its counter-irritant rather than by its alkaline virtues.

Internally, carbonate of potassium has been much used, in common with other antacids, in the treatment of *gouty* and *dyspeptic* conditions attended with a highly acid state of the urine. It is most efficient when the tendency to this form of secretion, which probably depends upon the imperfect oxidation of *effete* matters, is corrected by bitter tonics and hygienic measures. Formerly, theoretical views of the action of alkalies led to the use of carbonate of potassium in various inflammations, membranous and parenchymatous, but especially in those attended with plastic exudation. It was hence much employed in *membranous croup*, *pneumonia*, *peritonitis*, and *glandular enlargements*, and positive assertions were made of its curative powers; their value was, however, greatly impaired by the fact that in general mercury was associated with the alkaline medicine, as well as by leaving out of account the influence of hygienic measures, the natural tendency of the disease, etc. Very probably, subacute inflammations of the *lymphatic glands*, and enlargement of the liver with *jaundice* affecting intemperate eaters and drinkers, have been benefited by this medicine, since, like all the alkaline carbonates, it tends to render the blood more watery, and therefore less nutritive and less apt to produce congestions in parenchymatous organs. In this way, doubtless, it has been profitably used in hepatic and splenic *dropsy*. On the whole, there is nothing in carbonate of potassium to render it superior, or even equal, to the sodium carbonates for any purpose to which alkaline medicines are applied internally.

The dose of carbonate of potassium is from 10 to 30 grains (Gm. 0.60–2). For external use a solution of 120 grains in a pint of water (Gm. 8 in Gm. 500), or an ointment containing from 10 to 60 grains of the salt in an ounce (Gm. 0.60–4 in Gm. 32) of lard, may be employed.

POTASSII CHLORAS, *U. S.*, *Br.*—CHLORATE OF POTASSIUM.

Potassæ chloras, *Br.*; *Kalium chloricum*, *P. G.*; *Kali oxy muriaticum*, *Kali muriaticum oxygenatum*, *Chloras potassicus s. kaliæus*.—*Chlorate of potash*, *E.*; *Chlorate de potasse*, *Fr.*; *Kaliumchlorat*, *Chlorsaures Kali*, *G.*

Formula KClO_3 . Molecular weight 122.4.

Preparation.—Take of Carbonate of Potash 20 ounces; Slaked Lime 53 ounces; Distilled Water a sufficiency; Black Oxide of Manganese 80 ounces; Hydrochloric Acid 24 pints. Mix the lime with the carbonate of potash, and triturate them with a few ounces of the water, so as to make the mixture slightly moist. Place the oxide of manganese in a large retort or flask, and, having poured upon it the hydrochloric acid, dilute it with 6 pints of water, apply a gentle sand heat, and conduct the chlorine as it comes over, first through a bottle containing 6 ounces of water, and then into a large carboy containing the mixture of carbonate of potash and slaked lime. When the whole of the chlorine has come over, remove the contents of the carboy and boil them for 20 minutes with 7 pints of the water; filter and evaporate till a film forms on the surface, and set aside to cool and crystallize. The crystals thus obtained are to be purified by dissolving them in three times their weight of boiling distilled water, and again allowing the solution to crystallize.—*Br.*

On passing chlorine gas into a solution of potassa, hypochlorite and chloride of potassium are formed; $6\text{KHO} + 3\text{Cl}_2$ yields $3\text{KClO} + 3\text{KCl} + 3\text{H}_2\text{O}$. On boiling the solution, or on heating it to between 70° and 80°C . (158° and 176°F.), the hypochlorite is decomposed into chlorate and chloride; 3KClO yields $\text{KClO}_3 + 2\text{KCl}$. The entire reaction, therefore, results in the production of 1 molecule of chlorate and 5 of chloride of potassium, and the two salts must be separated by recrystallization. To avoid the loss of potassium salt, Graham (1841) proposed to substitute an equivalent quantity of lime for five-sixths of the potassa; and this is the process which is now often followed in making the chlorate on the large scale, and the details of which, as recommended by the British Pharmacopœia, have been described above. It has the additional advantage that the previous preparation of caustic potassa is unnecessary. In the presence of water

hydrate of calcium reacts with chlorine in a manner precisely analogous to that of hydrate of potassium, yielding hypochlorite and chloride of calcium (see page 361), and by heat the hypochlorite is decomposed into chloride and chlorate of calcium, the latter of which, by mutual decomposition with carbonate of potassium, produces chlorate of potassium and carbonate of calcium. It will be observed that the reactions in this process are apparently complicated, but, as explained above, the final results are expressed by the equation $K_2CO_3 + 6CaH_2O_2 + 6Cl_2 = 2KClO_3 + 5CaCl_2 + CaCO_3 + 6H_2O$.

Chloride of potassium is now obtained in large quantities, and this salt is advantageously used in the preparation of chlorate by a process very similar to that of Graham, as was shown by Liebig (1842). In this case the reaction results as follows: $KCl + 3CaH_2O_2 + 3Cl_2 = KClO_3 + 3CaCl_2 + 3H_2O$. Or chlorinated lime may be boiled with chloride of potassium, in which case the final products are likewise chlorate of potassium and chloride of calcium.

Potassium chlorate seems to have been known to Glauber (1657); it was described by Higgins (1786) as a kind of saltpetre, and was recognized by Berthollet (1786) as the compound of a hitherto unknown acid. The United States imported 474,598 pounds of this salt in 1876; at present the importation averages about 1,200,000 pounds.

Properties.—Chlorate of potassium crystallizes in colorless, shining plates or in short monoclinic prisms. It is inodorous, has a cooling saline taste and neutral reaction, is permanent in the air, melts without decomposition at $334^\circ C.$ ($633.2^\circ F.$), gives off oxygen at $355^\circ C.$ ($671^\circ F.$); at the same time it forms potassium perchlorate, and at a higher temperature parts with all its oxygen (39.2 per cent. of its weight), leaving 60.8 per cent. of potassium chloride having the properties described below. It requires, at $15^\circ C.$ ($58^\circ F.$), 16.7 parts of water for solution. According to Gay-Lussac, 100 parts of water dissolve

at	0°	13.3°	15.4°	24.4°	35°	49.1°	74.9°	$104.8^\circ C.$,
	3.33	5.60	6.03	8.44	12.05	18.96	35.4	60.24 parts salt.

Gerardin's determinations agree with these results. Ammonium nitrate increases, but ammonium chloride and acetate decrease, the solubility in water (Pearson, 1869). The salt is slightly soluble in ordinary alcohol, but is insoluble in absolute alcohol. It should never be triturated together with sulphur, sugar, tannin, or other readily oxidizable substances except in the presence of water; or, if dry mixtures are to be made, the ingredients should be powdered separately, and mixed by means of a sieve and without friction, in order to avoid violent explosions. As ordinarily met with in commerce, the salt contains traces of calcium chloride, from which it is freed by dissolving it in two or three times its weight of distilled water, and stirring the solution while cooling; it will then be obtained in small crystals, which, after draining and washing with cold water, are pure. The saturated aqueous solution of the salt yields with tartaric acid a white crystalline precipitate of potassium tartrate, and on being warmed with hydrochloric acid becomes greenish-yellow and gives off the odor of chlorine. When strong sulphuric acid is added to chlorate of potassium, *chloric peroxide*, Cl_2O_4 , is formed; this is a yellow, heavy gas, which, in the presence of combustible matter or by a slight elevation of temperature, is decomposed with a powerful explosion into oxygen and chlorine. On adding strong hydrochloric acid to potassium chlorate a deep-yellow, dangerously explosive gas, the *euchlorine* of Davy, is produced: it is a mixture of chlorine and of *chloro-chloric acid*, $Cl_2O_3 \cdot (Cl_2O_3)_2$, which, on being dissolved in water, is decomposed into chlorine and chloric peroxide.

Tests.—The aqueous solution, containing 1 (*U. S.*, 5 *P. G.*) per cent. of chlorate of potassium, should not be precipitated by chloride of barium (sulphate), nitrate of silver (chloride), or oxalate of ammonium (calcium salt), nor should it be colored by hydro-sulphuric acid or by potassium ferrocyanide. The *U. S.* Pharmacopœia permits the presence of a trace of chloride, indicated by a faint cloudiness with the silver test. After heating the salt to redness until gas ceases to be evolved, the residue should have a neutral reaction to test-paper, and should not produce a red precipitate with corrosive sublimate (absence of nitrate).

Pharmaceutical Uses.—Chlorate of potassium is an ingredient of Trochisci potass. chloratis, *U. S. Br.*, and is used in the manufacture of permanganate of potassium and of oxygen. It enters also into the composition of fireworks and of several blasting-powders.

FIG. 225.

Crystal of Potassium Chlorate.

Other Potassium Salts containing Chlorine.—**POTASSII CHLORIDUM**, s. *Kalium chloridum* (chloratum), *Chloruretum potassium*, *Sal digestivum Sylvii*.—(Chloride of potassium, *E.*; Chlorure de potassium, *Sel digestif, Fr.*; Kaliumchlorid, *G.* Formula KCl ; molecular weight 74.4.—It is obtained in large quantities at Stassfurt from *caruallite*, a double chloride of potassium and magnesium, and forms white or colorless, inodorous cubes or quadrangular prisms which have a saline taste resembling that of table-salt, and which are fusible without decomposition. The salt dissolves in 3 parts of cold and a little less than 2 parts of hot water, and is slightly soluble in alcohol, but is insoluble in absolute alcohol. Its aqueous solution should have a neutral reaction, and should yield with saturated solution of sodium bitartrate a white crystalline precipitate, and with silver nitrate a white curdy precipitate soluble in ammonia, but insoluble in nitric acid: the solution should not be affected by barium chloride (sulphate) or potassium carbonate (salts of metals). This salt should not be confounded with potassium chlorate (see above), nor with chlorinated potassa (see page 925). It is largely employed in the manufacture of other potassium compounds, and was imported into the United States during the year 1877–78 to the amount of 19,655,204 pounds, and 43,475,660 pounds in 1882.

POTASSII PERCHLORAS, $KClO_4$, Perchlorate of potassium: molecular weight 138.4. To obtain it, chlorate of potassium is carefully heated until it melts and just begins to evolve oxygen, and is kept at this temperature until gas is no longer given off, and a portion of the residue, on being tested with strong hydrochloric acid, acquires only a faint yellow color. The saline mass is dissolved in water and freed from chloride by recrystallization. Perchlorate of potassium is in colorless rhombic crystals which have a slight saline taste, and when heated to about $400^{\circ} C.$ ($752^{\circ} F.$) is decomposed into oxygen gas and potassium chloride. It is insoluble in alcohol, and dissolves in $5\frac{1}{2}$ parts of boiling water, but requires at $15^{\circ} C.$ ($59^{\circ} F.$) 65 parts, and at $10^{\circ} C.$ ($50^{\circ} F.$) 88 parts, of water for solution.

This salt is employed in preparing *perchloric acid*, which is an ingredient of chlorodyne (see page 440). Bullock (1865) devised the following process: The perchlorate of potassium is distilled with twice its weight of sulphuric acid mixed with $\frac{1}{10}$ part of water. The distillate, containing perchloric, sulphuric, and a little hydrochloric acid and chlorine, is carefully treated with carbonate of lead until the sulphuric acid has been completely precipitated. The liquid is filtered, freed from lead by sulphuretted hydrogen, filtered again, and boiled until it attains a specific gravity of about 1.6, when by distillation it may be obtained of the density 1.693. It is a colorless, oily, very acid liquid, containing 72 per cent. of $HClO_4$, boiling at $203^{\circ} C.$, and not affected by sunlight or by sulphydric, sulphurous, or hydrochloric acid, but readily decomposed by iodine and bromine. The acid is monobasic, forms mostly deliquescent salts, which are also soluble in alcohol, and when added to not too dilute solutions of potassium salts produces precipitates of potassium perchlorate.

Physiological Action.—The large amount of oxygen contained in this salt early led to its being used to cure a variety of diseases which, according to the fashion of the day, were supposed to depend upon putrefactive changes in the blood, etc. These theoretical notions met with their usual fate, and the medicine had been but little used for more than forty years when attention was attracted to it by its power of rapidly healing cancrum oris and aphthous ulcers of the mouth. No sensible effects are produced by it in daily doses of from 15 to 60 grains (*Gm.* 1–4), but in doses of from 1 to 4 or 5 drachms (*Gm.* 4–20) it renders the venous blood everywhere more florid, so that the gums and fauces are of a bright-red color and the teeth are whitened. The appetite is increased, and in children sometimes the bowels become loose, with greenish stools. It increases the flow of urine, and may be recovered from that secretion; sometimes it causes aching in the kidneys. It also passes off with the saliva, the bile, the milk, tears, nasal mucus, and perspiration. It has been known to occasion an erythematous eruption (*Stelwagon*). In excessive doses it may be poisonous. In one case 300 grains (*Gm.* 20) were taken daily for four successive days by a consumptive patient. Obstinate vomiting and severe intestinal pain continued until death, after which inflammation of the mucous coat of the stomach was found. In a second case $\frac{1}{2}$ ounce (*Gm.* 16), largely diluted, was taken early in the morning; diuresis continued during the day, and in the evening vomiting, purging, and cramps occurred, with extreme prostration and a cold blue skin. The urine was scanty and dark, and then suppressed. For a week “violent enteritis, gastritis, and cystitis ensued, with incessant vomiting and intense pain.” Death took place on the seventh day, and on examination the mucous membranes of the whole alimentary tract and of the bladder were disorganized, and crystals of the chlorate were found in the pelves of the kidneys. (For fuller details of this case, as well as on the whole subject, see *STILLÉ, Therapeutics*, 4th ed., ii. 919.) In some protracted cases there is intestinal hæmorrhage, an earthy or yellowish tint of the skin, debility, emaciation, delirium, or coma. In the case of a hearty, well-developed little girl two years and a half old about half an ounce of the dry crystals of the salt had been eaten. The only symptoms were persistent vomiting, with rejection of a portion of the undissolved salt, and a strong inclination to slumber, which became a lethargic condition, and ended in

death after five or six hours. There were no indications of pain (Kennedy, *Am. Jour. Pharm.*, March, 1878). The urine of a girl who died after taking 600 grains of the salt had a sp. gr. of 1055 (Fowler, *Med. News*, xliv. 161).

No less than eleven fatal cases of poisoning by this salt are referred to by Jacobi (1879), besides several others in which, owing to the nature of the disease, diphtheria, doubts may exist respecting the share of the medicine in their issue. In 1880, Wegschneider collected thirty cases of poisoning by chlorate of potassium, but the proportion that proved fatal was not stated (*Bull. de thérap.*, civ. 141). From that date to May, 1884, we have met with the records of ten cases of such poisoning, and of these six were fatal. In 1879 the observations and experiments of Marchand (*Virchow's Archiv*, lxxvii. 455) led him to conclude that potassium chlorate superoxidizes, and so disorganizes, the blood-corpuscles, and renders them incapable of performing their function as oxygen-carriers, and that death from it is either due to this cause or to obstruction of the kidneys with effete blood-disks and (he might have added) crystals of the chlorate. The blood itself remains liquid, and it, as well as all the organs abounding in blood, are of a dark-chocolate color. This condition of the blood has also been observed by Fowler (*loc. sup. cit.*). The spleen is sometimes enlarged. Besides these tissue-lesions it exhibits other evidences of activity. It is antiseptic, but not because it yields oxygen. If it did so it should stimulate the heart, but it depresses that organ, and when injected into the veins of an animal it kills by arresting the heart.

Medical Uses.—The utility of this salt in curing *mercurial salivation* and *mercurial ulcers* of the mouth and throat is now attested by universal experience, but it is not so certain that it acts through the blood after absorption from the stomach, since the same favorable effects are observed when a solution of it is used as a topical application only. That it does not act through any relation it may have to mercury in the system is proved, not only by the fact just stated, but also by its equal efficiency in non-mercurial salivation—as, for instance, when the throat has been injured by caustic potassa—and in like manner in every form of buccal ulceration, as *ulcerative stomatitis*, *aphthæ* (or follicular stomatitis), *gangrenous stomatitis*, *buccal* and *pharyngeal diphtheritis*, and the sore mouth produced by chronic *arsenical poisoning*. Although the contrary has been asserted, it is utterly useless in an affection often confounded with, but very different from, them—*thrush*, or *muguet*, which is a parasitic growth from decomposed milk. It has been used internally, and also topically by atomized inhalation and in simple solution, for the treatment of *croup* (pseudo-membranous laryngitis), and although it may in a slight degree tend to soften the membrane, its favorable influence on the issue of the disease is not well established.

Chlorate of potassium, which has been used by Isambert in the treatment of *diphtheria* with no radical advantage, was subsequently employed by Seeligmüller, who in publishing his results declared it a specific. He prescribed a saturated solution of the salt, or 1 part to 20 of water, to be given in spoonful doses every hour or two hours, day and night, without intermission. In 1877 he wrote as follows: “During the five years that I have ordered no other medicine against diphtheria besides our saturated solution this remedy has proved successful in all cases of diphtheria, except a few that were neglected in the beginning, in which the blood was already profoundly altered, and systemic poisoning had occurred when I was consulted.” He dwells upon the necessity of giving no food or drink immediately after its administration, lest the solution be too quickly removed, and emphatically asserts there is no need of local applications besides, “the internal medication alone being sufficient in all cases.” He, however, recognizes its debilitating influence on the heart’s action, and alludes to one case in which it caused death by gastric irritation. Von Becker, physician to the Children’s Hospital in Vienna (1877), condemns the notion that the medicine is a specific for diphtheria, and warns against the danger of giving it to young children, adding that while it is the mildest, it is also the least efficient, of disinfecting agents. Dr. A. Jacobi of New York spoke of it in 1875 in very similar terms, and in 1879 repeated that it was useful rather as a preventive than as a cure for diphtheria. The dose, according to him, for a child two or three years old should not be larger than $\frac{1}{2}$ drachm (Gm. 2) in 24 hours. A baby of one year or less should not take more than 1 scruple (Gm. 1.33) a day. The dose for an adult should not be more than $1\frac{1}{2}$ drachms, or at most 2 drachms (Gm. 6–8), in the course of 24 hours. The doses he recommends to be administered at short intervals, so that their local impression may be maintained. He also describes the method of Seeligmüller, in order to “raise his voice against it for the reason of its dangerousness.” It should here be mentioned, however, that Seeligmüller greatly reduced the doses of the medicine which he prescribed

(1883). But in the protest against the original plan we heartily join, and not only for the reasons assigned by its author, that the medicine is a powerful cardiac sedative and renders those who largely use it liable to fatal nephritis, but because, in so far as it does good at all in this disease, chlorate of potassium is a mere local stimulant, and diphtheria never yet was cured by local applications merely. They may modify the faucial exudation, in very slight cases may possibly prevent it, but they cannot reach that poisonous element of the disease which constitutes its principal danger, and which is only to be combated successfully by general stimulants and tonics. Cases are reported of diphtheria cured by chlorate of potassium, iron, and food, and similar results from the like combination in certain manifestations of *scrofula*. There can be no doubt that in all of these cases the chlorate, so far as it was internally administered, was quite superfluous. The same remark applies to the alleged cure of the hæmorrhagic diathesis by this salt.

Several physicians have thought that a very dilute solution of this salt has been serviceable in low types of fever, and particularly in *scarlatina* and *typhoid fever*; but the ground of this opinion has, so far, been theoretical rather than practical, and the same remark is perhaps applicable to its alleged utility in *neuralgia*. Another example of the illusions which theoretical speculations may give rise to is the statement that in a case of cardiac *cyanois* it maintained oxygenation of the blood long enough for the patient to accommodate himself to the influence of the malformation under which he suffered; and that in a case of pleural effusion, and in another of pleural hæmorrhage, it sustained life while nature effected the cure. This nature probably did in both instances without reference to the chlorate of potassium. On the same principle have been explained numerous cases of prevented *miscarriage*. Whether the medicine acted as supposed, or acted at all, its virtues in these respects are at least testified to by eminent obstetricians of Edinburgh.

In *ovarian dropsy* it is thought to have removed the disease or arrested its development (*Trans. Med. Soc. State of N. Y.*, 1879, p. 172), but its cures of the sort are neither so numerous nor so well attested as those of *general dropsy* from renal disease. Its diuretic operation has been noted above, and its presence in the kidneys after death, but whether it acts as a direct stimulant of these organs or otherwise, the clinical proof of its efficacy in certain cases of dropsy appears established. It has also been thought to be useful in *chronic cystitis*.

The utility of chlorate of potassium in the treatment of *ulcers* of the mouth naturally led to its use in other ulcerous affections, as those which follow syphilitic *buboes* and other *abscesses*. Its cicatrizing powers are unquestionably very great. In some cases of *phagedenic sores* the pulverized salt has arrested the progress of the disease. Enemas containing it in a moderately strong solution (5j to ʒij–ʒiv) may be used in chronic dysentery, and will tend materially to heal the rectal sores, while those seated higher up in the bowel may be entrusted to astringents or to subnitrate of bismuth. An advantage which this salt possesses as a dressing for gangrenous sores and others discharging a *fætid secretion* is its deodorizing quality; it thus makes a suitable injection in *ozæna*, an appropriate gargle in certain cases of *fætid breath*, etc. A solution of 60 grains in 4 fluidounces (Gm. 4 in Gm. 16) of water may be used for these purposes. In the treatment of *caneroid* the topical application of the salt in strong solution has sometimes been followed by healing of the ulcer, if that existed, and less frequently by a removal of the tumor. But Verneuil declares emphatically that epithelioma was never cured by this agent. He holds that the cases of alleged cure were ulcerated sudoriparous adenomas (*Bull. de thérap.*, xcix. 515).

The *dose* of chlorate of potassium for children under three years of age is about 5 grains (Gm. 0.30) three times a day, and for an adult from 10 to 30 grains (Gm. 0.60–2). It should be dissolved in hot water, and a sufficient quantity of gum and sugar added to suspend the undissolved portion when the liquid grows cold. It is best administered before meals. As a lotion from 15 to 30 grains in an ounce of water (Gm. 1–2 in Gm. 32) may be used. The iodates of potassium and sodium have been proposed as substitutes for the chlorate. On account of its richness in oxygen it is very apt to yield it to other substances associated with it; hence care must be taken that such combinations do not occur explosively. The bodies especially to be excluded from combination with it by friction are the metallic sulphides, glycerin, vegetable powders, as tannin, catechu, etc. In one case an ounce each of tannic acid and chlorate of potassium had been powdered separately, and on being immediately thereafter mixed together an explosion occurred, causing damage to person and property (*Phila. Med. Times*, xii. 512).

CHLORIDE OF POTASSIUM, according to Ringer and Murell's experiments on frogs—1,

paralyzes all nitrogenous tissues; 2, acts by an equal affinity for all protoplasms, and destroys the tissues in the order of vital movement; 3, arrests the heart; 4, by arresting the circulation it depresses the reflex function of the cord in the summer months, indirectly through arrest of the circulation in the brain. What bearing, if any, these results have upon the action of potassium salts upon man, either physiologically or therapeutically, does not appear. It would seem that chloride of potassium is very analogous to chloride of sodium in its remedial powers. It has been called *sal digestivum* on this account; others have attributed to it nervous sedative powers like those of bromide of potassium, and still others an arterial sedative action like that of nitrate of potassium.

Chloride of potassium has been tested as a remedy for *epilepsy* by Dr. Seguin, in consequence of the assertion of Prof. Binz that the virtue of the bromide of potassium in that disease resided in its base. The conclusion arrived at was that chloride of potassium is not efficacious in the treatment of epilepsy.

POTASSII CITRAS, U. S., Br.—CITRATE OF POTASSIUM.

Potasse citras, Br.; *Kalium citricum*, *Citras potassicus* s. *halicus*.—*Citrate of potash*, E.; *Citrate de potasse*, Fr.; *Kaliumcitrat*, *Citronsaures Kali*, G.

Formula $K_3C_6H_5O_7 \cdot H_2O$. Molecular weight 324.

Preparation.—Take of Carbonate of Potassium 8 ounces or a sufficiency; Citric Acid, in crystals, 6 ounces or a sufficiency; Distilled Water 2 pints (Imperial). Dissolve the citric acid in the water, add the carbonate of potassium gradually, and if the solution be not neutral make it so by the cautious addition of the acid or of the carbonate; then filter, and evaporate to dryness, stirring constantly after a pellicle has begun to form till the salt granulates. Triturate in a dry, warm mortar, and preserve the powder in stoppered bottles.—*Br.*

The U. S. Pharmacopœia 1870 had a similar process, directing 14 parts of potassium bicarbonate and 10 parts of citric acid. The solution should be heated to facilitate the extrication of the carbonic acid gas.

The potassium of the bicarbonate or carbonate unites with the citric acid, forming citrate of potassium, while carbonic acid is given off; $3KHCO_3 + H_3C_6H_5O_7$ yields $K_3C_6H_5O_7 + 3CO_2 + 3H_2O$. On evaporating the clear solution, the heat should not be permitted to rise high enough to burn the salt; and continued stirring is necessary toward the end of the process to prevent the salt from forming a hard layer on the bottom of the vessel and to obtain it in a granular condition. When dry it may be triturated in a warm mortar, and may thus be rendered uniformly pulverulent.

Properties.—Citrate of potassium is a white granular, inodorous powder having a neutral or faintly alkaline reaction and a saline and slightly alkaline (feebly acid, *Br.*) taste. It is deliquescent on exposure, dissolves in 0.6 parts of water at 15° C. (59° F.) (*U. S.*), and is more freely soluble in boiling water. It is insoluble in absolute alcohol, and forms with dilute alcohol an aqueous solution upon which a stronger alcohol floats. Its solution gives a white crystalline precipitate with a saturated solution of sodium bitartrate, but it remains clear on the addition of chloride of calcium till it is boiled, when a white precipitate of calcium citrate takes place, which is readily soluble in acetic acid. From its concentrated solution it may be procured in transparent needles which have the above composition and contain $H_2O = 5.55$ per cent. This water of crystallization is not completely expelled until the heat is raised to about 200° C. (392° F.), a portion being retained by the salt as prepared by the above process. At about 230° C. (446° F.) the salt begins to turn brown, and at a higher temperature is completely decomposed, inflammable vapors having the odor of burnt sugar being given off, while potassium carbonate remains behind mixed with charcoal, which is with difficulty completely consumed by continued heating. The salt, heated with strong sulphuric acid, yields a brown liquid, gives off an inflammable gas (carbonic oxide), and evolves the odor of acetic acid. "If 5.4 Gm. of citrate of potassium are ignited until gases cease to be evolved, the alkaline residue should require for complete neutralization not less than 50 Cem. of the volumetric solution of oxalic acid (corresponding to 100 per cent. of the pure citrate of potassium)."—*U. S.* This test recognizes a salt containing 5.55 per cent. or less of water, while the *Br. P.* requires the anhydrous salt, of which 102 grains, heated to redness until gases cease to be evolved, leave an alkaline residue requiring for exact neutralization 1000 grain-measures of the volumetric solution of oxalic acid.

Tests.—The aqueous solution of the salt should not have an acid reaction to test-paper, and should not effervesce on the addition of acetic acid (absence of carbonate) or

produce with it a crystalline precipitate (absence of tartrate). The precipitates produced by chloride of barium and nitrate of silver should be completely soluble in dilute nitric acid.

Medical Action and Uses.—The medicinal virtues of this salt are described under the heads of the SOLUTION and the MIXTURE OF CITRATE OF POTASSIUM, in which forms it is most usually prescribed. In solution it is an arterial sedative and a diaphoretic habitually used in *febrile affections*. Unduly acid urine becomes neutral or alkaline under its administration. Its utility in fever is increased by adding to its solution spirit of nitrous ether or antimonial wine. The *dose* of the citrate of potassium is from 20 to 60 grains (Gm. 1.30–4).

POTASSII CYANIDUM, U. S., Br.—CYANIDE OF POTASSIUM.

Kalium cyanatum, Cyanuretum potassicum s. kalicum.—*Cyanure de potassium*, Fr.; *Kaliumcyanid, Cyankalium*, G.

Formula KCy or KCN . Molecular weight 65.

Preparation.—Mix Exsiccated Ferrocyanide of Potassium 8 parts with Pure Carbonate of Potassium 3 parts, and throw the mixture into a deep iron crucible previously heated to dull redness. Maintain the temperature until effervescence ceases and the fused mass concretes, of a pure white color, upon a warm glass rod dipped into it. Then pour out the liquid carefully into a shallow dish to solidify, ceasing to pour before the salt becomes contaminated with the precipitated iron. Break up the mass while yet warm, and keep the pieces in a well-stopped bottle.

This process was proposed by F. and E. Rogers (1834), and is generally followed in preparing potassium cyanide on the large scale. The reaction is explained by the equation $2\text{K}_4\text{FeCy}_6 + 2\text{K}_2\text{CO}_3 = 10\text{KCy} + 2\text{KCyO} + \text{Fe}_2 + 2\text{CO}_2$, showing that, besides cyanide, cyanate of potassium is also formed, carbonic acid gas is evolved, and iron is separated in the metallic state. Both salts must be well dried before they are mixed, otherwise considerable ammonia is given off; and if the carbonate is contaminated with sulphate the fused mass will contain a corresponding amount of sulphide of potassium. A portion of the product remains in the crucible with the iron, but if it is dissolved with water it becomes contaminated again with ferrocyanide of potassium, which may be regenerated by digestion with sulphide of iron and crystallization to free it from potassium sulphide.

A less profitable process consists in heating dry ferrocyanide of potassium to low redness, and in excluding the air until the residue has cooled. Nitrogen is liberated and escapes, and the cyanide of potassium remains mixed with carbide of iron; $\text{K}_4\text{FeC}_6\text{N}_6$ yields $4\text{KCN} + \text{FeC}_2 + \text{N}_2$.

Cyanide of potassium of the purity required by the U. S. Pharmacopœia is best prepared by generating hydrocyanic acid from 2 parts of potassium ferrocyanide with the requisite quantity of sulphuric acid (see page 66), and conducting the gas into a solution of 1 part of potassium hydrate in 5 or 6 parts of strong alcohol; the bulky crystalline precipitate is drained upon a funnel, washed with strong alcohol, and dried between bibulous paper at a moderate heat.

Properties.—Thus prepared, it is a white granular powder consisting of minute transparent cubes, or after melting at a dull red heat it forms on cooling a white opaque crystalline mass. When perfectly dry it is inodorous, but when moist it is decomposed by the carbonic acid of the atmosphere and has the odor of hydrocyanic acid. It has an alkaline and bitter taste, reacts upon test-papers strongly alkaline, is deliquescent on exposure, and is very freely soluble in water, but is nearly insoluble in absolute alcohol. 80 parts of boiling 90 per cent. alcohol dissolve 1 part of the cyanide; weaker alcohol dissolves it in larger proportion. The aqueous solution dissolves iron, zinc, copper, and nickel, with the evolution of hydrogen, and in the presence of oxygen also silver and gold. The solution yields with a saturated solution of sodium bitartrate a white crystalline precipitate, and with silver nitrate a white curdy precipitate insoluble in nitric acid, but readily soluble in ammonia and in excess of potassium cyanide. The aqueous solution is decomposed on exposure to the air, absorbs carbonic acid, becomes brown, and deposits a dark-brown precipitate; on boiling it is partly decomposed, yielding ammonia and potassium formate. The salt fused in contact with the air is partly oxidized to cyanate, and if fused with sulphur yields potassium sulphocyanide.

Impure potassium cyanide, as obtained by the first process, and which is extensively

used in the arts, has similar properties, but is in white opaque pieces. When dissolved in water the cyanate contained in it is gradually decomposed, with the formation of potassium and ammonium carbonates; $2\text{KCNO} + 4\text{H}_2\text{O}$ yields $\text{K}_2\text{CO}_3 + (\text{NH}_4)_2\text{CO}_3$. In the pure state cyanate of potassium crystallizes in a form similar to that of the chlorate; it is inodorous, and has a saline taste resembling that of saltpetre; it yields with nitrate of silver a white precipitate which is soluble in ammonia and is readily decomposed by heat.

Tests.—The impurities likely to be present in medicinal potassium cyanide are carbonate and chloride. A solution of the salt in 5 parts of water should not effervesce with hydrochloric acid, or should merely disengage isolated gas-bubbles. On heating to redness a mixture of 1 part of the salt with 3 parts of ammonium carbonate, dissolving the residue in water, and acidulating with nitric acid, the solution should give no (or only a faint) turbidity with silver nitrate. The U. S. Pharmacopœia requires the salt to contain at least 90 (94.9 Br.) per cent. of potassium cyanide, which is ascertained as follows: "If 0.65 Gm. of cyanide of potassium be dissolved in 12 Cem. of water, and volumetric solution of nitrate of silver be gradually added, the precipitate first formed should dissolve on stirring, and a permanent precipitate should not appear until at least 45 Cem. (47.45 Cem., Br.) of the volumetric solution have been used."
